An example of the problem that must be resolved is the finding of Richard Goode that the corporation income tax, which he assumes to rest on the stockholder, is progressively distributed because dividend income is concentrated in the upper income brackets (*The Corporation Income Tax* [New York, 1951], pages 73-97). This is true and will result in a more equal income distribution pyramid after taxes. The point here emphasized is that the effect of the corporation tax will still be of concern to the low-income individual who has dividend income and of little concern to the high-income individual if his income does not include dividends. The general tendency of a tax to equalize incomes does not relieve nor in any way satisfy the individual in low brackets subject to a heavy burden while his neighbor may be escaping the burden entirely. Both the general progressivity of the corporate tax and its

possible discriminatory effects are significant but one does not cancel out the other.

Sources of Discrimination. There are two major sources of discrimination in the distribution of the individual income tax burden. First is the discrimination which results from the uneven enforcement of the tax law. This is a problem at all income levels and can be related to source of income and occupation more certainly than income level. Thus while the wage earner and salaried worker subject to deduction at the source pay on almost all their income, the farmer, dividend recipient, professional man, and small businessman are all evaders of the income tax to a much greater extent.

Both available data and the well-known emphasis of the Bureau of Internal Revenue upon the auditing of the returns in the upper income brackets suggest, however, that this problem is greatest at the middle- and low-income levels. Few taxpayers in the top brackets can consistently fail to report reasonably accurately their total taxable income. The more complete records and accounting systems which are maintained by both large-scale business and the upper bracket taxpayer are also conducive to better reporting and enforcement by the Bureau.[4] We may conclude that the underreporting of income for tax purposes, although serious and not entirely confined to any one income level, does not seriously change the impact of progression of the income tax. On the other hand, the sharp discrepancies between the compliance of the farmer, the small businessman, and other self-employed and professional workers and wage and salaried workers can be just as disturbing and seriously threaten the effectiveness of the income tax. To add insult to injury, the use of the standard deduction of 10 per cent tends to make the income tax a gross tax for wage earners with the sole advantage provided by personal exemptions.

The second and more important source of discrimination reduces both the progressivity of the tax and the equity of its application. In this category are the exclusions from income and differential rates of taxation of income from certain sources. Certain of these features of the law are of advantage to only top-income brackets or individuals with substantial property income. The effect in these cases is to reduce the extent and severity of progression at the same time that equity is being violated. In other cases the opportunity to realize the possibilities of tax avoidance is a function of the type of employment or employer, the industry, or even the section of the country in which one lives. Some—and in recent years an increasing number of possibilities—are

[4] Selma Goldsmith, "Appraisal of Basic Data Available for Constructing Income Size Distributions," *Studies in Income and wealth*, Vol. 13 (New York, 1951), pp. 266-327; Simon Kuznets, *op. cit.*, pp. 435-468.

restricted to the aged or related to marital status. The list of possibilities is well known and at this time of year brought to one's attention by tax advisers, investment analysts, and others trying to share some part of the special privileges open to the taxpayers.

Among the important means of reducing the tax burden in the top brackets are the following: tax exemption of state and local bonds, the maximum rate of 25 per cent applied to capital gains realized after six months' holding, percentage depletion, income splitting for married couples, family partnerships and trusts, differed compensation plans and pension plans, stock options, and, finally, the expense account. All income levels can benefit from the following means although the bias in favor of the wealthy is less clear. In every case the possibility is open to only those taxpayers fortunate enough to have income or property in certain forms. The possibilities include: tax exemption of most income in kind with special emphasis upon the rental value of owner-occupied homes, the deduction of mortgage interest, pension and health plans paid for by the employer, fringe benefits if they are not realizable in cash, and, finally, the growing favors extended to those over sixty-five.

As Stanley Surrey has pointed out, "we have a large number of separate tax rates on the books which in combination produces effective rates of tax which are nowhere near what you would expect when looking at our surtax tables." And, also, that "the executive has his stock option, his pension arrangement, his deferred compensation arrangement, and his expense account. The investor has the capital gains rate for his securities and even tax exempt securities along with percentage depletion for his tax exempt oil holdings and capital gains for his coal royalties. The farmer has his livestock sales. Certain partners have splitting of income with their minor children."[5]

Although each of these avenues of tax relief deserves detailed analysis, the limits of this paper prevent more than a cursory treatment. Perhaps the most important quantitatively is capital gains, as it has the double-barreled effect of both reducing the tax on realized gains and permitting the permanent and complete avoidance of any taxation on gains that are never realized but become a part of one's estate. It is here assumed and asserted that capital gains should be included in the concept of taxable income. L. H. Seltzer has presented the most compelling evidence upon this point in his monumental study of the question (*The Nature and Tax Treatment of Capital Gains and Losses,* [New York], 1951). Even if some reservations are still maintained

[5] Statement as discussant at Congress of Industrial Organizations *Conference on Taxation,* Washington, D.C., October 16, 1953, pp. 42-44; and "Policy Issues in Federal Taxation," *Current Business Studies,* No. 10 (Trade and Industry Law Institute, Inc., 1951), pp. 20-29.

on this point, the general acceptance of the market and the professional tax adviser of the fact of many possibilities of conversion of ordinary income into capital gains makes the issue one of major concern for the purposes of this paper. The general assertion of the national income specialists that capital gains cannot be included in economic income must also be questioned on these grounds.

Along with capital gains must also be included undistributed profits of corporations. These have grown in recent years to proportions unheard of in previous periods—in part, as the result of the advantage to top-bracket taxpayers. In the case of the family corporation the possibilities of tax avoidance are most clearly found. Although the law provides for penalties if the retention of earnings is for purpose of tax avoidance or is unreasonable, the record indicates that this has not proved to be an effective method of preventing the widespread use of the corporation as a means of tax minimization. The importance of the family corporation may decline as a result of the explicit legalization of the family partnership, but the large corporation will probably continue to find it acceptable to its shareholders to retain large sums.

Both effects have been subject to some analysis and the results indicate that a signficant variation in the distribution of income before and after tax will result if either one or both are included within the concept of income. As George Garvy has pointed out ("Functional and Size Distributions of Income and Their Meaning," AEA *Papers and Proceedings*, May, 1954, page 246), Kuznets' estimate of the reduction in the share of the total income going to the top 1 per cent between 1939 and 1946 is nearly halved if realized capital gains are included within the income concept (reduced from 2.82 to 1.60 percentage points) and the decline in the top 5 per cent is reduced by one-third (from 5.25 to 3.63 percentage points). It is therefore true that the sums involved are significant for both total revenue realized and its effects upon income distribution. A large and unknown quantity of gains never realized but accruing to the taxpayer must also be mentioned. Due to the failure of the income tax law to require a final settlement of accrued gains on death, these gains can never be accounted for in spite of the fact that the assets involved are valued for estate tax purposes. The donee uses the estate tax valuation as his basis for future gains and of course may transfer the assets again on his death without payment of tax. When the differentials become so attractive as they now are between the capital gains maximum of 25 per cent and the marginal rates applicable to normal income, the continuance of this form of tax avoidance can be expected. Further opportunities have been offered the taxpayer in certain selected cases. These include the granting of capital gains treatment to coal mine

royalties, to farmers on the sale of livestock held for breeding purposes, and to certain stock dividend arrangements.

The extension of the means available to minimize one's tax burden has been a slow but steady process. Not only do the wealthy find means of escape but organized labor, the farmer and the aged are fast catching up. The recent study of J. H. Guttentag, E. D. Leonard, and W. Y. Rodewald of the taxation of fringe benefits indicates the growing importance of this avenue of escape as well as the complexities of dealing with the problem ("Federal Income Taxation of Fringe Benefits: A Specific Proposal," *National Tax Journal,* Vol. VI, No. 3, September, 1953, pages 250-272). Garvy estimates that employer contributions to health and welfare plans alone have increased from 156 million in 1939 to nearly 3.5 billion dollars in 1952. He states that, "together with employer contributions to social insurance funds which are excluded from personal income, they now exceed the monetary interest and the monetary rent components of personal income." (*Op. cit.,* page 243.) When deferred compensation of executive personnel and the growing use of pensions as a measure of tax reduction are considered, we must conclude with Garvy that "the question might be raised to what extent the drift toward equality, which the size distributions for this country show unmistakably, represents changes in the timing of the compensation for services rendered rather than changes in the earning capacity of factors of production." (*Ibid.,* page 244.)

Other students of the trend toward the relief of certain taxpayers have come to conclusions similar to mine. L. H. Seltzer believes that "few persons like to see a baseball game in which there are no runs, no hits, and no errors; or a football game in which no one makes a touchdown. Many congressmen and other persons have a similar feeling about the tax system and the chances of achieving outstanding success. They do not want an airtight tax system. They want to preserve the opportunity for a man to make a financial home run, a touchdown, a killing. The preferential treatment of capital gains has the virtue, in their minds, of offering just such an opportunity." ("Capital Gains and the Income Tax," AEA *Papers and Proceedings,* May, 1950, page 378.) Surrey generalizes somewhat more in his conclusion that "Congress introduces these various low rates maybe because Congress doesn't really accept the principle of progression in the upper brackets. . . . The result is, however, a complete distortion equity-wise among the upper bracket taxpayers. Some do pay these high rates and some don't, even though the average is less than a 50% effective rate." (Congress of Industrial Organizations, *Conference on Taxation,* October 16, 1953, page 43.) Colm finds that "the high rates are largely ineffective because our system has shown its ingenuity in legal tax

evasion and shifts a great deal of luxury comforts of businessmen to expense accounts, thereby making ineffective some of the high rates." (*Ibid.*, page 5.) Walter Heller sums up the indictment neatly as follows: "But growing erosion and corrosion of the income tax base is increasingly raising questions of how far we can extend our reliance on this form of taxation." (*Ibid.*, page 23.)

A final point must be made with regard to income splitting. This feature of the income tax law, introduced in 1948, was designed to prevent a serious and growing inequity in the treatment of married couples in community property and noncommunity property states. The problem became acute when Pennsylvania and some of the other eastern states changed their property law to open this tax haven to their residents. As a result, we now give to all wives a capital value. If any in my audience are still single, I commend to you the computations of Ludwig S. Hellborn. He has estimated the value of the dowry brought to every husband by his wife or, in economic terms, her cash value under the terms of the 1951 law. If your annual income is $5,000, she is worth $11,720. If you have a $10,000 income, she brings you a reduction in annual tax which can be capitalized at $41,360. At $50,000, she becomes worth over a million dollars and may be worth as much as $11,457,000 if your income is $309,000. After this point her value decreases steadily until she becomes worthless, for tax purposes, to a man earning over $1,224,000. ("Uncle Sam's Dowry," *National Tax Association Proceedings*, 1951, pages 310-314.)

This problem is not easily resolved, but the present discrimination against those who choose to remain single has not been solved by either the extension of income splitting advantages to heads of households or the recent and perhaps not unconnected increase in the proportions of the population who have chosen the joys of marriage over the costly freedom of single life.

The Effects of the 1954 Code. Much has been said about the 1954 Revenue Act which for the first time in many years attempted to recodify the basic tax legislation of the nation. This commendable objective was completed within record time but with unfortunate results in the area under investigation. Perhaps the objective of the act was not to promote greater equity in the taxation of equals but it must be judged on these grounds as well as the results achieved in clarification of the law. It is clear that the chemistry of the process of working out the new tax code between the Treasury and Congress resulted in a low valuation of equity in the sense used in this paper. A quick review of the new act indicates that none of the major devices for minimization of taxation has been removed—in many cases they have been extended—and the law has opened some entirely new avenues of escape.

Some of the major sins of commission will be discussed below. The first is the much debated dividend credit which permits the first $50 to be excluded and 4 per cent of the balance of dividend income to be deducted from the tax after the inclusion of all dividend income in the tax base. Although small, this provision gives tax relief of equal value to all brackets. However, as Daniel Holland points out in his paper, the discrimination arising out of the "double taxation of corporate income," if indeed there is real discrimination, declines as the individual reaches higher brackets. One can also complain that although the flat amount deductible may be justified on grounds of administrative convenience and realistic enforcement criteria, the sum available to husband and wife is $100 and is increasingly valuable as family income rises.

The provision of extra exemptions for taxpayers over sixty-five is continued in the new law, and an additional tax allowance of $240 is granted to sweeten the pot. Thus a married couple over sixty-five now receive $2,400 exemptions—a tax credit of $240 above this and the usual standard exemption. In other words, they will not pay any income tax if their retirement income does not exceed $4,000. The advantages of age are further extended by complete exemption of social security payments, and other special provisions for certain types of retirement income. Further relief is granted by extending annuity deductions to recipients who live beyond the period when their capital has been returned. Although this again has the rationale of eliminating a provision of the law confusing and difficult to enforce, the new provisions are even more complex than the old. I find it difficult to justify this trend when the contrast between the position of the older group and those just starting out in life is made. The latter group has little stock to draw upon and cannot wisely expend what little capital they may have. The aged, on the other hand, may well have complete furnishings of a home, adequate clothes to last their lifetime, and can and do expend their capital by purchase of annuities and other means. To claim that the aged have less taxpaying capacity than the young with equal income is a gross miscarriage of justice. The rule of expediency is the only possible justification for the special favors granted. The desire of those who are forced to retire to live more nearly as they had been able to before their reduction in earning power explains the appeal to the aged. But all of us wish to live better or have larger incomes than we do, and it is my guess that if the intensity of the yearning for better things could be measured the young could out-yearn the aged any day. The aging of the population—which is now certain as the result of increased life expectancy and the maturing of the high birth crops of past years—makes this development one of growing significance.

A sore spot for many years past has been further extended by the action of the Congress in the area of percentage depletion. The extension of this feature of the law in 1951 has been continued by both more specific inclusions of certain extractive industries in the high percentage categories and especially the transfer of uranium and a list of some thirty-five domestically mined metals and materials from the 15 per cent to the 23 per cent category along with the long-privileged sulfur. The base for computation of percentage depletion is also somewhat extended, to include as a part of gross income certain treatment processes for talc, magnizite, coal, and phosphate rock. The final extension includes the raising of deductible mine exploration expenses from $75,000 to $100,000. It is of some interest to note that in the case of the granting of the 23 per cent rate to new areas and raising of the exploration expense allowance it was the Senate that took the initiative after the bill had passed the House of Representatives. The Texas plutocracy is still with us, and it looks as though they might be able to dig in and make several more millions before their favored position is brought to an end by public reaction.

Not only mining interests have been able to win special favor. Lumber operators are given capital-gains privileges on net proceeds and the royalties from coal are also given this favor. In the case of coal, the basis for computation of gains is increased in the new code by permitting certain expenses to be included, thus reducing the tax.

We may conclude that in spite of the real accomplishments of the new code in the area of clarification of existing provisions and the prevention of certain abuses due to the lack of clarity in the law, the net effect has been to extend, aggravate, or otherwise enhance the opportunities for tax avoidance.

In all fairness, one must remember that Rome was not built in a day, nor the income tax law destroyed by a single Congress. Most of the difficulties cited above are the responsibility of other Congresses under the leadership of other administrations. Nevertheless, the current outlook has been made more pessimistic by virtue of the failure of the new legislation to correct any of the major shortcomings of the law. When so much emphasis was placed upon the complete revision of the tax code and the desire to develop an integrated law, the results cannot but be disappointing.

Conclusions. It is my conviction that many of the difficulties and inequities of the law as now applied cannot be removed without new and rather radically revised leadership from those who really favor the achievement of an equitable, progressive tax system. I believe that we must face the fact that confiscatory rates of taxation are not acceptable. It is probably true that as long as nominal rates of 70 per cent

and up are continued and they apply to any large number of taxpayers, Congress will continue to provide means of escape. When the possible inequities and real incentives to change business methods which follow from current practices are taken into account, the case for a major drive to clear up this situation is made compelling. It is the suggestion of many—which I share—that if the law were revised to prevent wholesale avoidance, a substantial reduction in top-bracket rates could be accepted in return. This position is further supported by the realization that expenditures on welfare programs can more effectively reduce the sources of inequality of income than can the income tax and at the same time help to increase the total national product.[6] Let us not kid ourselves about the effectiveness of the top-bracket rates. Let us remember that a truly effective income tax with more modest pretensions is worth more than one riddled and weakened for political reasons. It seems to me that the choice now before us is between the salvage of the income tax and the return to a greater dependence upon indirect taxation. The continued threat of a new mobilization program or even the outbreak of war makes immediate action most desirable. Our financial position will be greatly strengthened if these problems were resolved before a new emergency arises. No tax law can be perfect. It is clear, however, that few can be as bad as the current income tax law and still command the respect of any intelligent citizen or economist.

DISCUSSION

WALTER W. HELLER: It is not often that one encounters on one program two papers of such a basically different nature as the two we have enjoyed. Mr. Holland's is essentially a report of findings of painstaking statistical research, supplemented by an appraisal of the new dividend credit in terms of those findings. Mr. Strayer's, in contrast, is a broad-gauged survey of the personal income tax, based on analysis, intuition, and previous research findings. From it, also, policy implications are drawn. It is noteworthy that at the single point of intersection of the two papers, namely, the dividend credit, the two speakers join forces. Both conclude that it is ill-suited to overcome the inequities of our present system of taxing corporate earnings.

Mr. Strayer puts his misgivings about the dividend credit in a broad context of concern, not to say alarm, over the growing inroads on our federal income tax base. I am sure that many of us share his alarm and welcome his well-focused statement of the issues involved. His review suggests ample cause for action to prevent further deterioration and to restore pieces of the base previously chipped away. However, before engaging the forces which are undermining the income tax base, one might be well advised to test not merely their strength but also the rationale of the concessions they seek. Granted, preferential tax treatment offends the dogma of impartiality—"the equal treatment of equals"—which we of the public finance brotherhood hold dear (and rightfully so). But perhaps there are other admissible, even supervening, social and economic ends to be served by the income tax which conflict with our dogma.

Reviewing the whole array of discriminatory features that Mr. Strayer has placed before us, we find that our federal income tax rates, in practice, run from zero on tax-exempt bond interest and imputed income, to preferential rates on capital gains and income from exploitation of mineral resources, to full rates on wage and salary income. To the extent that differentials are the result of disparities in administration (the income tax appears to be about 95 per cent effective on wage and salary income, 75 per cent effective on dividends, and considerably less than that on interest, rentals, and farm income), the discrimination is irrational and indefensible. Rationality begins to enter when we encounter exclusions of imputed income, substitution of standard for actual deductions, special rules on dependents' incomes, and so on. Here, equity stands aside for simplicity of compliance and administration. A desire to stimulate or protect certain types of production and investment—e.g., in enterprises in foreign countries, in oil and gas exploitation, and in risky undertakings generally—motivates other deviations from the rule of equal treatment of equals. Broad social considerations motivate tax differentials between persons above and below the age of sixty-five (through extra exemptions and retirement credits) and between two single people and a married couple with identical incomes (through income splitting).

In reflecting on these departures from "impartiality," each of us would probably admit into his own "ideal" income tax structure some tax differentials

arising out of administrative, economic, and social considerations. The moment we do, of course, we acknowledge the fact that we are in the realm, not of absolute standards, but of a value consensus. Our dogma must make room for careful evaluation of the ends sought by preferential tax treatment, the likelihood that such treatment will achieve these ends, and the price paid in violations of "horizontal equity." In the case of tax concessions to stimulate desired economic activity, for example, one might ask: How large is the marginal social benefit, if any, and what special tax benefits have to be conferred on the favored group, and at whose expense, to achieve it? Where the tax concession involves a large subsidy to special-interest groups but only small third-party benefits, the path of virtue is clear. But where tax differentials do in fact influence resource allocation or income distribution in accord with accepted economic and social objectives, the decision may be more difficult. Granting, then, that the cause for action to restore the income tax base is compelling, one would do well to proceed only after a careful weighing and balancing of benefits and costs.

Turning to the findings of the Holland paper, one may examine them in terms of what they contribute to our knowledge on the taxation of corporate earnings and to the resolution of policy problems and conflicts in this field.

On the first point, previous studies like Richard Goode's 1946 survey for the US Treasury, *The Post-War Corporation Tax Structure,* have shown by arithmetic how the unintegrated corporate-individual income tax overtaxes those in the lower and middle income brackets and undertaxes those in the higher brackets. Illustrations have been developed to demonstrate the impact of varying tax rates and percentages of corporate earnings retention on the amount and pattern of differential taxation. In some cases, *Statistics of Income* data have been used to provide rough approximations of actual distributions and inequalities.

Mr. Holland's excellent study substitutes statistical measurement and precision (within the confines of his assumptions) for arithmetic and approximation. Adopting the central assumption that the corporation income tax rests on profits, limiting his study to taxable dividend recipients, and using the partnership treatment as the criterion of differential taxation, he tells us the following important things about taxes on stockholders: (1) who, by income brackets, was overtaxed and who undertaxed and by how much on the average; (2) the changes in the "crossover income-points" (from overtaxation to undertaxation) during the 1940-50 decade under the impact of shifting relationships (not summarized by Holland in his paper, unfortunately) between corporate and individual tax levels and between retained and distributed earnings; (3) the total number overtaxed (96.8 per cent in 1950) and undertaxed (3.2 per cent in 1950) and what percentage of corporate earnings fell in each category (54 per cent overtaxed; 46 per cent undertaxed); (4) the net overtaxation of stockholders in the aggregate as measured by the revenue that would be lost in shifting to the partnership method (for 1953, 5.7 billion dollars currently plus 1.1 billions in the future); and (5) how the 1954 dividend relief provision affects the pattern of differential taxation.

In short, Holland has greatly strengthened one link in our data chain by quantifying and verifying the tax differentials between dividend recipients and other taxpayers. There are, of course, many other links that must be strengthened before the full dimensions of the problem can be measured as a basis for policy decisions. Three of the important questions that might submit to analysis and statistical inquiry—at least in greater degree than they have to date—are the following: (1) What is the incidence of the corporate income tax; i.e., how much of it is passed forward to consumers and backward to productive agents or absorbed via capitalization by the present owners of stock, thus diminishing the controversial "double burden" on stockholders? (2) What is the amount and pattern of the greatest relative overtaxation of corporate earnings; namely, that which falls on tax-exempt individuals and institutions? (3) What are the actual burdens that fall on undistributed earnings via capital-gains taxes on stockholders?

The first and third of these are exceedingly tough research nuts to crack. Perhaps we lack the tools needed to crack them. But they do raise this question about allocation of available research resources: do we gain more by turning a bright, well-focused light on a segment of the problem that is already fairly well illumined, or would it be better to shed even a little light on the dark, murky corners of the problem that we now submerge in our assumptions? This raises the basic question of what criteria should guide us in allocating research resources. To achieve the optimum allocation requires an accurate balancing of net research products against opportunity costs of various projects. Even with the benefit of hindsight, this balancing process is bound to be inexact. The Holland contribution will undoubtedly be cited as authoritative in its area of inquiry for years to come. Perhaps one should ask no more.

When one turns to the second question (that of what research of this kind can do to resolve the controversy and clear up the misunderstandings to which Mr. Holland refers at the outset of his paper), one finds little basis for optimism.

To resolve controversy in this area requires nothing less than agreement not only on fundamental value judgments concerning the definition of horizontal equity and preferences as to vertical equity, or progressivity, but also on the relative role of incentives and markets in tax policy. These are differences which will not submit to analysis and statistics.

Even without entering this arena of inescapable differences in value preferences and economic persuasions, one is dismayed to find how sharply authorities can differ in their readings of a given set of facts. Thus, Holland concludes: "The tax credit, by providing a constant amount of relief at all income levels, operates in such a way that a greater degree of relief is obtained the higher the stockholders' income level. . . ." Yet Dan Throop Smith, speaking to the National Tax Association last September as a Treasury representative, concluded: "The adoption of relief in the form of a credit . . . gave greater proportionate relief to lower bracket taxpayers." Each has looked into his mirror on the wall, asked which is the fairest of them all, and emerged with answers bearing no resemblance to one another.

Apart from disagreements as to the meaning of available data, one finds

many dissenters from that interpretation of horizontal equity which regards the partnership treatment of corporate income as constituting equal treatment of equals. Those, for example, who regard corporations as more privileged by law than partnerships (because of limited liability, with the implicit residual cost it imposes on society as a whole) may consider differential taxation of corporate earnings as quite consistent with horizontal equity. This would in no sense invalidate Holland's careful work, but would require relocation of his crossover income points to fit individual convictions as to justifiable differentials.

A desire to remove differential taxation may, of course, be quite secondary to distributional and incentive considerations. In recommending a 15 per cent dividend credit, President Eisenhower stated: "This will promote investment which in turn means business expansion and more production and jobs." By identifying more reliably the beneficiaries of dividend tax relief, the Holland study provides a better basis for forming judgments as to possible impacts on investment. But, like most tax research, it is designed to inform the policy-maker rather than to make decisions for him.

This point applies even more forcefully to interpretations of vertical equity. Many of us would agree with Paul Strayer that the largely artificial rates above, say, 70 per cent involve a net loss in terms of distorting incentive effects, stimuli to avoidance and evasion, and unnecessary increments to tax lawyers' incomes. One may safely surmise that this view is shared, probably with some intensity, by the Treasury team of today. Yet, even though the revenue loss from a cut-off at 70 per cent would be less than a half a billion dollars, a frontal assault on the unrealistic top brackets is politically ruled out. ("Only the Republicans can recognize Red China and only the Democrats can adopt a sales tax.") If this be true, an attractive "second best" is to reduce the tax on those components of income which are most unequally distributed. Very considerable progress has already been made along these lines in the capital-gains area. Dividends would clearly be next in line in carrying out such a policy.

This is not to say that lessened progressivity was the prime object of dividend tax relief in 1954. But the action recommended was not inconsistent with this aim. And since methods which are inconsistent with it were rejected even though they would have done a superior job of removing tax differentials (e.g., the withholding method or the corporate dividend credit), one may reasonably conclude that distributional preferences played a considerable role.

Research is indeed indispensable to policy. But the paths from sound statistical research to sound economic policy are seldom straight and narrow.

RICHARD E. SLITOR: Dr. Holland has given us a very thoughtful and lucid preview of his National Bureau of Economic Research study on the combined burden under the corporate-individual tax structure. His findings and analytic contributions will be of real interest to students of taxation, particularly those concerned with the problem presented by an unintegrated corporation-individual income tax system. In the development of its conceptual frame-

work and in its technical craftsmanship, his paper reflects penetrating analysis and skill in an unusually complex and difficult area of applied economics.

Before proceeding further, I wish to make clear that my comments on his paper will be technical and philosophic in character and are not intended in any way to assert or defend a particular policy view on corporate taxation or the double-taxation problem. For reasons which will readily be understood, including the degree of circumspection proper to a civil servant, I am not in a position to examine the rather direct criticisms and recommendations respecting practical tax policy which appear in Dr. Holland's discussion. I can only observe that there seems to be some inconsistency between the careful caveats and reservations at the beginning of his paper where he states flatly that his findings are highly qualified, "valid only within the premises and technique used in their derivation," and the subsequent free-wheeling conclusions where—if he does not throw caution to the winds—he indulges in some fairly uninhibited policy judgments.

My comments on Dr. Holland's paper will deal with three separate points: (1) the major thesis or objective of measuring the combined corporate individual tax burden viewed as a tax on stockholders, which establishes the theoretical framework of the study, (2) the underlying assumptions about incidence, imputation, and investor behavior which go into the development of his findings, and (3) certain procedural aspects.

His study derives its basic inspiration from the idea that the corporate income tax is a kind of personal withholding tax at source on corporate profits. This in itself is a kind of assumption which involves related questions of the rationale of the tax, the economic separateness of the corporation and its stockholders, as well as matters of shifting, incidence, and imputation. Of course, the study may be regarded as a mere pursuit of an extreme set of assumptions to their logical conclusion. But, in practice, the treatment given it, including the author's readiness to draw practical policy conclusions from the results, suggests that the study is more than an exercise in the systematic exploration of certain postulates and premises, but is considered to be based in substantial degree on the most realistic and fruitful analytic approach and assumptions.

Personally, I have always felt that the role of the corporate tax, historically and conceptually, goes beyond that of an ancillary individual income tax. It is unnecessary to recapitulate here the reasons in support of this view, including the traditional concept of the tax on a separate corporate entity recently illustrated by Colm's "partnership in enterprise" principle, as well as what I have referred to as the special role of profits in a high-level economy bolstered by a government commitment to maintain high employment and economic activity and elements of deliberate partial insulation of business earnings from the full impact of the progressive individual rates. Suffice it to say that, to the extent Dr. Holland's study does not embody a realistic concept of the role of corporate taxation, it produces results which, however interesting on other grounds, are not entirely relevant to an appraisal of the actual performance of the corporate tax.

The assumed economic identity of the corporation and its stockholders

involves one of the fundamental unresolved questions not only of taxation but also of other branches of economics. Economists are divided into camps and occupy various intermediate zones of no man's land, depending on whether, or the extent to which, they see through the corporate veil. The particular position taken in the study, therefore, must be taken as a semiarbitrary selection of a particular premise.

It may be answered that, regardless of the conceptual role of corporate taxation, the differential burden with respect to stockholders may be measured on certain assumptions of incidence and imputation of retained earnings. But, in fact, the conceptual role and the assumptions are merely opposite sides of the same coin.

Holland handles the difficult question of incidence with alternative assumptions (except in his partnership-method revenue estimates, where an alternative to 100 per cent incidence on stockholders would modify his conclusions). Certainly he deserves great credit for his refusal to be bemused by apparently conflicting, chaotic views on the incidence problem, judgment on which has threatened to become, in his words, "a matter of taste, not economic analysis." Both from his preference for the standard arguments against shifting and from other indications, I have the impression, however, that he oversimplifies the situation by implying that there is a single, unchanging rule of incidence if it could only be discovered, although opinions on it in the present imperfect state of knowledge differ widely. It seems fairer to recognize that the nature of corporate tax shifting and incidence, or what is left of the concept in the modern macroeconomic setting, varies from situation to situation, with the varying shades of competitive or semimonopoly conditions, and from time to time over different phases of the economic cycle.

If this is true, Holland's assumption of 100 per cent incidence on the stockholder should be treated as a logical extreme and the alternative of 50 per cent incidence at best as a conglomerate average. Tax experts are frequently compelled to furnish a practical, clear-cut view on incidence. On such occasions they mutter darkly, perform certain suitable incantations, and come up with some rule of thumb, such as a specified fraction of shifting, backward or forward. These generalities are sometimes useful, but there is a world of difference between their expression as desperate generalizations and their systematic application to the task of detailed burden measurement in the manner of Holland's study or the more general study by Musgrave and others several years ago.

The imputation of retained earnings to stockholders, which is equally germane to Holland's major thesis, is one which he places on a basis which I consider unrealistic. Such imputation is especially unrealistic in the case of shareholders in large publicly-held corporations, whose control over corporate distribution policy is generally ineffective. Market values of stock not only reflect retained earnings imperfectly, but there may actually be an inverse relationship between retention and market value.

Holland presumably defends 100 per cent imputation on the theory that income to the stockholders is what could be distributed each year without impairing the capital of the enterprise. For this purpose, he takes the accepted

tax accounting concept of income, although he outlines alternative calculations based on current as distinct from historical costs in measuring depreciation and inventory adjustments.

The theory that the earnings of a corporation which may be imputed annually to the stockholders comprises the amount which could be paid out if the firm were liquidated at the end of the year disregards the heavy costs which would be involved in such liquidation. It ignores the possibility that retained earnings may be a cost of competitive survival. Whatever the implications of this possibility with respect to the taxable capacity of the corporation, it suggests reasons why retentions are so imperfectly reflected in market values in either the long or short run. The real values may not be accumulated but eroded in the process of competitive attrition of capital.

Even to the extent there are real accumulations of investment capital over the long run, their allocation among a shifting population of stockholders is uncertain and erratic as a basis for annual income measurement.

All these considerations add up to my conclusion that the imputation of retained earnings along with an allocable share of corporate tax on a dollar-for-dollar basis to stockholders is a misleading basis for measuring the differential burden of the corporate tax. If serious doubt is thrown on this imputation assumption, a difficult question arises in regard to the economic incidence of the corporate tax as between dividends and retained earnings.

Recognition is given in Dr. Holland's paper to the ambiguity of imputing retained earnings to the stockholders, in view of the fact that they could not be used for purposes other than reinvestment in the particular corporation unless distributed or realized subject to further tax payment. He outlines an approximate adjustment for the present discounted value of estimated future capital-gains tax liability based on the assumption that seventy-two cents is added to share prices for each dollar of undistributed earnings. This adjustment adds to the tax on retained earnings but does not scale down the "earnings for retention" themselves for purposes of imputation. There is an apparent inconsistency between dollar-for-dollar imputation for one purpose and settling for seventy-two cents on the dollar for capital-gains tax purposes.

In view of the numerous complications, adjustments, and refinements which Dr. Holland has already patiently taken into account, I feel apologetic in mentioning others which he has apparently neglected. One is the process variously referred to as discounting, amortization, or reverse capitalization of pre-existing corporate tax by current investors in stock. To the extent the existing body of stockholders have taken account of the tax in acquiring their stocks, some observers regard them as not actually paying the tax. Of course, current buyers may have been investors in other corporate equity holdings at some previous time when part or all of a given level of corporate tax was imposed and thus have sustained the tax in that guise.

Another neglected complication has to do with the status of preferred stockholders, especially in nonparticipating issues. While the incidence in this situation is confused and controversial, the tax on the earnings dedicated to the dividends on such issues is sometimes considered to be sustained by the common stockholders.

A further complication is the possibility of spreading or diffusion of the differential burden on common stocks over other investments through the equalization or realignment of yields. To the extent such diffusion has occurred, the double-taxation differential exists but is difficult to isolate or quantify. The resulting general lowering of yields on bonds, real estate, and other assets as well as stocks due to the tax would have become a ubiquitous datum, and the impact of double taxation inextricably interwoven with other complex forces determining the market equilibrium.

Turning from the conceptual framework and assumptions to procedural aspects, the effective rates of combined corporate-personal income tax burden as measured in Dr. Holland's study are the composite resultant of a number of factors. These include: (1) the element of withholding or taxation at source at rates substantially above the lower bracket individual rates, (2) the cushioning of the net differential impact of double taxation as income and marginal personal rate increase (the corporate tax "costs" the dividend recipient less the higher his income since his net after personal tax would be correspondingly less if it were distributed), (3) the insulation or short-circuiting of retained earnings from current application of the individual income tax, (4) the retention ratios of corporations, (5) the configuration of dividend distributions in relation to the income level and applicable personal tax rates of the stockholder, (6) the effects of deficit corporations and dividend distributions in excess of current earnings, and (7) the relative levels of the corporate and individual income tax rate structures.

Throwing together all these factors and grinding out the composite averaged results tend both to blur the focus of analysis and to conceal significant diversities. The equity and economic impact of particular tax arrangements must be judged in terms of the range of diverse possibilities and particular cases, as well as the average results. This comment, I am aware, is like criticizing a tiger for its stripes. These are inherent characteristics of the method of Dr. Holland's study. Nevertheless, they indicate its limitations and inadequacies, if it is to be judged as more than a statistical measurement of tax burden distribution on the stockholder group on the basis of certain limited or extreme assumptions.

In outlining his methodology and explaining the major factors controlling his results, Holland provides two guides for more exact determination of the role of each of the variables entering into the impact of the unintegrated corporate-individual tax structure which prevailed in the years 1940-50. The formulas developed in his paper provide the groundwork for a more schematic analysis and are one of the valuable contributions of the study. The breakdown of the composite differential against stockholders into the major component differentials which, together with the related distribution of dividends and other incomes, produce the final results is another helpful interpretative guide.

Still further light might be thrown on the subject by a further schematic analysis showing, for example, the effect of different retention ratios at different stockholder income levels, varying imputation assumptions, and the varying

net differential attributable to the corporate tax under different levels of individual tax and alternative patterns of rate graduation.

Perhaps because of its limited reliance on the schematic approach, Holland's study fails, on the one hand, to make clear certain relationships which comparatively simple computations would effectively bring out. On the other, it goes to laborious lengths to bring out some broad conclusions which are inherent in, and no more valid than, its assumptions. Some of its conclusions reflect familiar relationships which, on the assumptions, could be predicted without great difficulty in advance.

I am aware that some of my comments have gone beyond the immediate scope of Dr. Holland's study and probably reflect some of my own special, and possibly crotchety, views and preoccupations. Certainly they are intended to be at least partially constructive and do not detract from the basic excellence and substantial interest of Dr. Holland's study.

CONCEPTS OF COMPETITION AND MONOPOLY

COMPETITION: STATIC MODELS AND DYNAMIC ASPECTS

By J. M. CLARK
Columbia University

I. *Introduction*

This paper is an attempt at a contribution to the endless effort to reduce or bridge the gap between theory and reality; and in particular the gap between theories of cost-price equilibrium and theories of production, growth, and development.[1] Theory must always be the department of oversimplification; but dynamic simplifications are at least different from static. They include the tendencies toward equilibrium. But because these tendencies never reach their static limits, dynamic theory cannot use any features which are needed only to enable a model to attain this impossibly precise completeness—especially if these features are incompatible with the conditions of progress.

It follows that fully dynamic theory is bound to lack certain characteristics which are, to many theorists, the essential earmarks of theory. It must accept indeterminateness, with some margin of individual discretion in business action, and uncertainties of different kinds from those they are accustomed to dispose of by assuming a premium for uninsurable risk. Some of these uncertainties are positive aids to effective—not perfect—competition. If such theory is to be accepted as theory, it seems that the first step which theorists can contribute is the setting up of an appropriate conceptual framework, including appropriate tool-concepts. Even within theoretical writings, many or most of the pieces of this framework exist as scattered fragments; but the writer is not aware that the framework has been assembled and articulated. The present paper is a modest attempt to bring together enough pieces to afford some suggestions of what the structure might look like.

II. *The Point of Departure: Existing Competitive Theory*

In the theory of a generation ago, competition played a twofold role: as an agency to eliminate excessive and exploitive profits and as a stimulus to technical progress—a keener stimulus than monopoly would

[1] The remarkable group of papers presented at last year's meetings of this Association and the proceedings of the 1951 conference of the International Economic Association (*Monopoly and Competition and Their Regulation*, E. H. Chamberlin, editor [London, 1954]) include an appeal for a dynamic theory and confirm the existence of an impressive body of factual material large enough to afford a basis for beginnings at fresh generalizations. They present a challenge to which theory should attempt to respond.

afford. As a stimulus to progress, competition included both the carrot and the stick (the carrot of profits to the successful innovator and the stick of losses for those who fall behind) and elimination for those who fall behind substantially and persistently. Temporary monopoly, under the patent system, was also recognized as a force for technical progress. Later, Schumpeter's theory of innovation made its mark, but without being integrated into general competitive theory.

Subsequent developments, leading to the body of competitive theory now prevalent, have concentrated on more precise definition of the conditions necessary to complete or "perfect" cost-price equilibrium—conditions that turn out to be nonexistent. The model then becomes an analytical device and, as such, a step toward explaining why things do not behave like the model, the next step being to take account of the inevitable departures and the conditions accounting for them. So far, this process has produced certain other models, still highly simplified, of monopolistic competition and oligopoly, with and without product differentiation. The preoccupation of these models with cost-price equilibrium is obvious. What may be less obvious is that static limitations are built into their underlying tools of analysis—demand curves and cost curves—which therefore need modification for dynamic purposes.

This prevalent body of theory is not a theory of production, as growth theory must necessarily be. Insofar as it deals with economy and efficiency of production, it does so in terms of optimum or less-than-optimum scale of production (size of plant or firm) on a fixed long-run cost curve; that is, on the obviously static assumption that the "state of the arts" remains constant.

A more troublesome consequence of the model consists of the normative conclusions that are, rightly or wrongly, drawn from it. As a standard of so-called "perfection," it is one-legged, focusing on the essentially static objective of cost-price equilibrium, to the neglect of the dynamic objectives of progress. This one-legged standard is frequently treated, without warrant, as an ideal. And because it is unattainable, all actual or possible conditions are, by comparison, judged inferior, monopoloidal, or actually monopolistic.[2] This interpretation Chamberlin himself has flatly repudiated, stating that perfect competition is not the ideal, and the ideal includes elements of monopoly—which might mean no more than such elements of uniqueness as most businesses inevitably possess.

The idea of the omnipresence of harmful departures from perfect competition seems to underlie the challenge of Professor Galbraith,

[2] The opposite case—of pure but imperfect competition (e.g., agriculture) which tends to be unduly severe—is commonly neglected.

who says in effect: according to theory, our economy ought to be suffering all the evils ascribed to monopoly; why isn't it? Galbraith suggests that it may be the theory that is wrong rather than the facts of the economy, and this contains much truth. But when he suggests that the trouble with the theory is its adherence to competition and recommends throwing competition out the window in favor of a substitute, he is surely overplaying his hand. I would contend that the trouble with the theory is not its adherence to competition, but its too formalized conception of what competition is. This includes, first, the one-legged character of its standard of perfection, and, second, the fact that its picture of reality is highlighted by models of oligopoly and monopolistic competition which do not tell the whole story about the cases with which they deal, and do not do justice to the competitive forces that exist, including forces of progress and forces working toward serviceable—not perfect—cost-price adjustments. The cases include monopolistic evils, but they also include—more typically, I suspect—cases in which the reality behaves better than the models, including the model of perfect competition, which sacrifices important factors of dynamic progress.

But recognition of this lies under a heavy semantic handicap, if it has to take the shape of stating that the ideal includes "elements of monopoly." This raises questions, not as to the facts, but as to the expediencies of the terminology. It seems unfortunate if economists who defend realistic forms of competition thereby expose themselves to the charge of defending monopoly. This danger is not imaginary. The outstanding case is that of product differentiation—a monopolistic element which has in itself no necessary antitrust significance. I have myself said, of product differentiation (*Economics of Overhead Costs*, page 418): "In a sense each competitor has a monopoly of the difference in quality . . . and this qualified monopoly is a feature of the typical 'competitive' market." I would not say he had a monopoly of his product, but only of the quality differential; and I would not suggest this as standard general-purpose terminology, to be used, among other things, in antitrust connections. With such uses in view, it would appear helpful if, in our general-purpose terminology, "monopoly" began with obstructions to imitation, and "incipient monopolization" began with actions of an obstructive character.

There is food for thought in the discrepancies or contradictions between pure theory and practical or policy judgments. For example, theory appears to regard product differentiation as always a shelter from the rigors of competition; but the Interstate Commerce Commission has apparently found that the element of differentiation between rail and truck transport tends to cause their competition to assume a

cutthroat character. And businessmen recognize that a rival's product innovation can be a very aggressive and formidable method of competition. A manufacturer who has no competitors at his immediate location is not for that reason a monopolist under the antitrust laws; but he must watch his step as to what he does with the element of monopoly resulting from his unique location, under the Staley and other basing point cases. On discrimination and freight absorption, neither theory nor antitrust policy is clear and unambiguous. Excess capacity tends to be treated by theory as a monopolistic symptom,[8] but in antitrust cases it may or may not be so treated, depending on circumstances. And businessmen tend to the view that competition does not begin until they have difficulty disposing of capacity output and becomes more severe as excess capacity gets larger.

The perfect competitive market of theory is one in which prices are identical and each producer knows the others' prices and profits, which implies knowing their costs. In practice, too perfect identity of prices is legally suspect, and so is interchange of information on prices, as in open price associations, or information on costs, or even the use of a uniform cost accounting system. All these cases serve to suggest things which current equilibrium models neglect and which dynamic theory may need to recognize.

III. *Dynamic Criteria of Appraisal*

In the light of the things we want competition to do for us, what are the features it needs to have which are implied in these objectives? I will put first the elements required for progress as being most important, since even a small continuing gain outweighs a substantial gain of the once-for-all variety.

First comes progress in economical methods of production. Under competition, this implies that some take the lead and others follow, while managements are changed or firms are eliminated if they fall too far behind. But an excessive rate of elimination of firms may be unhealthy for an industry. To avoid this without retarding progress, the bulk of the followers needs to be able to keep near enough to the leaders to stay in the race.

Secondly, we want competition to afford customers an amply differentiated range of qualities and types of any given product to choose from. This is, of course, wanted for its own sake; but in terms of progress it means that the producers are exploring—and influencing—the customers' preferences and potential preferences, and products evolve in the directions these preferences indicate. Whether they evolve in the best directions is, of course, a different question. Product differentiation

[8] See, especially, Chamberlin, *Theory of Monopolistic Competition* (5th ed.), pp. 109, 171.

costs something, mainly because of the selling effort that is bound up with it. (For that matter, maintaining homogeneity of product costs something, too. And homogeneity of each brand is necessary for effective differentiation between brands.) The combination of selling costs with research and testing introduces an element of overhead cost which makes for large size and limited numbers of producers. But in a market as large as the American, this seldom goes to lengths that spell natural monopoly.

Thirdly, we want new products developed; and this is a necessary correlative of more efficient methods of production, if an increase of 2 per cent a year in productivity is to be absorbed without technological unemployment. New products, even if patented, are generally exposed to imitation and competition after a delay which is, by historical standards, not long.

A second group of objectives is concerned with the diffusion of the benefits of progress, to customers in lower prices or to those who contribute factors of production—chiefly workers—in higher real rewards. This involves a progressive sharing of the rewards of successful innovation, and the sharing becomes complete when the improvement has become part of the generally available state of the arts, from which special profits can no longer be made. This diffusion means that what Veblen called "the wisdom of the ancients" is not "cornered" by current business enterprise; only the recent advances made in it, and these only partially. The diffusion is wanted for its own sake, but it also has a special role in the incentives to progress. What it means is that a renewal of differential profits can be had only by renewed innovation. Thus it is part of the system that can keep incentives to continued innovation alive in full strength. This role would be vitiated if the diffusion were instantaneous and complete, since then innovation would bring no rewards to the innovator. The dynamic system is not one of elimination of profits, but one of erosion and re-creation, both of which are jointly essential.

For the economy as a whole, this process implies the creation, reduction, and re-creation of differential rewards in different industries, as well as for different firms. Professor Harberger's paper at the 1953 meeting developed a case for the thesis that existing differentials are relatively unimportant defects, by conventional utilitarian standards. This argument may not prove that we should be unconcerned about them; but it does strongly suggest that their dynamic impact is more important than their static. The goal is to subject them to active wearing down and prevent them from becoming so enduringly entrenched that they need not be earned and re-earned by progress.

The diffusion process also affects growth via the distribution of in-

comes, which in turn affects the market for the increased flow of goods, new and old, which progress makes available. This has two main dimensions: inequality between persons and between different industries or sectors of the economy. If one sector of the economy is progressive, it will be handicapped in realizing its potentialities if most of the other sectors are too poor to buy much of the products of the dynamic sector and too stagnant to increase their purchases as the productive power of the dynamic sector increases.[4] Development needs to be not too badly unbalanced; and from this standpoint well-diffused competition is favorable. Something similar is true of personal distribution, a fair approach to equality being favorable to the kind of demand on which mass production depends. On the other hand, new products have often been introduced first as luxury items, appealing to the rich or well to do, and later coming within the reach of mass demand, as increased sales and the resulting productive economies reinforced one another cumulatively. Nowadays, with the American mass market thoroughly established, it is sometimes possible to promote a new product for mass volume from the start.

What is not obvious about all this is the part played by competition. It opposes the inequalities of intrenched privilege; but if the labor market were thoroughly competitive, inequalities of wages based on unequal performance might be, by and large, greater than they are. On either basis, however, this country would have a great mass market plus a more limited luxury market, not too far above the mass market and shading into it by easy gradations. Competition also implies mobility of productive resouries, which is needed for adjusting to the inevitable inequalities in rates of growth in different parts of the economy. And in a growing economy, mobility is possible with a minimum of actual shifting of persons or capital.

A phase of this diffusion process is the creating of a market in which a customer may have considerable confidence that the offerings of different sellers are of approximately equal value and that he will not be seriously victimized if he fails to shop around, looking for the best offerings. This (limited) assurance is of real value to the customer who has many demands on his or her time; but it works only if enough customers do shop around. A competitive market tends toward one price to just the extent that customers watch for differentials and take advantage of them. This is the customers' essential role in a competitive system.

A third group of objectives is concerned, not with products and prices, but with the conditions of competitive rivalry in itself. It regards free-

[4] For the suggestion here adopted, I am indebted to R. Nurkse's *Problems of Capital Formation in Underdeveloped Countries* (1953).

dom and opportunity as ends in themselves. It is concerned with the human impact of competitive pressures on those who are exposed to them. But especially it is concerned that efficiency and the diffusion of its benefits should not be dependent on the good will and arbitrary decision of private producers, nor on direct governmental order, but on a situation in which normal business motives impel business units (acting independently) to conduct that will tend to further the desired results. This goal, like the goal of diffusion of gains, is overrigidified in the theoretical concept of an economic law which dictates economic conduct and its results with a precision from where there is no escape.

This would reduce economic freedom to a paradox, since the meaning of freedom resides in a margin of discretion in choosing one's course of action. One of the tasks of the kind of theory here contemplated is to define the margins of discretion that producers have and the margins they should have or can safely be allowed to have. They may, for example, face uncertainties and be governed by longer or shorter perspectives and broader or narrower conceptions of their interests. These all belong in a dynamic theory. The essential limits on private discretionary power are presumably satisified if the discretion of business units does not extend to doing things that obstruct the progress of the "generally available state of the arts" or prevent the public from getting the benefit of it. This is admittedly a not-too-precise standard; and may need some care to avoid tautology, centering in the phrase "generally available." It has a logical kinship with Marshall's "representative firm," and I believe it is not wholly meaningless.

Given these goals, how should one use them to judge a system? A general judgment may be influenced by appraisal of the performance of the system in the large. But for purposes of specific policy in actual cases, rates of progress and fairness of profits are too uncertain, dependent on too many irrelevant circumstances; and their use to determine legality would hardly be consistent with a free private economy. Instead, judgment must hinge on whether conditions are of a sort inherently adapted, by and large, to promote these ends. Three key tests may be suggested: free and independent action, incentive to do the kinds of things that are called for, and capacity to do them.

As to the first, it is not easy to make people compete if they do not want to; but collusion can be checked and protection can be afforded to the more competitively-minded mavericks who will exert pressure on the others. Dynamic change also tends, as we shall see, to keep rivalry alive. As to incentive, mention has been made of the carrot and the stick, of the joint importance of differential gains and their erosion, but no precise optimum rate of erosion appears to be definable. Where progress requires heavy research outlays, atomistic industries are handi-

capped as to both incentive and capacity: as to capacity for obvious reasons and as to incentive because the output of the single enterprise is so small that individual gains fail to measure the importance of the resulting progress for the industry as a whole. Thus in agriculture this element of progress depends heavily (though not exclusively) on governmental research and promotion.

IV. *Elements of Competition as Dynamic Process*

A theory of competition as dynamic process must be not a model but a framework within which many models may find their places, including equilibrium models as limiting hypothetical cases. As I have said elsewhere (*Monopoly and Competition and Their Regulation*, pages 326-328), the process includes initiatory action by a firm, responses by those with whom it deals, and responses to these responses by rival firms, to which one should add the subsequent rejoinders of the initiators, plus any actions that may be taken on a basis of anticipation. (For example, a rival may react defensively, before his customers have time to switch to a competitor.) The moves and the responses may affect productive processes, products, selling efforts or prices, or various combinations. They may be aggressive, defensive, or counteroffensive. Fully dynamic theory needs to conceive these patterns as themselves subject to change, over longer periods of time. Marshall's life history of a firm may be matched by life histories of products or product variants, and of the marketing patterns connected with them. Stages of exploratory introduction, aggressive expansion, defense of established position, and decline—all have different features.

For dynamic theory, a key element is a time interval between moves and responses, or a time distribution of responses; and this time factor is typically essential to give firms an incentive to make competitive moves, by giving them a chance for a temporary gain before their moves are neutralized by the defensive or counteroffensive responses of rivals.[5] Or there may be other elements tending to prevent immediate and complete neutralization.

Perhaps the chief common feature of competitive action is an expectation of a gain that is sure to be eroded; and it is not convincing to make competition hinge on businessmen being so uniformly stupid that they experience this repeatedly without learning to anticipate it. At least the more intelligent must be thinking in terms of a result that will outlast the erosion process: and in this light the decisive motive must be a preference for eroded profit on a larger volume of business,

[5] After writing the above, I find these time elements recognized by A. Henderson: "The Theory of Duopoly," *Quart. Jour. Econ.*, November, 1954, pp. 565, 580. Also by the Civil Aeronautics Board, according to a report of its decision in Air Freight Tariff Agreement case, 14 C.A.B., 424, 428, 430 (1951).

over a similarly eroded profit on a smaller volume. I speak of an "eroded" profit rather than "zero profit," partly because before profit from one successful move is reduced to zero, other moves may have brought other profits, and partly because "zero profit" carries a misleading precision. It is interesting that Chamberlin's tangency theorem for differentiated products involves conduct of the opposite sort: pricing for short-term profit, which after erosion leaves the producer with a smaller volume than he might have had with a more farsighted policy. This can happen; but the diagrammatic proof that it must happen wherever product is differentiated, is unconvincing once one makes adjustments in the concepts of cost and cost curves and demand curves which are needed for dynamic theory.

Cost, conceived as including the minimum return necessary to attract capital and enterprise, includes, under dynamic conditions, large elements of unpredictable obsolescence, thus making zero profit an indefinite, but substantial, quantity. This makes it rational to prefer larger to smaller volume, at zero profit; and this seems clearly to accord with the characteristic American business emphasis on the importance of growth.

As for the envelope cost curve, so frequently used, each point on it must logically represent the most economical method of producing a given output, if a plant could be adapted to that output and never have to change. It takes no account of fluctuations or of growth by substantial-sized units or of provision of reserve capacity to be ready to handle contingent increases, including those which a vigorous sales-promotion campaign might bring, if it proved successful. No competitor likes to expose himself to losing customers to his rivals because he cannot fill their orders promptly enough. Thus on a more realistic curve of cost with scale or size of plant or enterprise, each point would represent, for a given size or expected average output, the average cost that might be expected during the period in which the plant or enterprise remains of this size, allowing for periods when it will be working at part capacity and relatively high average cost and other possible times when it may be working overtime or otherwise be pushed beyond its optimum rate. Such a point would not be on the short-run cost curve but above it, and a long-run cost curve connecting such points would intersect the short-run cost curve, not be tangent to it.

The real point is that the whole range of actual or probable movement on the short-run curve comes into play, not merely the point of supposed tangency. At that point, long-run and short-run marginal cost are equal as drawn, thus obscuring the fact, which is crucial for explaining actual competitive behavior, that at most times short-run marginal cost is quite substantially below long-run marginal cost (which in turn is

likely to differ little from average cost) while occasional peaks of demand may push short-run marginal cost well above both long-run marginal cost and average cost. A firm may price well above marginal cost—pricing for maximum profit as determined by a sloping individual demand curve—and may still fail to cover average cost.

A timeless two-dimensional demand curve of the conventional sort leaves out of account the fact that the effect of a given price, or price differential, on the volume of sales is a function, among other things, of the length of time during which it has been in effect. The effect may reach its limit in time, or may be indefinitely progressive, if the stimulus can be maintained. This time dimension has been recognized at times by economists—generally when they were not speaking as theorists. It means, among other things, that the effect of a given price on sales volume depends on the previous price or price situation; and that the curve is not fully reversible.

A given price may take full effect in minutes (as on a produce exchange) or may take decades where it requires changes in consumers' ways of life which have strong inertia. An example might be the effect of reduced electric rates in stimulating household appliance use of electricity. This case is typical in that the active variable is better described as a price policy than a price, and acts jointly with promotion of the sale of household equipment. Similar comments apply to alterations of the product and moves in the area of sales promotion. This complex of variables would overload any possible system of graphic presentation. A family of three-dimensional surfaces—the third dimension being time—with a different surface for each initial price or price situation, would still be a simplification.

Both for cost curves and demand curves, movements along the long-run curve involve a shifting of the short-run curve, setting up a new one of different dimensions from the former one. In the diagrammatic development of Chamberlin's tangency theorem, the treatment of cost and of demand in this respect is nonsymmetrical. Long-run movements of demand are treated exclusively as unanticipated shifts of the short-run demand curve, and producers are assumed to be governed exclusively by the short-run curve prevailing at the moment and not by longer run expectations. Thus his diagrams utilize a short-run demand curve, placed against a long-run cost curve. A different method could lead to significantly different results.

The responses of those with whom a competitor deals bring in an economic process which is naturally left offstage by equilibrium theory but is essential to dynamics; namely, market canvassing and bargaining. Galbraith has taken advantage of theory's neglect of this process to annex it as one sector of his rather heterogeneous category of counter-

vailing power, treating it as a substitute for competition which has lapsed into passivity. Actually, as theory should have been insisting all along, this activity of customers is a necessary complementary part of the process of competition, serving to bring to bear and make effective the competitive alternatives that may exist. Without it, competition would become passive, though, as earlier noted, many customers can neglect it without serious results if enough others attend to it.

Three grades of customer activity may be distingushed. First, buyers may simply canvass the available alternatives and choose the one they prefer. This increases the cross-elasticity of demand on which the effectiveness of competition depends and tends toward equalizing the attractiveness of different sellers' offerings. Second, some buyers may try to get a better bargain than is currently offered, using their power to shift their patronage as a leverage. It is chiefly the larger buyers who have a chance to do this, and it is likely to result in discriminatory favors, granted frequently (but not exclusively) by the smaller and less powerful suppliers. Letting contracts on a basis of sealed bids is one variant of this process in which one large buyer tries to bring to bear a specially active form of competition for his individual business out of which he hopes to get a differential price. Finally, there is the buyer with real monopolistic power, or bilateral monopoly, in which it seems that almost anything might happen.

V. *Some Applications*

The foregoing ideas suggest, among other things, some modifications in current theorems, including those of pure oligopoly, and the tangency theorem for competition with differentiated products and sloping individual demand curves, tending to reduce the departures of these models from older conceptions of cost-price equilibrium. In the case of pure oligopoly, the indicated modifications begin with the question: Under what conditions is it natural for a firm to expect an increase or decrease in its price to be followed or not followed by its rivals, and how may these expectations be modified by devices available to a firm, other than a simple increase or decrease in its list prices? The suggestion has been made that an increase is more likely to be followed if costs have risen generally. And this possibility can be sounded out by announcing in advance an intended increase, which can be withdrawn if rivals do not follow suit. If there is much unused capacity, a price advance is unlikely to be followed, and existing prices are likely to be subject to downward nibbling. But if prices get ruinously low, a move back toward a more normal level may be followed, though likely to be unstable.

The number of rivals plays a part in that, if unused capacity exists, the actions of the group tend to be controlled by that member whose ideas lead to the lowest price policy. Numbers also play a part in that

the initiator of a price reduction which is not instantly neutralized can stand to gain more than any one of his rivals stands to lose. Thus the outcome may be affected by differences between the slopes of what may be called the aggressive and the defensive demand curves, as well as by differences between the curves envisaged by different firms. More important, perhaps, are devices for making concessions which will not apply to a firm's whole business but mainly—at least for a time—to the added business it hopes to gain. When demand is strong enough to utilize capacity fully, prices would tend to rise under either oligopoly or old-fashioned competition; but the rise under oligopoly may be more moderate because influenced by a longer time perspective. Another mitigating factor is the existence of stand-by capacity, of only moderately inferior efficiency.

As to the case of differentiated products, if this is treated in terms of short-run cost curves, price may be above short-run marginal cost and still be below average cost, and below long-run marginal cost. A fairly typical hypothesis would be that the bulk of production is on a scale sufficient to afford the bulk of the economies of size, implying that the slope of the long-run cost curve is sufficiently flat and uncertain to be an unimportant factor, except for definitely small firms. I cannot conceive a firm deliberately following a price policy which, for the sake of a small price advantage, would condemn it to be one of these small firms when a more aggressively competitive policy might lead to progressive expansion. Such a size-limiting policy involves outright danger to survival, not merely larger or smaller profits.

While competition may emphasize model changes and sales promotion, these in themselves tend to create uncertainty whether a price reduction will be fully and instantly met. Thus they tend to prevent price differentials from becoming so settled in trade custom that a price reduction by one firm is sure to be instantly neutralized by the others. Thus, while competition spurs innovation, innovation in turn helps to keep price competition from settling into an inactive rut.

In both types of case, needless to say, a workably competitive result requires that there be no outright collusion. But it does not necessarily require the ignoring of rivals' probable reactions; merely that their expected reactions should not be so prompt and complete as to wipe out all competitive incentive, either hope of gain or fear of loss from letting others "get the jump." This latter may be the more important factor.

VI. *The Over-all Picture*

The foregoing is a mere fragment of the whole picture. It by no means implies that all industry is satisfactorily competitive. It leaves much room for inequalities in the impact of competitive pressures in different

parts of the economy. The most serious inequalities are those between the pressures of competition in industry and trade, on the one hand, and, on the other hand, the pressures it would produce, if unmitigated, on agriculture and labor. One explanation for this inequality seems to carry the implication that competition in these fields would impose no undue burdens if only industry and trade were not shot through with monopoly, raising the prices of the things workers and farmers buy. Without denying that there is a measure of truth in this, I venture to suggest a different hypothesis as more important; namely, that in industry and trade, the producers' side of the market adjustment is dominated by entrepreneurs' dollar expenses, which will (with qualifications) veto production if receipts do not cover them, while in the case of labor and one-family farming units, the producers' side is a genuine supply schedule which is highly inelastic and may be actually backward-sloping—meaning that a reduction of wages or farm prices tends to result, if anything, in more crops raised, or hours of work offered, rather than less.

This is, of course, not a new idea, but it seems to carry a two-sided consequence. One side is that labor and agriculture might need some mitigation of the pressures of competition, even if the rest of the economy were unqualifiedly competitive. In other words, if we got rid of all monopoly in industry and trade, that might still not make the economy safe for unmitigated competition in labor and agriculture. The other side is that an acknowledged need on the part of labor and agriculture for mitigations of competitive pressures is neither proof nor measure of the dominance of stultifying monopoly in the rest of the economy.

There can be no certainty that competition will remain vigorous in American business. The necessary conditions are a fascinating subject for speculation. Tentatively, they appear to include three mutually interacting areas: public policy expressed in the antitrust laws, the aggressive psychology and adaptability of the American businessman, and the impact of continuous change in techniques, products, and channels of trade, tending to keep things stirred up and uncertain and to prevent competition from lapsing into routine passivity. In the troubled years that lie ahead, this complex of factors is destined at best to an insecure existence. To keep competition healthy requires the traditional eternal vigilance. To recognize competition when we see it, in its present-day forms, requires not only factual study but some reorienting of the traditional framework of theoretical concepts in which the facts may find their interpretation.

REVISED DOCTRINES OF COMPETITION[1]

By SIDNEY WEINTRAUB
University of Pennsylvania

I

Modern doctrines of market competition have now reached legal majority since their birth for public display in 1933. Like many an anxious parent bewitched by the enigma of whether their offspring are prepared for life, both Mrs. Robinson and Professor Chamberlin have recently been analyzing their intellectual progeny, betraying particular concern with the frailties of their creations. Mr. R. F. Harrod, too, with some priorities in this intellectual genealogy, has been lamenting some antics of his slightly later-born, lucid and renowned "Doctrines of Imperfect Competition";[2] an air of urgency covers the transformation that he desires to impart to his fondling.

Let us consider the recent parental diagnoses and precepts, some of which will arouse neighborly head-shaking. Later, brief attention will be paid to a few rebellious playmates of their prodigies.

II

I deal with Mr. Harrod's beliefs first and at greater length, for I surmise that from a doctrinal standpoint the issues raised are paramount. Necessarily, it is the total impact of the argument, omitting qualifications, that is sought.

Harrod proposes, first, to discard the doctrine of excess capacity, largely deduced from the tangency acrobatics, as incompatible with his new attitude on price formation. Thence he argues that it is increasing returns and not imperfect competition which is the causal culprit pushing output from the social optimum. All points devolve from the revised theory of price determination, with the first being an implication of it while the belaboring of increasing returns constitutes a revived scent in the old hunt for *the* social devil.

Driving up to his price doctrines, Harrod denounces as "altogether wrong" the "generally accepted" opinions on the alleged excess capacity defections of imperfect competition as being based on faulty and contradictory hypotheses of entry and short-period profit maximization. He assures us that "any experienced man of business would pronounce it most 'unsound' to make a temporary surplus profit by charging a

[1] I should like to thank Dr. Almarin Phillips, of the University of Pennsylvania, for several useful observations.

[2] *Quart. Jour. Econ.*, May, 1934. Reprinted as "The Theory of Imperfect Competition Revised," in his collection of *Economic Essays* (Harcourt, Brace, 1952). All quotations below are drawn from this source.

high price at which it is known that sales are unlikely to be . . . maintained in the long run. It is surely wrong for economists to insist . . . that this is none the less what entrepreneurs normally do" (page 147). If competition increases, he avers, all investment is "too large." So right from the start the price is designed to fend off potential competition.

Criticising the tradition further he asserts: "The radical mistake is in assuming that as soon as he has his plant he [the entrepreneur] forgets about long-period marginal revenue."[3] But "long-period considerations on the demand side remain just as relevant to day-to-day pricing policy, after the plant has been constructed as it was before" (page 150). Hence, with "free or relatively free entry, the entrepreneur . . . will plan to charge a price yielding only a normal profit" (page 151)—defined as a sum which the entrepreneur would "deem just sufficient" when contemplating a plant extension.

This provides ample clue to Harrod's conception of the pricing process. Unmitigated pecuniary myopia and malevolence are supplanted by secular prudence and beneficence. Fair long-run price exactions expel maximum short-run extortions in this quick overturn of dogma. Mr. Hyde is Dr. Jekyll again and we are expected to lie in comfortable repose with him. Once implored to defer to the view that firms always respired in short-run exhilaration,[4] we are now beseeched to accede that they are never wholly elated, but instead are pensively aglow in contemplating a long-run thrill to cap their short-run frustration.

All this stems from his doubts, pursuant to the well-known Oxford price queries, whether entrepreneurs "act under the pure motive of profit maximization" (page 139). Yet the entrepreneurs of his image behave in precisely this way, given only a longer price horizon. Plant layout, output, and price are of an order to entail the tangency of the long-period demand and cost curves. But the "equilibrium does not entail the presence of excess capacity. The old doctrine was partial and . . . incorrect, because it considered pricing policy in isolation from investment policy. The new doctrine rests on an integrated theory of investment and pricing policy" (page 162).

Readers who have followed the "full cost" controversy in the *Economic Journal* will be aware of the kinship of Harrod's ideas to those of Mr. Andrews.[5] Interestingly, Harrod contends that marginal and full-

[3] Rightly, and long overdue, he points out (p. 149) that the planning curve yields an erroneous solution if demand changes. Yet this is only part of the case against this technique. See my "Limitations of Planning Curves," *So. Econ. Jour.*, October, 1950.

[4] See Harrod's *Trade Cycle* (Oxford, 1936), pp. 75-76, where he declares that "entrepreneurs arrange matters in the short period, so far as they can, to make marginal revenue equal to marginal cost." Although a qualification is made for user cost, the over-all impression is that of short-run maximization.

[5] See the review article by E. A. G. Robinson, "The Pricing of Manufactured Products," *Econ. Jour.*, December, 1950, and discussion, M. J. Farrell, A. Silberston, and E. A. G. Robinson, *ibid.*, June, 1951.

cost analyses can be joined, with the latter providing the entrepreneurs with "a shorter and manageable way of reaching the same result as he would if he could assess these elusive [marginal] quantities." Compatibility, however, is "subject to the proviso that the entrepreneur dare not charge a price above full cost without rendering his market vulnerable . . . " (pages 161-162).

An integrated theory of investment and pricing, as well as the marriage of the contesting price theories, would, if consummated, merit applause. Yet the ideas promulgated sometimes appear deficient and incomplete. Under the space limitations operative, arguments will have to be brief.

First, there is one form of the theory of long-run maximization that is wholly barren and tautological. At least the theory that firms maximized short-run pecuniary profits was in principle operationally testable. But to declare that firms maximize long-run profits could preclude verification, for in a dynamic setting this fact could only be solidly established on a retrospective probe; even then, if the firm succeeded in blocking competitor entrants, it would be fuzzy without information on the profits that would evolve with entry and adherence to a short-run maximization policy. Only an omniscient mind could test this hypothesis. Of course, it may be alleged that businessmen seek to maximize their long-run profits, not that they succeed. This is a very different theory indeed. Inevitably, questions arise concerning the demand-cost appraisals and deliberative powers of the entrepreneur. Manifestly, the rationality, or even the intuitive judgment, required to validate the long-run hypothesis, considering the greater intricacy of the calculations, requires a higher order of acumen than necessary for shorter period maximization. Ironically, full cost doctrines were proffered in part as a simplification, on the grounds that marginal calculations were too complex for the businessman. Now he is required not only to know the present state of the market and costs, but also the future state of each, and the intentions of other firms as well. Mr. Farrell even has him performing matrix algebra on the argument that "our mathematics provides a fairly close analogue to the sort of reasoning that Andrews describes the businessman as performing." (See his "An Application of Activity Analysis to the Theory of the Firm," *Econometrica*, July, 1954, page 297.)

It does not help to ask the businessman whether his price policy is believed to pay best dividends over time. Presumably he thinks so; otherwise an alternative would be embraced. But this is hardly a theory of long-run maximization in any objective sense. It barely transcends the platitude that whatever he thinks is right, he does. It can, of course, be contended that only a subjective, nonmeasurable—even objectively erroneous—theory of price behavior can explain market conduct. But

it becomes a perverse argument when erected to dismantle the concept of excess capacity, for propositions on the latter phenomenon possess, or should have, an objective flavor.

Harrod's argument, in its pricing dimensions, is not so weak operationally—though the implicit diagrammatic appeals often convey a misleading objectivism—for his entrepreneurs calculate price in terms of unit costs at "normal" operations, with profits included. But the very reference to normalcy, together with the "sufficient" profit allotment, and the acknowledgement of the "jiggery-pokery in the fixing of prices" (page 163), disclose the subjective bias in the pricing technique. Equally normal individuals charged with identical responsibilities need hardly emerge with parallel price results. Curiously, after recognizing multiple-product firms, Harrod argues that the firm's own cost calculations describe what other firms will experience in undertaking the same output. This could be so only within some zone of tolerance and hence provides little reason for firms to price merely to cover costs.

Emphasis on the subjective aspects of the pricing process should in any event finally dispel mechanistic ideas based upon fully discernible objective demand and cost criteria. (Current welfare economics often seems to be based on the faulty premise that these are fully objective functions.) Prices ultimately come to be a resultant of the urges and restraints, the moods of caution and abandon, even the neuroticism of entrepreneurs. Efforts to polish it up and purvey it as a piece of objectivity or business rationality and moderation in other than perfect competition and stationary circumstances are illusive—maybe only occasionally true.

On his own terrain, open in all Harrod's discussion is the exact content of the long-run demand curve, or precisely what operational or clock span it serves to cover. (He declares, on page 151, that the long-run demand curve "has greater elasticity than the short-period curve" and consequently the long-period marginal revenue curve "will cut all the cost curves at points farther to the right" than the short-period curve. If Harrod means that the full-demand curve is more elastic at each point, there may be some error unless he visualizes perfectly elastic long-run curves. What he seems to have in mind is the slope rather than the elasticity.) Reference to Marshall does not immobilize criticism, for even in his work the concept is not particularly illuminating. What seems to be fundamental for Harrod is the time projection before competitors will react, not the time length before capital installations can be modified. If entry is suspected as in the immediate offing anyway, perhaps from an existing multiple-product firm and with a presumedly durable market demand division thereafter,

the theoretical pitch may be described as "long-run," but the effective theory of maximization either in operational or clock-moves would belong to the short-run. Cases where potential competitors among existing multiple-product firms express a willingness to produce a substitute product without actually receiving orders belong to the same family of illustrations; there is in these cases no immanent reason for prescribing a long-run expository format.

Failure to work in terms of overt clock intervals constitutes a major shortcoming of Harrod's analysis. Much of the burden of his argument relies on the hypothesis of complementarity between today's price and future demand, with lower prices today lending buoyancy to subsequent demand. Effective resolution of the pricing problem under this hypothesis requires a disclosure of just when "tomorrow" falls in view of discounting, as well as the exact magnitude of the demand complementarity. In neither respect is Harrod enlightening.[6] Some skeptics might even aver some inconsistency in that Harrod utilizes the Oxford studies to buttress the view that price-wise entrepreneurs adopt a "long view," whereas similar studies revealed that their investment purview was remarkably short, for equipment often under five years.[7] A long-run price theory might then be reasonably short clock-wise, suggesting mainly that price is not altered daily or even monthly. Concretely, there may be other good reasons to refute the assigning of any real temporal depth to the long run. For example, if an imminent depression is foreshadowed, with operations unprofitable anyway, it is obviously wiser to make immediate hay. It would be an act of temerity to counsel an entrepreneur to look far ahead. This is not without bearing if we are destined to live in an era of high employment compounded with prospects of depression. Furthermore, so much of Harrod's analysis seems to pertain to a new firm in the drafting-board stage making an initial pricing decision. Yet a child of innovation may well expect the dynamics to continue and not adopt a distant pricing vista.

Finally, Harrod's normalcy pricing criteria are predicated on the efficacy of entry for curbing price and profit distortions. Over a wide area this hypothesis is simply inconsonant with the facts. In the largest of our corporate entities, this may be among the lesser reasons governing price policy. Conversely, granted ease of entry, as in retail trade

[6] Farrell's treatment (*Econometrica*, 1954) is in this respect more helpful. J. R. Hicks, recognizing much the same point, moves to repair the dyke in "The Process of Imperfect Competition," *Oxford Econ. Papers*, February, 1954. It should be noted that Harrod is smitten by the temporal-complementarity case. Yet where quality is judged by price, lowering price toward "full cost" may reduce future demand. See T. Scitovsky, "Ignorance as a Source of Oligopoly Power," AEA *Papers and Proceedings*, May, 1950.

[7] See H. D. Henderson, "The Significance of the Rate of Interest," *Oxford Studies in the Price Mechanism* (Oxford, 1951), pp. 19-20 Also, George Terborgh, *Dynamic Equipment Policy* (McGraw-Hill, 1949), Chap. XII.

where nonpecuniary motives may dominate or in circumstances where large firms are bent on securing a foothold for alternate products, it is an act of valor for the firm to release the trapped profit-bird for the elusive profit-promise.

The theory obtains its best chance for survival in those intermediate cases where entrants are neither doomed nor undeterred. And here, as argued, its heuristic value is doubtful. We are entitled to more illumination on the temporal dimensions of the analysis, on the concept of "normal" operations and its revisions, on the compatibility of subjective and objective demand and cost phenomena,[8] and of the influence of product and technological innovation on price policy. While his fascination is with the "polypoly-entry" case, customary market categories omitted are pure and nonprice competition—though he declares his argument pertinent to the latter (page 159)—oligopoly, bilateral monoply, as well as monopsony and price discrimination structures.[9] Selling outlays, which do belong in a cost-oriented theory, are barely referred to, as if to uphold the laconic tradition of imperfect competition theories. The omissions serve further to narrow the area of materiality of the theory.

In his final point, on the causes of the divergence of actual prices from optimal norms, Harrod concludes that the mischief comes from increasing returns, which makes imperfect competition inevitable. Conversely, without increasing returns there is actual or potential entry and long-period price equilibrium. And: "I further hold that, with constant returns . . . output will normally attain the social optimum" (page 179).

Leaving aside questions concerning the optimum, the argument appears forced. Whether a firm operates in conditions of increasing returns is partly a result of the number of substitute products that rise to sate the diversity of tastes. For goods catering to a large audience, enforced standardization and rationalization might render decreasing costs less likely. But it is the very diversity of tastes which provides opportunities for new entrants, and it is this—the entry—which causes increasing returns rather than, as Harrod sees it, increasing returns

[8] This problem is generally ignored by those who emphasize the subjective nature of demand and cost constructs. I tried some time ago to analyze the problem but there seems to be a vast disinterest amongst price theorists in this question. Cf. my *Price Theory* (Pitman, 1949), Chap. 16.

[9] There is a tantalizing minor paradox here in that Harrod's emphasis on entry presumes an oligopoly aspect while his analysis of the pricing policy is premised on polypoly. Though logically impeccable, it seems more likely that where a firm fears new entrants, it already has close competitors, so that price making does partake an oligopoly character. Cf. M. E. Paul, "Notes on Excess Capacity," *Oxford Econ. Papers*, February, 1954, p. 39. Also Hicks, *op. cit.*, p. 49. Harrod's neglect of the oligopoly problem is noteworthy considering his flirtation with a Cournot solution as early as 1934. See his "Equilibrium of Duopoly," *Essays*.

being instrumental in preventing entry. This is a standard Chamberlin position and it lends credence to his protest that he has been misunderstood by his British friends. (See *The Theory of Monopolistic Competition* [6th ed.; Harvard, 1948], pages 108-109.) Once producers do become numerous, each closeted with a different clientele, then the refrain of too many firms, too many entrepreneurs, each producing too small an output—and thus excess capacity—becomes faintly audible, gaining in volume when the firms are detected operating at outputs below minimum average cost. It follows that the doctrines of excess capacity may hang on, not greatly shaken, much less shattered. In the illustrative form of nonprice competition in which Chamberlin presented it, surely Harrod has failed to dethrone it. (*Ibid.*, pages 193-194.)

Whether with constant returns output will be optimal seems to me doubtful. Apparently Chamberlin's arguments are, in this context, being rejected or ignored. As I accept them, I need only refer to his position. (*Ibid.*, pages 196-199.) Of course, much hinges on the interpretation of "normally" and "optimum." An equilibrium with sales outlays, fewness, nonprice competition, patent grants, and deceptive product variations seems remote from the welfare economist's ideal.

III

In a mood of self-deprecation and recantation, Mrs. Robinson prefaces her article by declaring that her significant volume, which endowed us with much of our market insight and analytical technique, "was a scholastic book" and not "a suitable basis for an analysis of the problems . . . which present themselves in reality" (page 579). Various aspects of the theory of market structures then pass before her pen as she expresses her current attitude.[10] The treatment can be brief, for her work is generally prescriptive and the discussion not exhaustive.

Some opening definitional remarks on industries and markets may be puristically unacceptable. The former is envisioned as consisting of "firms . . . alike in their methods of manufacture," for this "represents the area within which a firm finds it relatively easy to grow," while markets are comprised of "the demand for . . . commodities which are close substitutes" (pages 579-580)—essentially a "group" concept. Then Mrs. Robinson is moved to recommend that we recognize the prominence of the multiple-product firm and the importance of the theory of price discrimination, for while "dropping the fiction of one-commodity firms destroys the simplicity of the analysis of imperfect

[10] Quotations are from her "Imperfect Competition Revisited," *Econ. Jour.*, September, 1953.

competition," it simultaneously "enlarges its scope" (page 580). These are, I think, reforms long overdue to bring our theory closer to industrial facts. They need not render the presentation more abstruse in every case, for the analysis of single-product firms can be retained and applied to multiple-product firms whose outputs are independent on the cost side.

In some blithe paragraphs on "Who Maximises What," Mrs. Robinson sides with the retention of the entrepreneur concept, not as a concrete image but as a personification of a firm in its policy-making aspects. Opinions are likely to differ on descriptive details rather than upon the expository need for the construct.

It was Mrs. Robinson who originally made us face up to what she then called the "fundamental assumption," to be caricatured by some,[11] as pecuniary profit maximization. Appraising the aims of the firm anew, she argues that these are, first, to survive and, secondly, to grow. Both objectives invite a long-run maximization hypothesis. Critics are chided to produce a better premise. On the size of firms, she opines that there is no unique optimal size; some interest, however, attaches to her descriptive comments on growth. Confessing to having been baffled by the oligopoly problem originally, her present paper is disappointing in its failure to devote to it more than the few lines acknowledging her earlier bewilderment.

Reflections on the forms of market competition carry her into the Chamberlin camp, declaring that "the assumption that price is the main vehicle for competition is a great over-simplification of reality" (page 584). She lists the usual types of competitive maneuvers, including differentiation, sales promotion and advertising, price, as well as the legerdermain of raising price to impart a quality aura or snob appeal to a good. All this, detail aside, is already modern doctrine mainly due to the efforts of Professor Chamberlin.

Observing that profit-maximizing calculations are unlifelike, in the most significant section of all, on "Price Policy," Mrs. Robinson argues that in a continuing economy prices are only altered when the reasons are obvious. Her reappraisal of the "marginal revenue equals marginal cost" rule encompasses the following cases: (1) A new product or line for an existing firm: the conception is deemed overformal rather than misleading. (2) A multiple-product firm producing both competitive and noncompetitive products: she concludes that the assumption does not fare too badly. (3) A change in costs: under price leadership and oligopoly the maximization analysis is ineffectual. (4) New products: price policy, she argues, will be contingent upon costs to potential

[11] See T. W. Hutchison, *The Significance and Basic Postulates of Economic Theory* (London, 1938), Chap. IV.

rivals; she refers to Harrod's argument as pertinent. (5) Cyclical fluctuations in demand: competitive and oligopoly prices are distinguished where the latter leads to priorities in lieu of price rises on the upswing, while "full cost" and "spoiling the market" conceptions interfere with adjustments on the downside. Concluding, in a passage to which many of us will subscribe, she remarks that "it seems clearly impossible to replace the old text-book slogans with any simple generalizations. A debate which consists in defending or attacking 'principles,' such as the 'full-cost principle,' the 'marginal principle' or the 'normal cost principle' and trying to fit all types of situations into one system is obviously foredoomed to futility" (page 590).

On the concept of equilibrium, Mrs. Robinson arraigns much of contemporary work, in a manner reminiscent of Marshall, with the plaint that "in my opinion, the greatest weakness of *The Economics of Imperfect Competition* is one which it shares with the class of economic theory to which it belongs—the failure to deal with time" (page 590). Unfortunately she does not move the discussion very far, though she infers that a simple Marshallian hypothesis will not serve, for "there is no such thing as a position of long-run equilibrium which exists independently of the course which the economy is following at a particular date." Irreversibility is pronounced as the rule, for past decisions affect the content of the future equilibrium. This should not have required saying, except that Marshallian long runs appear sometimes to be divorced from the (recent) adaptative path. Mrs. Robinson declares pointedly that "the very notion of long-run supply curve, in its usual simple two-dimensional form, ceases to be admissible" (page 591).

In closing, Mrs. Robinson inquires into the causes of monopoly and declares that "the chief cause . . . is obviously competition," with the vigorous firms absorbing the weaker ones. "Vigorous" remains to be defined, for strength possesses several facets. As a twist on the Galbraith theme, she also renders the judgment that monopoly at one stage of nonintegrated output fosters competition at other stages. "The second main cause of monopoly"—enforcing discipline and loyalty to a price leader—is a "severe decline in demand." And "it is much easier to think of causes for monopoly and examples of monopolies being formed, than it is to think of causes or examples of monopolies breaking down" (page 593). Mrs. Robinson pursues the theme that there are only "narrow areas in the economy where conditions are such that competition can normally prevail" in "The Impossibility of Competition," in *Monopoly and Competition and Their Regulation* (Macmillan & Company, Ltd., 1954), E. H. Chamberlin, editor. Schumpeter's "creative destruction" by new monopolies replacing old ones

and Galbraith's countervailing power seem by accident or design to have eluded her. Her conjecture, however, does deserve more critical attention with empirical investigations providing the clues.

IV

Through Professor Chamberlin's reconsideration runs the strong faith that he has given his intellectual offspring a good constitution, though some mistakes in training are acknowledged. (See "Monopolistic Competition Revisited," *Economica,* November, 1951.)

The vital economic organ—"our economic atom"—is proclaimed to be the firm, with U-shaped cost vertebrae in both the short and the long run. The dissolution of pure competition is attributed to both economies of scale and diversities in tastes which "result in one producer for each product, with often a complicated set of oligopolistic relations between them. This is a far cry from pure competition . . ." (page 349).

Whereas by tradition entry is extolled as in the public interest, Chamberlin writes that this matter "urgently requires comment." Citing patents, trade-marks, colonial trading privileges, and public utilities, he deduces that "from these examples . . . it is not a self-evident principle of public policy to eliminate all such impediments to entry. Indeed they could not be completely eliminated, any more than all men could be made equal in ability or merit by legislation" (page 351). Whetting our appetite, Chamberlin omits a supporting elaborative sustenance.

On his own views, he undertakes to remove "two misinterpretations"; to wit, that " 'tangency' has been associated *only* with the 'group problem' " and the belief that the isolated monopolist "has been held strictly apart from the theory" (page 353). Both views, he alleges, are mistaken. The first error, surely, should never have been committed: a public utility may find profits barely possible only at one rate structure and output: certainly new entry need not be an indispensable prerequisite for the zero-profit result. Likewise the isolated monopolist, interpreted as a firm whose cross-elasticities of demand vis-à-vis other individual firms is small, obviously fits into his analytic scheme though the problems engendered are rather tame compared to the circular structures.

Chamberlin then develops a point on which, in my view, confusion is even more rife, judging from the textbook tradition and teaching practice. He assigns the sloping demand curve for the firm's product to the diversity of tastes. Thereupon, he finds nothing "ideal" about the minimum AC point and its associated output. In his words: "Such a programme [of enlarging output in each firm in order to minimize

average costs] . . . indicates nothing so much as a complete misunderstanding of the problem" (page 354). Manifestly, if the demand for the firm's product cuts AC to the left of its minimum, it would be pointless to compel the production of the minimum AC volume of output. Yet it is not uncommon to find this output level labeled "optimal," as if the concept has meaning isolated from a demand context.

In a more conscious time framework, more might be said on this point. For example, suppose that in the given time interval the maximum profit output was precisely one-half that of the minimum AC output—a hypothesis not too far-fetched to judge by some diagrammatics. If the AC disparity exceeded carrying costs on the stock, it would seem to be prudent for the entrepreneur to produce the larger quantity, doling out in sales (approximately) the monopoly-maximum output in each time period. In the interim—the "idle period"—the firm could devote its facilities to some alternate outputs. Real problems and solutions of this sort are concealed in a stationary framework but become obvious in a time-dress analysis.

Having originally placed the oligopoly problem before us, Chamberlin suggests that "the subject needs to be rewritten in terms of . . . cross-elasticity of demand, rather than in terms of the number of sellers in a market" (page 355).[12] This is likely to be merely definitional, elucidating criteria for the recognition of the problem rather than providing a guide for its resolution. There follows a salutory statement that insofar as a problem signifies "indeterminateness . . . it is certainly the job of the economist as a scientist to say so" (page 355). Some economists have persuaded themselves to the higher virtue of ignoring these situations for the very same reasons, using models of pure competition as their analytic guide. It is not by accident that their policy recommendations often lack relevance.

Discussing cases in which entry into an oligopoly sphere multiplies the number of firms and products and raises unit costs and prices, Chamberlin concludes that this upshot appears to represent "genuine waste" (page 356). More might be said here. Situations can be conjured in which this may occur and yet the product diversity cannot be so simply interpreted. Consider a new product which weans away so many customers from the old products as to drive up their prices. From the paucity of information and the enigmas of interpersonal

[12] In a more recent comment on R. L. Bishop's use of the measure, Chamberlin writes that "Bishop's major contribution . . . is a convincing demonstration of the complexity, even the treachery, of cross-elasticity as a measure of anything." (*Am. Econ. Rev.*, December, 1953, p. 911.) This puts a new complexion on the earlier remarks. Thus: "I . . . hold that the individual seller is isolated under . . . differentiated competition; also under pure competition; and that the essential distinctions are between heterogeneity and homogeneity, isolation and nonisolation" (p. 913).

comparisons, I do not think that we are entitled to conclude that well-being has suffered.

Infringing upon Schumpeter's trade-mark, Chamberlin states that between them "with respect to the role of monopoly in the process of economic development there is agreement." Monopoly stimulates innovation and then the dilemma: to prevent the monopolist from becoming "fat and lazy," there is required "both monopoly and competition . . ."—presumably of the monopolistic variety. This problem, too, I think can only be handled on a dating approach with the life of fixed equipment and the rapidity of technological change constituting the crucial elements.

In summarizing, Chamberlin explains that concepts involving numbers—almost the very language of product differentiation—are to be dropped from the technical vocabulary, to be replaced presumably by a proliferation of cross-elasticities. These austere gestures represent concessions—since withdrawn?—to precision and purity. As they strike a blow at concreteness, my guess is that in verbal accounts they will enjoy a hardy life. There is, too, the remark on entry, that "the problem . . . disappears along with the group, and becomes absorbed into the larger problem of the distribution of resources throughout the entire economic system" (page 362). As it stands, this is obscure and mystifying. Undoubtedly the relations are tangled, as are all general equilibrium matters. Yet there are some peculiar problems of new firms and resource organization under uncertainty which form part of the theory of entry but are not normally treated with the general theory of resource allocation. I see no easy way of excommunicating the theory of entry from particular equilibrium analysis. Perhaps Chamberlin will elaborate his ideas. In the same way it is an exaggeration, undoubtedly harmless, when in his final paragraph he declares that in the new conception "oligopolistic relations . . . [emerge] with greater force, as [do] . . . the full cost principle and other departures from profit maximization, and the relation of the theory to problems of development and growth" (page 362). I doubt that all this occurs merely through quantification of market interdependence via the cross-elasticity of demand. Also, as we have seen, the presumed departures from profit maximization normally constitute only poorly defined long runs substituted for short horizons.

V

Leaving the triopoly which has mixed the heady blends of "imperfect theory" of the past, I should like to turn to the surprisingly uniform doctrines on competition expressed at last year's meetings, written largely from an empirical base. The group already discussed shared,

initially at least, a common belief in real world departures from textbook purity of competition, and a parallel analytic attitude. A recoil from the fascination with monopoly diagrammatics and a new passion for competitive data, for some time inhibited, seems to have been released last year in a concerted move to turn the doctrinal cycle.

In mind, in essence but not detail, are the three papers by G. Warren Nutter, Richard B. Heflebower, and Arnold C. Harberger.[13] A penalty of some injustice to each of them is a price of brevity. However, I do not believe I misrepresent the spirit of their writings.

Last year we were told by Nutter that "it makes sense to say that competition is the normal condition in our economy. Theory should be brought back into touch with the world we live in by recasting monopolistic elements in their proper role: as a special, not the general, case." (AEA *Papers and Proceedings*, May, 1954, page 76.)

On the basis of his longer study he reported that segments of agriculture, mining, and manufacturing, accounting "for perhaps 10 per cent of national income," represented activities in which "competitive behavior . . . is continuous and prompt" (page 75). Industries classified as oligopolistic "account for as much as 35 per cent of national income," divided between those in which pressures of potential competition are strong (15 per cent) and the remainder (20 per cent) constituting "noncompetitive oligopolies." Thus "from these rough estimates, it would seem that about 45 per cent of national income is produced under continuously competitive conditions and an additional 25 per cent under irregularly competitive conditions" (page 76).

Heflebower remarked that "the general tenor of the argument, both as to the variables stressed and much of the empirical evidence referred to incidentally, is to suggest a strong tendency for economic results of industrial markets to be closer to the optimum than one would conclude from much of the literature about this sector of the economy" (*loc. cit.*, page 135). And, he adds: "It seems to me both evident and understandable, once one is versed in the whole of the structure and operations of modern industrial markets, that their operating results approach more closely the ideal than one would surmise to be true from textbook models of oligopoly and monopolistic competition or from the literature on concentration" (pages 138-139).

His opening sentence in the recent volume edited by Chamberlin

[13] I omit the slightly older lecture of G. J. Stigler, "Competition in the United States," in his *Five Lectures on Economic Problems* (London: Longmans, Green, 1949). His view that "competition declined moderately from the Civil War to the end of the nineteenth century, and thereafter increased moderately" (p. 54) was more tentative and less doctrinaire—in this place—despite the statistical scaffolding, than the authors quoted. Omitted also is Clair Wilcox' "On the Alleged Ubiquity of Oligopoly" (AEA *Papers and Proceedings*, May, 1950) in which he concluded that oligopoly was not "the ruling market form in the modern economy," contrary to views expressed by other writers.

reads: "Competition outweighs monopoly by a wide margin in the American economy today." ("Monopoly and Competition in the United States of America," in *Monopoly and Competition and Their Regulation,* 1954.) And though in resource adaptation, profit reduction, and income division, "the situation might be better," still "the economy as a whole, as operating now, reflects the presumed benefits of a competitive market system" (page 111).

Harberger, in an effort "to get some quantitative notion of the allocative and welfare effects of monopoly" (AEA *Papers and Proceedings,* 1954, page 77), confides, after identifying "monopoly power with high rates of profit" (page 84), "that monopoly misallocations entail a welfare loss of no more than a thirteenth of a per cent of the national income. Or, in present values, no more than about $1.40 per capita" (page 85). And: "Adjustment of our results to allow for a maximal distorting effect of advertising expenditures would accordingly make only a slight difference, perhaps raising our estimate of the welfare cost of monopoly in present values to $1.50 per capita, but not significantly higher" (page 86).

Appraising his calulations he feels they "tend to overstate" the "welfare loss due to monopoly misallocations of resources" (page 86) so that "monopoly does not seem to affect aggregate welfare very seriously through its effect on resource allocation" (page 87).

It is difficult to know what Nutter has in mind for the "general" case; surely it cannot be "pure" competition, much less perfect competition. For purity, at the firm's level, did entail adaptations which can hardly be true of industries such as agriculture and mining—often described as "sick" industries—and manufacturing sectors such as textiles. One of the virtues of modern analysis is its ability to cope with all market structures with a highly unified technique rather than exhibiting a predilection for one market arrangement as *the* descriptive form, as Nutter seems to be in danger of doing.

Heflebower goes even further in suggesting the proximity of our present world to the "ideal." Without information on the content of the latter, it is impossible to accept his judgment. What is the ideal output when user-cost calculations are recognized as reflecting a variety of opportunity costs? What is the ideal commodity-chain in an economy in which consumer demands for diversity prevent firms from exhausting decreasing cost opportunities? What is the ideal volume of sales outlays? What is the ideal rate of commodity innovation and product variation? The technological displacement of labor? To raise questions of this sort is to expose our ignorance. Ruefully, most of our welfare economics and optimal pricing propositions belong to a stationary model; the firms which Heflebower observes operate in a

more perturbed world. His assertion that "competition outweighs monopoly by a wide margin" is valid only where both terms remain vaguely defined.

I forbear comment on Harberger's calculations. Further study might lead to a revision of his estimates by another few pennies. Maybe even those who have argued that the economy approximated models of pure competition "in the long run" and "in equilibrium, excluding friction," were astonished at this remarkable statistical confirmation. I fear its statistical riches are too convincing, even embarrassing in providing too much.

In this whole discussion it is hard to resist quoting Chamberlin. Writing on attempts to classify "industries" as being monopolistic or competitive, he remarked that "the practice of classifying such 'industries' as *either* competitive *or* monopolistic . . . seems to me comparable to classifying all members of the human race as either geniuses or idiots." (*Monopoly and Competition and Their Regulation,* page 262.)

I do not propose to challenge the competitive-monopoly allocations of these writers at this place. Nevertheless, the determination that "only 20 per cent" of the income is being produced by noncompetitive oligopolies is not to be construed as signifying that resources are properly allocated in 80 per cent of the economy. There is a structural multiplier at work here; if industry A is classified as noncompetitive, not only are there resource maladjustments in A, but in all its flow-suppliers, and suppliers of suppliers, including the capital goods industries which provide equipment. In the same way, it is in error to argue that because income originating in advertising is only a minuscule part of national income it is unimportant. Without these earnings, many publications, radio stations, programs, etc., would cease; a series of interdependent incomes would topple, to say nothing of a reshuffle in demand. Demand for newsprint and paper, for printing presses, electronic devices, and certain transportation services would seriously dry up. The ultimate upshot would be a multiple of the small percentage of resources devoted to advertising as reflected in national income calculations.

VI

In summary, it seems to me that Harrod has oversimplified the pricing process. A cost-centered theory, long or short, can only be partly valid. Coerced to an arbitrary choice, a short-run maximization hypothesis is not without merit: it is reasonably definite and, considering that recent corporate profit and inventory valuation allowances approximate 25 per cent of current income originating in corporations, it does not seem too wide of the mark. If profits are not being maximized

there is real cause for alarm at the potential exactions from a psychological drift toward a short view.

Mrs. Robinson's recommendation that we work with a multiple-product firm ought to be welcomed. It is a pity that Professor Chamberlin failed to mention it, for it can be a realistic antidote even in the introductory phases of the theory of the firm. It follows that I prize highly the suggestion that the theory of price discrimination be brought to the fore, not as a special case, but one with wide applications of its own; substitute products turned out by multiple-product firms constitute an immediate area of relevancy. Further, in a temporal framework selling often partakes of the nature of discrimination over time, with the theory of inventory and speculation being essentially special cases in the broad genus. In this development the theory of bilateral monopoly also comes more securely into its own, sometimes as a form of discrimination inasmuch as sellers often deal with each buyer singly.

Mrs. Robinson's reference to time, in the clock sense, as well as her derogation of the long run, arouses interest. Yet she has not outlined her ideas adequately and there may be some clash in her espousal of long-run maximization simultaneously with condemnation of long-run analysis. This remains to be cleared up. Personally I should like to see a "dating approach," in the manner of the Swedish contributions, with the production-sales sequence occupying the center of the stage. I once tried to set out some plausible patterns which yielded interesting results, but I alone appear to have been intrigued by them. (See my *Price Theory*, Chapters 17-18.)

Though Professor Chamberlin's championing of the firm as the basic unit is generally accepted, and it ought be the multiple-product firm, fewer will acknowledge the U-shaped AC curve. A unanimous report here is unlikely, at least over the effective output-sales ranges. Notions of entry remain, as he articulately informs us, to be investigated anew, for entry being deleterious to economy on other than industry-fragmentation arguments encounters some natural resistance. Welfare economics may be especially delinquent for its shyness in diagnosing the problems created by entrepreneurial product variation.

Above all, the examination of monopoly in the dynamic milieu is sadly incomplete. Chamberlin's remarks are too brief and though we do have the ideas of Schumpeter, more remains to be said. Otherwise there is the danger of being swamped by the opinion of practical men that monopoly alone insures progress.[14] As a historical proposition, in an age of research staffs, something may be said for it, though it is

[14] See P. Hennipman, "Monopoly: Impediment or Stimulus to Economic Progress?" in *Monopoly and Competition and Their Regulation*, for some review of the literature

not a distillation that springs from careful research, for breaches in the fence of advance can be assigned to the same cause.

All seem to agree—though perhaps not Harrod—that the tangency solution is not vital to the analysis. As anything other than an *ex post* addition of profit magnitudes, or a special case, this is a relic of a faith in an ultimate stationary repose. Here again we tread on the conflict of long- and short-run analysis. Proponents have probably already chosen up sides.

Surprisingly, there has been no mention in these "revisits" of the role of funds and money markets as a possible limitational factor on the firm's activities and production decisions, despite the participation of two such gifted macroeconomic expositors as Mrs. Robinson and Mr. Harrod in the debate. It must always seem puzzling that the entrepreneur is conceived as maximizing profits, which entails access to loan funds, and yet problems of borrowing, of loan credit, and capital rationing are rarely mentioned in price-production analyses. Despite disclaimers, apparently we really do visualize unlimited credit or barter modes of compensation to factor-owners.

All three, it seems to me, despite recognition and reference, still place inadequate emphasis upon the subjective aspects of the pricing and production process.[15] Usually—and this is true of most of the literature—either subjective or objective demand-cost schedules are recognized, but not both. Harrod's concepts turn out to be pieces of subjectivism. Objective facts should somewhere enter the scheme and the compatibility of the two ought be demonstrated.

[15] Compared, say, to the cogent emphasis of F. Machlup, *Economics of Sellers' Competition* (Johns Hopkins, 1952), Chap 2.

DISCUSSION

Fritz Machlup: We have been assured lately that we do not have to be afraid of monopoly in this country. Specifically, we have been told: that competition is the general case and the normal condition and its performance is not far from the ideal pictured in the old theories; that we have enjoyed a fine rate of technological progress thanks chiefly to our monopolies financing research and innovation; that thanks to big business or monopoly we enjoy a larger scope for freedom of choice and can satisfy a greater diversity of tastes; that bilateral monopoly is a blessing taking the curse off most of the unilateral monopoly that has sprung up; and that whatever monopoly we have costs us only $1.50 a person per year. Thus, we can rest assured and forget our persecution complex, and perhaps also our prosecution zeal against suspected antitrust law violators.

The two speakers in today's session do not share such views; they seem to take the social cost of monopoly, the danger of reduced competition, and the advantages of vigorous competition much more seriously. Professor Clark tentatively lists "public policy expressed in the antitrust laws" among necessary conditions of vigorous competition and he seems to advocate that collusion be checked and the competitively-minded individualist be protected. He does not accept the view that countervailing power is as good as competition, he objects that a major part of competitive behavior—bargaining with all your might—was "annexed" as a phase of countervailing power, and he states that under bilateral monopoly "almost anything might happen."

Professor Weintraub does not accept the view "that monopoly alone insures progress." And although Professor Clark mentions that "atomistic industries" would lack the funds as well as the incentive to undertake heavy research programs, he emphasizes the function of competition in the diffusion of the benefits of progress—in re-creating incentives for new ventures after eroding the profits from the previous ones. His remark that incentives to innovation could not exist "if the diffusion were instantaneous and complete" is probably intended to convey his opinion that the innovator's head start would be insufficient if imitators were not delayed by some institutional barriers such as the patent system. But how long a delay would be appropriate to achieve optimum rates of innovation and of diffusion of benefits? As I have stated in my *Economics of Sellers' Competition* (1952):

> To buy innovation by paying with unnecessarily long delays of imitation is a poor bargain for society to make. Imitation always and necessarily lags behind innovation. It will be the best deal from the point of view of society if innovators optimistically overestimate this lag. If they expect the lag to be longer than it actually is, innovation will be enhanced and imitation will not be delayed. That it may create this socially wholesome illusion on the part of innovators is the strongest justification for a well-designed patent system. (Page 556.)

The worst bargain for society would be patent laws or other monopolistic barriers which protect the innovator better than he thinks they do. For this would delay imitation without stimulating innovation accordingly. While Clark does not discuss this problem, his comments on the need for the erosion of

profits by competition and their re-creation through further innovation indicate to me that he might accept my way of thinking on these issues.

Weintraub is critical of the views of the all-is-well economists. He does not examine the cost-accounting methods behind the surprisingly low estimate of the welfare cost of monopoly, but he reminds us of the fact that Harberger identified monopoly power with high rates of profit. Many writers on the subject have insisted that monopoly is reflected less in increased profit rates than in increased or inflated costs. A monopolist may pay more than the competitive price for productive services; he may use them inefficiently; he may have transformed his monopoly rents into money expenses; he may have capitalized them, inflating the base on which his rate of return is calculated. (See my *Political Economy of Monopoly* [Johns Hopkins Press, 1952], pages 490-497.)

High production cost behind monopolistic barriers, such as tariffs, patents, building codes; high depletion cost in mineral monopolies; high management cost and high labor cost in enterprises sharing their profits with management and with their labor force—these are some of the economic consequences of monopoly excluded from Harberger's estimate of its welfare cost.

Not in such political or evaluative implications, however, but rather in their theoretical contributions lies the chief value of Clark's and Weintraub's papers. Weintraub's survey of what Harrod, Joan Robinson, and Chamberlin had to say when they revisited their earlier explorations is highly suggestive. Clark's "dynamic criteria of appraisal" of the goals and performance of competition is a piece of theorizing distinguished by a rare combination of analytical technique and mature wisdom.

The call for dynamic, more dynamic, and fully dynamic theory is repeated over and over again. I fear that the dynamics of the meaning of the word "dynamic" is too great for the term to be of continued usefulness if we want to communicate and not only to orate. Clark wants to communicate, I know, and therefore I take the liberty of commenting a bit on his choice of language.

He speaks of a gap between theories of equilibrium and theories of growth and development. As I see it, equilibrium is a tool of thinking needed to explain change, no matter whether it is change in market prices or in business investment or in employment or in the rate of growth. Equilibrium is a valuable concept both in models which disregard time lags—static theory—and in models which present sequences in time—dynamic theory. Since a theory of growth will ordinarily use the equilibrium concept, there can be no contrast between theories of equilibrium and of growth. What Clark meant, I suppose, was the contrast between "static theories of price and output" and "theories of growth and development."

Price theory itself may be static or dynamic. I once gave a graphic description of a "dynamic or time-sequence analysis of effects of a selling campaign," in which five different outcomes—different sales volumes at one price and different prices for one sales volume—were shown to result from a given selling effort, depending on the chosen sequence of actions and on the time intervals between the steps. The five points would all coincide if sequences and intervals of time did not matter and demand curves were assumed to be reversible

(*Economics of Sellers' Competition*, pages 185-189). Whether the complicated dynamic model has to be used or the simple static model will do, depends on the kind of problem at hand; that is, not on whether sales actually depend on the time sequences and intervals but on whether the differences really matter for the kind of answer required. Clark gave a very similar description but did not say whether he believes that the dynamic model is always superior. If he thinks so, I would disagree. Dynamic theory is better only where it is needed; where the analytic job can be done with the simpler, less realistic, static theory, the latter is preferable.

"Fully dynamic theory," Clark says, "must accept indeterminateness." I suppose he means to suggest this as a definition; namely, that a theory which is both dynamic and indeterminate should be called "fully dynamic." I do not know whether this would be helpful. Oligopoly theory, to be sure, will usually have to be dynamic, will have to make large allowance for uncertainty in the anticipations of sellers, and will have to leave a large scope for indeterminateness. (See my chapter on "Oligopolistic Indeterminacy," *op. cit.*, pages 414 ff.) I should prefer to use language which does not mix the dynamic elements, the uncertainty elements, and the indeterminateness, since all these are different things that ought to have separate names.

There is no disagreement of substance between Clark and myself on the dynamics of oligopolistic competition. I find his emphasis on the time interval between move and countermove as a key element in the theory of oligopolistic competition most appropriate and significant.

The tangency theorem comes in for a good deal of criticism, and in at least one respect Clark's objection coincides with Harrod's, reproduced by Weintraub: businessmen are not so shortsighted as to overlook potential competition; hence they may ward it off and secure larger sales volumes by charging lower prices. I believe that the proponents of the tangency theorem had only the case of a polypolistic seller in mind, who would regard himself as too small to arouse any responses on the part of competitors, old or new. The theorem was not meant to apply to the case of oligopolistic competition under the pressure of new entry, actual or potential.

Clark's remark on product differentiation as a competitive device confirms my own conclusions that quality competition can be quite vigorous and that product differentiation may weaken but will often invigorate competition. I also showed that product standardization may be an aid to price competition, but is often an aid to price maintenance and other forms of collusion (*ibid.*, pages 163-168). But may I take exception to the way in which Clark put his comment? He said that "theory appears to regard product differentiation as always a shelter from the rigors of competition." My theory, for one, does not. Clark obviously meant "some theorists." After all, no theorist is appointed or ordained to speak in the name of "theory."

Twice in his written paper Weintraub made bitter or disconsolate remarks about the fact that his fellow economists have sadly neglected certain important points he had made in his book on *Price Theory*. I know exactly how he feels. When I first read Clark's paper, at eight different points I cried out: "Oh

why has he not read my book! ! !" Well, I suppose, there just is not enough time to read all we want to read.

And perhaps I may turn the tables on Professor Weintraub and ask him whether he has read what Milton Friedman recently wrote about that funny ambition of some social scientists to verify the fundamental assumptions of a theory instead of the conclusions deduced from them? I am asking this apropos Weintraub's remarks about "operational testing" of the assumption of profit maximization. After complaining about the impossibility of the assumption of long-run profit maximization, he says: "Of course, it may be alleged that businessmen seek to maximize their long-run profits, not that they succeed. This is a very different theory indeed." It "is hardly a theory of long-run maximization in any objective sense. It barely transcends the platitude that whatever he thinks is right, he does." I cannot resist quoting the answer which I gave to this a few years ago:

> My emphasis on this methodological "subjectivism" has been widely criticized. One of my critics believes that "refuge in subjective interpretations of the cost and revenue functions . . leaves theory saying that businessmen do what they do because they do it." (R. A. Gordon, . . . AER, 1948) This is a misunderstanding The businessman in the model acting upon marginal principles will react, say, to an increase in the price of fuel oil, not just by doing anything that may come to his mind, but by making some "typical" adjustments in his production, input, output, and prices. The point is that, in order to predict or explain the type of adjustment, we do not have to know the subjective whims and guesses that may have influenced his initial position. For, happily, the direction of the "equilibrating" (adjusting) action is to a large extent independent of the exact position of "equilibrium" from which we assume the businessman has been pushed by the "disequilibrating" change. (*Ibid*., page 36)

I propose a pact to Weintraub: that we shall read each other's books and discuss our disagreements.

KERMIT GORDON: If I sense correctly the tone of Mr. Weintraub's paper, he is disturbed by what he regards as the immoderate character of the current wave of revisionism in both the theory of markets and in the appraisal of market behavior in the American economy. I share his uneasiness.

The pendulum was bound to swing, and a swing in the present direction was, I think, salutary. Abuses were unquestionably committed in the name of the new theories of competition which were unveiled in 1933. Illustrative firm demand curves were sometimes drawn with a slope such as to suggest that in group equilibrium the scale of the firm would be comparable to that of an itinerant peanut stand. The assumption of short-run profit maximization was accepted much too uncritically. There was attributed to entrepreneurs a precision of knowledge with respect to their cost and demand functions which they obviously do not possess; witness Mrs. Robinson's recent acknowledgement, by way of expiation, that the firm's demand curve "is a mere smudge, to which it is vain to attribute elegant geometrical properties." The concept of the "group" or "industry" was taken much too literally, with the result that the analysis of substitutability relations was unduly circumscribed. And, of course, the whole analysis suffered from being conducted in a static framework.

But all of these matters are commonplace and have been for some time now.

What concerns me—and I think Mr. Weintraub—is the sense that the wave of revisionism has developed a momentum which threatens to carry it into some salients which cannot be held. There is even the possibility that some of the current themes may be mutually inconsistent. Two of these themes, for example, may be linked in the following curious proposition: the pervasiveness of monopoly power in our economic system has been favorable to a rapid rate of technological progress, and anyway, there is very little monopoly power in our system. I would not hold that the two parts of this proposition are necessarily irreconcilable, but I would maintain that those who assert both parts to be true have some explaining to do.

Mr. Weintraub examines at considerable length the views expounded by Mr. Harrod in his recent essay, "Theory of Imperfect Competition Revised." A reading of this essay leads me to ask, I suspect with Mr. Weintraub's approval, "Are these revisions necessary?"

Mr. Harrod would like to erect in the very center of price theory the concept of limit pricing to deter entry. In his view, entrepreneurs may be counted on to set prices at levels sufficiently below those indicated by the geometry of short-run profit maximization to render their markets unattractive to potential rivals. This principle leads Mr. Harrod to discard the doctrine of excess capacity and enables him to demonstrate the compatibility in certain circumstances of full-cost pricing with marginalism.

There is, of course, nothing very new or startling about the proposition that limit pricing is a fairly common phenomenon; it may be found in the textbooks. Serious doubts are raised, however, by two facets of Mr. Harrod's analysis: the apparent assumption that the full exploitation of short-run profit opportunities will, by attracting entry, generally entail the sacrifice of a greater sum of discounted future earnings, and the view, implicit rather than explicit, that limit pricing is typically employed for the purpose of deterring entry.

Mr. Weintraub has discussed the first of these points at some length, and I would associate myself with his misgivings. However misleading it may have been to imply that entrepreneurs typically act on the maxim, "Gather ye rosebuds while ye may," there are nevertheless important questions to be asked about Mr. Harrod's presumed substitute, "A stitch in time saves nine." One would want to know a good deal more about how many stitches are in fact saved by a stitch in time (it puts no strain on the imagination to think of cases in which nine stitches in time might conceivably save one); about the distribution over time of the stitches saved; and about the rate of time preference applicable to these stitches.

Mr. Harrod rests his case for limit pricing in part on the proposition that "the uncertainties of the future have a tendency to restrain the monopolist from raising his price much above a competitive level, even if all known factors indicate that he could do so with safety." But doubts arise if we look for the causes of this uncertainty. It would be popular current doctrine to hold that entrepreneurial uncertainty about the future arises in large part from fear of the "kind of competition which counts"—in Schumpeter's words—"the competition from the new commodity, the new technology, the new source of supply,

the new type of organization . . . competition which commands a decisive cost or quality advantage and which strikes not at the margins of the profits and the outputs of the existing firms but at their foundations and their very lives." But does this kind of anxiety foster limit pricing? Will the voluntary narrowing of profit margins fend off this kind of competition? Would moderation and restraint in the pricing of ice have stopped the electric refrigerator? I think not, and I would suggest the odd hypothesis that the perennial-gale doctrine is at least as easy to reconcile with a relatively short-run theory of profit maximization as with a long-run theory.

The second basic reservation I have about Mr. Harrod's analysis is the feeling that the motives for limit pricing are much more complex than he suggests. On the basis only of the most casual and unsystematic observation, I would hazard the guess that the conscious design to discourage entry is present only in a small proportion of those cases in which limit pricing occurs. One thinks immediately of the concentrated sector of American manufacturing industry in the two or three years following 1945. Limit pricing was widespread, but in many of these industries any serious fear of entry which may have existed could have had no firmer basis than neurotic anxiety. The automobile industry, by holding prices below the short-run equilibrium level, created an army of frustrated potential buyers. Yet if the automobile manufacturers had really been seriously concerned about the possibility of entry, which I doubt, they might have been better advised to raise prices to the equilibrium level for the purpose of eliminating the waiting lists; for these waiting lists, one might argue, were a clearer and more unmistakably inviting signal to potential entrants than very high profits would have been.

Mr. Chamberlin is, of course, not to be grouped with the ardent revisionists: it may be noted that the title of his essay uses the word revisited, not revised. I find little to quarrel with, either in Mr. Chamberlin's exposition of his present views or in Mr. Weintraub's summary of Mr. Chamberlin's position. I am a little sorry, however, that in the interest of theoretical purity and analytical elegance, Mr. Chamberlin has decided to part company with the concept of the group. Indeed, in another place, he deals even more harshly with the related but looser concepts of industry and community, castigating them as a snare and a delusion.

The argument here is a familiar one, and few would be disposed, given the usual premises, to question the pure logic of Mr. Chamberlin's position. It has been clear—at least since Mr. Triffin's book—that these group concepts are treacherous, tending to conceal variations in substitutability relations within the group and the existence of substitutability relations across group boundaries. The dangers, moreover, are not merely presumptive. Most of us have run across empirical work in which these group concepts have in fact "snared and deluded" the authors. And one can sympathize with Mr. Chamberlin's exasperation when someone draws inferences with respect to the size of the price-marginal cost gap from a calculation of the concentration ratio for the cast-iron lawn dog industry. In defense of the group concept, however, I am moved to say that anyone who could commit such a crime would, in the absence of the group concept, do something else just as foolish.

It would be a mistake, I think, to blink the fact that industries do exist; they were not just thought up by economists. They are institutionalized in thousands of national trade associations. Firms view themselves as members of industries. They do not in fact think of themselves as cast upon a sea of cross-elasticities which extends in every direction as far as the eye can reach.

It might be objected that these are institutional considerations which have no place in a discussion of pure theory. I would suggest, however, that the viability and growth of the trade association and the apparent strengthening of the firm's identification with the industry tend to lend plausibility to the hypothesis that these arbitrary industry boundaries do in many cases correspond roughly to significant breaks in the chain of substitutes. If this were not so, it would be hard to explain why trade associations, given their usual objectives, have fared so well.

More important, however, is the proposition that the identification of the firm with the industry causes the firm to behave differently than it otherwise would. Trade associations play an important role in the process of price and output determination; and the institutional framework to which he is attached conditions and modifies the businessman's perception of cross-elasticity relations. If the industry concept tended only to narrow the economist's view of the ramifications of competitive relations, there would be no loss in abandoning it; but if it tends also to narrow the businessman's view, as I suspect it may, then it would be a mistake to banish the group concepts from the halls of price theory.

Lest I be accused of a temperamental affinity for the *status quo*, I want to call attention briefly to at least one aspect of monopolistic competition theory which seems to me in need of revision. The argument is not a new one—the essential point having been made in 1918 by J. M. Clark and a few years later by Frank Knight—but it has been overlooked or rejected in the development of the new theories of competition. It relates to the treatment by Chamberlin and others of the selling cost problem. Most economists have followed Chamberlin in drawing a sharp distinction between selling costs and production costs. In Chamberlin's words, ". . . of all the costs incurred in the manufacture and sale of a given product, those which alter the demand curve for it are selling costs, and those which do not are costs of production . . . those made to adapt the product to the demand are costs of production; those made to adapt the demand to the product are costs of selling."

This distinction will not, I think, stand critical analysis. It would seem to be based on the questionable premise that the concept of product embraces only those material qualities which would commend themselves to an industrial purchasing agent or a home economist. Hence the notion that only production costs can alter the product. Yet on the other hand we are told that the test for homogeneity or heterogeneity of product is a psychological, not a material, test—the test of buyer indifference. This doctrine would suggest that products can be altered by producer activity which does not in any way affect the material qualities of the good; i.e., selling costs.

Economists have been reluctant to accept, or at least to incorporate into their economic thinking, what every good advertising agent knows to be

true: that in an opulent society such as ours, consumers are frequently more attracted by the sizzle than by the steak. Consumption decisions are often determined by the talismanic attributes of goods rather than by the objective qualities which fit more neatly into the rationalistic tradition of economics. Opulence surrounds the basic physical wants with a host of social wants which people try to satisfy through the consumption of goods. And the clear evidence of consumer behavior would suggest that the talismanic attributes of goods—the creation of which is one of the main objectives of modern advertising—are regarded by buyers as capable of satisfying these acutely-felt social wants.

If this view is correct, the commonly accepted sharp distinction between production and selling costs would appear to be untenable. What, after all, is the difference in principle between the type of cost entailed in lengthening the hood of a Cadillac, in order that greater prestige shall attach to the ownership of a Cadillac, and the printing of an advertisment showing a Cadillac standing in front of a country club, in order that greater prestige shall attach to the ownership of a Cadillac? And yet it is the custom of economics to regard the one as altering the product and the other as altering demand—the custom, even, of the less cautious among us to categorize the former as progress and the latter as waste.

Inconsistencies such as this suggest that we might well abandon the sharp cleavage between production and selling costs in favor of a view of the matter which is compatible with the subtle and evanescent character of consumer wants in an opulent society.

GARDNER ACKLEY: I must begin by saying that there is little in Professor Clark's paper with which I find myself able to disagree. As is always the case with whatever subject Professor Clark touches, the result is illumination and stimulation.

There were a few minor points out of the number he makes with which I might have picked an argument; but even these turned out, when I attempted to develop them, to become largely issues of semantics. I have decided, therefore, to use my few minutes for what might be considered a methodological matter. It relates to Professor Clark's fundamental thesis that our theories of competition, to be realistic and to be useful in policy, must be made dynamic.

I expect that there can be no disagreement—indeed it is a commonplace—that our economic theories need to be dynamic. The trouble is that the word dynamic does not always have a very clear or specific meaning. As someone has remarked, dynamic is merely an adjective which distinguishes one's own theories from everyone else's.

I wonder, therefore, if it would not be useful to specify rather clearly what we may mean by a dynamic theory of competition before we proceed to construct or to criticise one. I may say in advance that it is my feeling that Professor Clark has not given a very clear or consistent meaning to dynamic theory and that this may be responsible for my impression that his paper represents mainly a series of somewhat disconnected observations. I find many of these observations individually very penetrating and stimulating; but

nevertheless the thread which ties them together is sometimes hard to find.

Just what is the distinction that Professor Clark means to imply in his contrast of "static models and dynamic aspects"? In the very first sentence of his paper reference is made to "the gap between theories of cost-price equilibrium and theories of production, growth, and development." Only a few sentences later we have it that dynamic theories "include the tendencies toward equilibrium. But because these tendencies never reach their static limits, dynamic theory cannot use any features which are needed only to enable a model to attain this impossibly precise completeness. . . ." Still later we read that "a theory of competition as dynamic process must be not a model but a framework within which many models may find their places, including equilibrium models as limiting hypothetical cases." This is about all that I find which refers explicitly to this contrast of static versus dynamic theories. There is, however, also an implied definition of dynamic in the substantive matters and problems which Professor Clark chooses to discuss.

Leaving aside for the moment Clark's particular meaning, what meanings might we give in general to this contrast of static with dynamic?

I assume that we agree quite generally that static refers to an analysis of states or conditions of equilibrium. Given the values of certain outside or exogenous factors, there is (or may be) one pattern of the internal or endogenous variables from which all tendencies to further change would be absent. This pattern represents an equilibrium situation.

Now, because equilibrium is a situation from which change is, by definition, absent, equilibrium theory has frequently fallen into the trap of eliminating from consideration those things which are the inevitable concomitant of change—most of all, uncertainty. If equilibrium is a prediction—a state which will someday be reached—then this is legitimate. But if, as I assume it usually is, it is only an analytical device, then there is no excuse for eliminating from the description of behavior the effects of change and uncertainty. To put these back into static theory, then, is a first step toward making theory dynamic.

Some of Clark's dynamics consist precisely of this. It seems to me that much of what he has to say about the content of long-run and short-run cost curves and about Chamberlin's tangency theorem is merely an improvement of the static analysis by the recognition of the effects of change and of the uncertainty which change generates.

To introduce the effect of change and uncertainty into our demand and supply curves is an important step. But it is still not part of what I would consider a true dynamics: an analysis in which the concern is with processes of change. Nor does Professor Clark stop with this first step.

As we have come increasingly to realize, in order even to define the existence of a stable equilibrium, we need at least some rudimentary dynamics. These have always been implied in all of our equilibrium models, but they have often been inadequately explored. The question is: How do sellers (buyers, factor suppliers, et cetera) behave when equilibrium does not exist? What precisely is the nature and the time sequence of their behavior? How do they respond, and when? Only by investigating these questions can we be sure that an

equilibrium, or at least a stable equilibrium, exists. And the properties of the equilibrium depend on the nature of the disequilibrium behavior.

A great deal of the substance of what is now called "dynamic analysis" is merely an explicit exploration of the way in which equilibrium is approached. A comparative statics analysis concentrates on previous and the new equilibrium positions and ignores the process of change from one to the other. A dynamic analysis shows the time sequence and pattern of movement between the two equilibrium positions.

This type of dynamics may also recognize that full equilibrium is rarely or never achieved. Changes in the exogenous variables may be so rapid and so extensive that the system never reaches one equilibrium before that equilibrium is replaced by another. As a well-known text once put it, the dog continues to chase the rabbit (equilibrium), but the position of the rabbit continually changes. To understand the behavior of the dog we need to know where the rabbit (equilibrum) is at any time, even though we know that the dog will never catch him.

What would be the content of the analysis of competition which corresponds to this rather narrow concept of dynamics? It would deal, I think, with several of the questions that Professor Clark discusses. When he talks of the process of profit erosion, and its duration, he is, it seems to me, discussing the dynamics of the approach to equilibrium. Technological change or other disturbances to equilibrium occur. What is the sequence of events by which the market adjusts—through innovation, imitation, and competitive response to this initial change?

This, too, is important and useful. And it requires explicit recognition, as Clark urges is necessary, of the time lags in the process of market adjustment.

But there is another and broader content to economic dynamics—the content which Clark suggests when he contrasts theories of equilibrium with theories of growth and development and which he deals with several times in the substance of his paper. The narrower dynamics retains an essential tie to statics; it merely investigates more explicitly the processes involved in "tendencies toward equilibrium." But the broader type breaks more fundamentally with the equilibrium concept. In the broader dynamic analysis, movements of variables represent not merely the working out of tendencies toward equilibrium. Rather, processes of change are seen at least in part to be irreversible, self-generative, and self-determining. Change is a product of previous change, as well as of other current variables. Partly, this is a matter of bringing into the analysis, as endogenous variables, factors which the equilibrium analysis took as exogenous. Thus we would attempt to explain, at least in part, such things as the state of technology, the number of sellers, the evolution of buyers' tastes, the nature of the market institutions (such as the form of price quotation and methods of sale), the attitudes of sellers toward their rivals' moves, their long-run versus short-run horizons, et cetera. These would be things to be explained rather than to be assumed.

But the broader dynamics to which I refer does more than merely to enlarge the list of variables. It also, as I have indicated, considers the factors responsible, not only for the levels, but for the rates of change of these

variables. When Professor Clark sets up his criteria for appraisal of market performance, he is clearly thinking very specifically in these terms. He is concerned with whether a particular market situation is productive of a more or less rapid rate of introduction of new processes and new products, with the nature and speed of product evolution, and with the speed of the creation as well as the erosion of profit opportunities. And he has some very interesting things to say about these.

All of these contributions toward a more dynamic theory are important and useful. But if we are trying to provide a general framework for a dynamic theory of competition, we probably need to recognize more explicity than I think Professor Clark has done that dynamic can have several meanings. And I believe that we must develop somewhat separately the appropriate theoretical tools as well as the substantive content of these several levels of analysis. As is the case with other branches of economic theory, the dynamic analysis of competition and markets is still in the stage of foundation laying.

Professor Clark has given us some sketches of a few elevations of the structure. But it is still a little early to tell what the building will look like when it is completed.

THE IMPACT OF ANTITRUST LAWS

VERTICAL DISINTEGRATION IN THE MOTION PICTURE INDUSTRY

By SIMON N. WHITNEY
New York University

In July, 1938, the Department of Justice filed its antitrust action, *U.S.* v. ***Paramount Pictures***, in the Federal District Court of New York, and in May, 1948, the Supreme Court, speaking through Justice Douglas, affirmed the government's hard-won victory. The five so-called "majors"—Loew's, Paramount, Twentieth Century-Fox, RKO Pictures, and Warner Brothers—were ordered to dispose of their theatrical holdings, and they and the three non-theater owning defendants—Columbia Pictures, Universal Pictures, and United Artists—were enjoined from certain monopolistic or discriminatory practices. One of these was renting films to theatrical circuits on a circuit-wide basis, to the disadvantage of competing independent theaters. Another was "block booking," or conditioning the offer of one film on the purchase of another, often (prior to 1940) by licensing the coming year's product in one transaction. The eight companies must now, therefore, rent their films "theater by theater," and, except where a noncompeting theater negotiates for several at once for convenience, "picture by picture." This is important, because the eight not only produce most of the domestic features but distribute—that is, negotiate the rental to exhibitors (theater owners)—some imports and many domestic features produced by independents.

The government convinced all eleven sitting judges of the District and Supreme Courts that the defendents had conspired to restrain trade and monopolize. Although the five majors had full or part ownership of only one-sixth of the 18,000 theaters, so many were first-run houses in big cities that they took in a much larger percentage of all box office receipts. Not only did all eight defendants' features usually appear first in these affiliated theaters but the majors had sometimes used their control over the film supply to force independent exhibitors to sell out to them or accept partnership arrangements. The remaining independents were in general relegated to "subsequent runs," behind a "clearance" of some stipulated number of days after the close of the next prior run.

These were some of the conditions that the government and the courts hoped to cure by divorcing theaters from the producing and distributing branches of the industry and by prohibiting such practices as block booking. Between 1948 and 1954 the integrated companies

were successively split by five consent decrees into two parts each, creating five disaffiliated theater circuits—which, in turn, were allowed a period of time to sell a quarter to a half of their theaters. Although many cynics suspect that these corporate pairs continue under common control, the evidence is that they deal with each other at arm's length.

The Paramount decrees represent the most important experiment in vertical disintegration under the Sherman Act—one of greater potential significance than the separation of anthracite mines and railroads ordered in 1920 or of Pullman car operation and manufacture ordered in 1944. I shall treat separately the effects on (1) exhibitors, (2) independent producers, (3) the defendants themselves, and (4) the public.

The aim of the whole case was to win for exhibitors protection against being forced to sell out if their location and policies proved profitable, against being forced automatically into subsequent runs behind long clearances, and against being forced to accept bad films as the price of getting good ones. The first two aims were also those of the "circuit" decisions, *U.S.* v. *Griffith* and *Schine Chain Theaters* v. *U.S.*, which Justice Douglas announced on the same day in 1948 and in which the Supreme Court found that the large, although nonaffiliated, circuits had been using their buying power to gain unfair advantages over smaller theaters.

These aims have been realized. If, for example, an exhibitor thinks he can prove that the location, size, or other characteristics of his theater deserve an earlier run, there are lawyers who will help him, on a contingent basis, to sue the eight companies under the treble damage provision of the Sherman Act. What Justice Douglas called their "marked proclivity for unlawful conduct" will be prima facie evidence on his behalf, and, under the precedent of the Jackson Park case (*Bigelow* v. *RKO*), decided by the Supreme Court in 1946, his damages may be estimated liberally. The producer-distributors, under this threat and the courts' 1948 injunction against discrimination, and because they have no reason now to favor their formerly affiliated circuits, are apparently granting "availabilities" to theaters equitably. The motion picture decrees, in the light of their aims, can be classed as highly successful.

The first qualification appears when we ask how many exhibitors have been helped in practice. Since an injunction to discontinue their theater expansion programs had been issued against the majors in 1940 as part of an earlier consent decree (which the government decided in 1943 to abandon), divorce may not have been necessary to save many independent exhibitors from being bought out. There are no figures

as to the number of theaters which have advanced their runs, but a questionnaire of my own, sent to 221 exhibitors and answered by 41, disclosed that only three of these had stepped up. Of my 41, 12 noted a shortening of the clearance after the first run in their towns, the average change being from fifty-six to thirty-three days. In the remaining towns, this clearance had averaged only twenty-three days and is unchanged. Apparently, and fortunately, it is the unreasonably long clearances which have been reduced.

The mere fact that only a minority of theaters had received a practical gain would not explain why this successful decree is so unpopular. Criticism of the outcome is a regular refrain in the opinion columns of the several trade magazines read by exhibitors. The Department of Justice has received more complaints against the decree than against any other in history. The Senate Small Business Committee held extensive and inconclusive hearings on it in 1953. The Theater Owners of America, the largest trade association of exhibitors, demands that the Department of Justice drop its veto on vertical integration. This change in attitude calls for explanation.

First, the decree is blamed for the "product shortage," or reduced flow of feature pictures. The big decline has come in 1954, in which the number of domestic features released by the "national distributors," or members of Eric Johnston's Motion Picture Association of America, has declined by more than 20 per cent. The case of RKO, which never got into full swing again after it had shut down its studios for a period in order to "root out Communists," is extreme; but the major studios generally have reduced their output, and smaller studios have turned predominantly to manufacturing grade B's for television. The theaters have had to fill their screen time with independent and foreign films and reissues and by giving some features a longer playing time.

The majors explain their part in the product shortage very simply: they have found that, when pictures are only moderately better than those on television, people stay home. Their deliberate policy, therefore, is one of better pictures, even if the higher cost per picture reduces the number made. But divorcement has played its role. Formerly a big company would release a feature a week, one aim being to keep the screen time of its affiliated theaters occupied. Now this motive is gone. Moreover, with block booking abolished, the producer can no longer count on renting a year's output, good and bad alike, ahead of time; he must make sure that each picture is salable on its own merits; and this suggests more attention to each one made and less scattering of efforts.

The exhibitors view the reduction in output as a conspiracy to raise

prices by reducing supply. The Allied States Association—second largest exhibitor organization—has considered the possibility of investing in the stocks of motion picture producers and then voting for directors who would increase production schedules. The Theater Owners of America endorses the proposal of National Theaters, the former Fox circuit, to go into picture making (which the Department of Justice has vetoed) and plans to raise 10 million dollars to finance independent producers. The very reason which stimulated William Fox to originate moving picture integration in 1910 in his battle against the Motion Picture Patents Company, the trust of that day, and which inspired the First National Circuit in 1917 to build studios in its fight against Paramount-Famous Players-Lasky Corporation, the trust of *that* day, is at work again: to assure a supply of the raw material. This is the same motive that causes oil refiners to go into crude production and steel mills to search for iron ore.

A really bitter complaint of exhibitors is against the rise in rental terms, which both distributors and exhibitors agree has occurred. A poll of theaters conducted for COMPO (the Council of Motion Picture Organizations, which represents producers, distributors, and exhibitors) disclosed that in 1946 they paid an average of 31 per cent of their box office receipts as film rental and in 1953, 36 per cent. This would account for 5 points of the estimated decline from 14 to 2 in average theater net profit as a percentage of box office receipts. Evidence also shows that the smallest theaters have been the hardest squeezed.

This upward shift in rentals, due in large part to the trend toward fewer, more expensive films, is linked with divorcement in another way, also. The big producers, no longer owning theaters and making their money on film rentals rather than at the box office, have become sharper bargainers. This is well illustrated by the 70 per cent (twice the average figure) which is now being demanded for some of the big features like *The Robe* and *The Caine Mutiny*. Moreover, competitive bidding has replaced bilateral negotiation as the means of settling terms in many hundred "situations." When the District Court originally ordered bidding, the Supreme Court eliminated the order; but it has developed anyhow. The Paramount decree having opened the possibility of an earlier run for independents, the question arose who was to get a feature which two or more theaters wanted on the same "day and date." Two solutions emerged: when the competing exhibitors were friendly, they would adopt a "product split"; that is, would alternate the sequence in which they showed successive features (thus violating the antitrust law, although with no risk of prosecution); otherwise the distributor could avoid accusations of favoritism only by asking for sealed bids.

One who makes a sealed bid is tempted to offer as much as he can afford, whereas in a straight negotiation he can bargain, hold his cards close to his chest, and threaten to walk out. The resulting rental rise in bidding situations is more important than the question whether some distributors handle bids unfairly, as unsuccessful bidders may claim. Unsuccessful bidders often include independent theaters which have demanded early runs but cannot outbid their larger rivals.

The Allied States Association, after vainly demanding that rentals be made subject to arbitration—a demand which won sympathy from neither distributors, the Department of Justice, nor the Senate Small Business Committee—has turned to a proposal that the industry be declared a public utility and its wholesale (not retail) prices regulated by the Federal Trade Commission. This threat, it hopes, can be traded for lower rentals.

A third reason why exhibitors are not happy about the decree is the abolition of block booking. The time and cost saving in buying all at once was considerable, the assurance well ahead of time that they could plan on their features for the big holidays was pleasant, and their hope of finding a "sleeper," or good film whose potential would emerge only upon its showing, matched their expectation of being given some "dogs" which they might not even want to run. On my questionnaire, twenty-nine exhibitors expressed the wish to have block booking restored as against eleven who opposed it and one who did not care. Some noncompeting theaters buy several pictures at a time today, but distributors are likely to frown on this because of legal doubts or the belief that renting one at a time makes it easier to get the maximum price for each.

Before leaving the exhibitors, I must at least mention the new and powerful forms of competition which hit them just as they were hoping to profit from the Paramount decree. With television we may lump all the new influences that keep people out of theaters, from night baseball games and tending suburban gardens to the cost of baby sitters and of parking space. A COMPO survey showing a continuous decline in theater net income from the 201 million dollar peak in 1946 to 24 millions in 1953 is consistent with the estimated 45 per cent decline in attendance. The same source reveals that in 1953, 29 per cent of theaters were losing money and another 38 per cent making it only because of concessions, of which popcorn earns the most profit.

The second new type of competition has been the drive-in theater. Between 1946 and 1954, COMPO gives their number as increasing by 3,750, while that of "four-wall" theaters declined by 4,400. The greater impact of television and drive-ins has taken the attention of some four-wall exhibitors off the antitrust situation but made others

all the more anxious to pull some rabbit out of that hat. On my questionnaire, seven called the Paramount decree good, eleven called it bad, three (correctly) said it was both, and twenty had not felt it at all.

To the independent producers, I can give only a few words. The government hoped that, once the majors owned no theaters, independents could dispose of their pictures in an open market. It is true that far more independents are active now than a few years ago, but apparently not because of greater ability to get their pictures into theaters. There were always more than 15,000 theaters that had no ties to majors; even the producer-owned theaters did not dare pass up box office hits like *The Best Years of Our Lives* or *Snow White and the Seven Dwarfs;* and most good independent films have always been released through the distributing offices of the eight defendants or even, as in the case of *Gone With the Wind,* financed in part by them. More important than the decree in accounting for the rise of independents is the increasing preference by the majors for profit participation plans as against the fixed charges of salaries of directors and stars, along with their declining production schedules which give them studio space to rent out.

The defendants, as has often been the case after antitrust defeats, seem not to have suffered very seriously. Their earnings are sharply lower than in their big years, 1946 and 1947, but television and other substitutes for the movie habit offer an adequate explanation. With the rush of successful pictures since 1953, perhaps aided by program boredom on the part of those who have owned TV sets several years, their profits have at last turned up strongly. Getting rid of theaters just when television was striking was by no means pure loss.

As to the newly divorced circuits, they have done better than one might have expected. The theaters sold under the decrees have often been their worst earners, and their remaining large theaters have had more financial backing than most independents to install technical improvements like Cinemascope and stereophonic sound and thus to share in the recent box office gains from the popular pictures using these techniques. The Stanley Warner circuit owns Cinerama, and United Paramount Theaters has merged with American Broadcasting Company. Had Paramount Pictures and Theaters not been divorced, the Federal Communications Commission would hardly have allowed this new form of integration.

One respect in which the big producers have been hit is as treble damage defendants. Although many such suits are settled by giving the plaintiffs their legal fees and the right to a prior run whose denial had been the ground of their suit, the defendants have lost several and paid substantial claims. Pending suits demand damages of more than half

a billion dollars, exceeding the net worth of all defendants combined. Eventually the statute of limitations, the crystallizing of new distribution patterns, greater caution by the courts in the face of such a Pandora's box, and perhaps an industry arbitration system should dry up the flow of new suits.

Last comes the public. How has it fared as regards quality, price, and convenience? The government's hope was that, with bad pictures no longer floated by block booking, with majors forced to rent their features in an open market, and with all theaters available to show independent films, quality would improve. I asked an officer of an exhibitor trade association about this, and he replied: "The exhibitor is constitutionally unable to judge quality except by box office; why don't you ask the film critics?" So I asked, and heard from thirty-two who said that quality has improved, one who denied it, and the *New York Times* critic (incidentally, the most influential in the country) who told me courteously but plainly that quality is too complex a topic to discuss in that fashion. Three critics felt that the improvement which they observed could be credited to divorcement, twelve said no, and seventeen saw no clear connection. If, however, the decree was one factor which caused the big producers to cut down the number of their pictures and increase the time and money spent on each, it would seem that quality should have improved, and the decree thus get part of the credit.

Several of these factors might have been expected to put box office prices up: (1) higher distribution costs with the abolition of block booking; (2) harder bargaining by producers, who sometimes admit, or insist, that their terms on a particular picture can be met only if theaters raise their prices that week, but who avoid contractual resale price fixing such as the Supreme Court condemned in the Paramount decision; and (3) the tendency of some theaters, because they have stepped up their runs, to raise prices. If this third tendency went to its logical limit, neighborhood theater prices would rise, and downtown prices be forced down by slumping attendance as people could see early runs at home—thus presumably reducing the variety of price-and-product packages available to consumers. Although one may guess that these effects will be small, price statistics are not clear. The Bureau of Labor Statistics index of admission prices, hidden in the "Reading and recreation" component of its consumer price index, has increased 20 per cent since 1948, but industry estimates of the increase in the net price after deducting admissions tax range from the *Motion Picture Herald's* 11 per cent for 1954 to the *Film Daily Year Book's* 53 per cent for 1953. The fact that attendance has switched from smaller to larger theaters and also from daytime and weekdays to eve-

nings and holidays, plus the fact that an undetermined number of theaters, but probably most, made little or no cut in price when the excise tax was lowered last April, muddy the waters further.

Convenience has been improved for some members of the public, worsened for others. The reduction of unreasonable clearances has been good for all; but the 16 per cent of adult moviegoers who attend more than once a week may have felt the "product shortage." The old problem of too many theaters showing the same feature the same week has been intensified by the stepping up of runs, although other causes have operated—like co-ordination of showings with advertising campaigns and economies of buying a picture for all theaters in a circuit at once (technically, to be sure, on a "theater by theater" basis). How a picture may come and go, before the whole potential audience realizes it, is illustrated by the 200,000 people in the Chicago area who (according to a survey by a theater circuit) were still waiting for *Quo Vadis* to come to their suburban theaters long after it had been shown. Members of the public who are not bound by old habits, and are more anxious to see the newest thing, are better pleased. As I wrote this, five of the eight theaters in my immediate neighborhood were showing *Seven Brides for Seven Brothers,* and my daughter had managed happily to see it four times.

The morals I draw will be brief. (1) Vertical disintegration can, as would be expected, effectively remove the danger that integrated firms will abuse their power. (2) It may, however, boomerang on the supposed beneficiaries. Although the more ambitious exhibitors have won their chance to fight on equal terms with the big circuits, others would prefer the old days with their well-established grooves. (3) Disintegration may have mixed effects on the public—as, in this case, very likely better quality but possibly higher prices and perhaps more patrons convenienced than inconvenienced. (4) Antitrust decrees are likely to have less influence on an industry than either competition of other commodities and services or shifts in population and consumer habits, of which television and the drive-in, respectively, are the prime examples here.

On net balance, this experiment in disintegration is not without its hopeful aspects, but its results to date are better characterized as disappointing than as clear or important.

THE DECLINE OF MONOPOLY IN THE METAL CONTAINER INDUSTRY

By JAMES W. MCKIE
Vanderbilt University

I

The Clayton Antitrust Act is now over forty years old, and economists are still uncertain about its role in antitrust policy. Most would doubtless agree on the need for some instrument that is more flexible than the Sherman Act. That Act cannot be applied until monopoly control is well established, and one purpose of the Clayton Act has always been to prevent monopoly by arresting it in an incipient stage. Its success in this respect has been mixed; many persons have pointed out of late that a policy of prohibiting competitive practices that could eventually result in monopoly may be leading us toward per se rules of business conduct that are impossibly confining. But the Clayton Act has also been used against business practices in markets that already have a monopolistic structure. Sometimes this has been done merely to provide a bill of particulars in cases tried chiefly under the Sherman Act; but sometimes it has been done in an attempt to weaken monopoly through an attack on its manifestations. Doubts have also centered on the wisdom of this latter policy, on the ground that it does very little good to prohibit a market practice if the underlying monopoly power which makes it oppressive remains untouched.

The American Can case of 1950 illustrates in almost unexpected circumstances the force that the indirect and peripheral approach of the Clayton Act may have to make competition more effective. This was a case in which a specific market practice was the key to market power. The practice had nothing to do with the creation of market power, since it supervened upon a monopolistic structure that was already there; but it played a decisive part in the maintenance of market control after the foundations of monopoly had been undermined.

A cursory examination of the structure of the metal container industry just before the antitrust suit began in 1948 might well have made anyone skeptical of the success of a policy which did not involve fundamental structural reorganization. The industry was highly concentrated, and still is: the two leading firms, American Can Company and Continental Can Company, together accounted for nearly 80 per cent of total sales, and American alone had over 45 per cent.[1] There were in

[1] *United States of America* v. *American Can Company*, Civil Action No 26345-H. In the United States District Court for the Northern District of California, Southern Division Exhibits UU and 3124 (Stipulation on Statistics, March 31, 1949).

addition a number of small sellers—no one of them more than one-eighth as large as American—which occupied sheltered and specialized positions or else appeared to subsist on a margin of tolerance. The major companies manufacture a product-mix of containers for different purposes, but differentiation within each product line was and is insignificant. Cross-elasticities of demand between metal cans and substitute containers are very small. The prices of the two leaders, as well as their other market policies, have long been substantially identical. Prices for given products in given sales regions were set by one of the large firms, the other following; a policy of universal freight equalization eliminated the uncertainties of geographical differentiation; and prices exhibited the characteristic rigidity that we have come to associate with tacit oligopolistic collusion.

Tacit collusion in circumstances like these might be expected to result in the maximization of joint profits. However, the maximization of joint profits is always subject to limitations in any oligopoly structure, and in some instances the limitations are so severe that the principle loses its explanatory value. Economists have long preferred an eclectic approach to this problem. No universal solvent has yet been found that will exempt us from a detailed examination of the structure of particular oligopolistic markets and their history, as a prerequisite to explaining their behavior. The limitations upon monopoly power are often hidden from immediate view. A detailed analysis of the metal container industry reveals a number of them.

II

There is time for only a brief summary here. The first thing to be noted is that the limited-duopoly structure in the can industry is a relatively recent development. Twenty years ago any industrial economist would have classed the industry with those dominated by a single firm. American Can was organized originally as a trust controlling virtually the entire capacity of the industry. It suffered the fate of many of the trusts organized at the turn of the century: the umbrella it held over the industry encouraged the growth of competition, and within a dozen years its share of the market had fallen to 50 per cent. It was about this time, in 1916, that American was first charged with monopoly under the Sherman Act. Professor Hession in his able study of the food container industry (*Competition in the Metal Food Container Industry, 1916-1946* [Brooklyn, 1948]) calls American Can "the trust that wasn't busted." The court refrained from dissolving it principally because of the rapid decline in its market share, and the judge expressed the hope that the growth of rivals would soon restore competition in the industry.

Competition was not quickly restored. American possessed nothing approaching pure monopoly after 1916, but it remained the dominant firm. Its market share ceased to fall, and its capacity remained for a time enormously greater than its rivals'. American's prices determined the prices for the whole industry. It maintained its lead by rapid development and expansion from within. Nevertheless, its power to control the industry was considerably weaker in 1948 than it was in 1916.

This slow metamorphosis was due partly to developments within the industry, partly to the impact of the antitrust laws. The structure of the industry altered gradually as Continental Can began to challenge American's leadership. In 1916, Continental was a small cloud on American's horizon, hardly distinguishable from a number of other small rivals. Throughout the following decades, Continental grew rapidly with a bold program of acquisition and merger as well as by rapid expansion from within. By 1939, it was half as large as American; by 1950 it was three-fourths as large. Its growth eventually put it in a position that rivalled American's. Prior to the middle thirties, American was the only metal container manufacturer with an important research program and was practically solely responsible for the progress and development that had occurred up to that time. Moreover, it was the only manufacturer up to then that was fully able to realize certain other advantages of scale. These are not production economies, but are achieved through the interlocking of separate plants so that the extreme uncertainties of demand for food containers in any one area are diffused along a chain of production sites. The ability of American to offer certainty of supply, together with its facilities for research and customer service, made it the only acceptable source of supply to many buyers of cans, including most of the large and stable ones, until a second large seller appeared.

By the end of the thirties, American was at last confronted with a powerful, efficient, and progressive rival in practically every geographical region and every product, including many in which American had earlier enjoyed a monopoly. It took time for Continental to break into the geographical strongholds of American and to build up an effective and experienced research staff, but in the end the supremacy of American was undermined.

Conditions were more stringent for the smaller firms. No other was able to achieve anything like the growth of Continental; in fact, several of those which had begun to grow to substantial size were acquired by Continental. A few producers of food cans managed to build up integrated regional organizations, securing at least part of the advantages of size, and compensated for their inferior research and service facilities

by charging somewhat lower prices. Two firms even succeeded in entering the industry and establishing themselves in the food can market. All of these smaller producers were potential bases for expanded competition; that this potential was not fully realized was due to certain market practices of the larger firms which held the smaller ones in check.

A significant change was forced by the tightening of the law against price discrimination after 1936. The Robinson-Patman Act affected two markets: tin plate and tin cans. Tin plate accounts for 60 per cent of metal container costs. In the days of the Steel Trust and the Can Trust the tin plate market was almost a classic bilateral monopoly. The monopolies on both sides lost their near-exclusive control, but the "leading bargain" between U. S. Steel and American Can continued to determine the price of tin plate. In this market it appeared that monopoly power was offset by monopoly power. The benefits of this countervailing power, however, were mixed. Improvement and development in the tin plate industry, for instance, have been rapid and considerable, and there is no doubt that the large buyers, especially American, have pressed the steel producers closer to the maximum attainable rate of progress—both in product improvement and cost reduction—than would have been the case if buyers had been small and impotent. On the other hand, the price benefits of countervailing power filtered down to consumers very slowly; it requires a substantial degree of competition in subsequent markets before countervailing power in a prior market amounts to anything more than a division of spoils. One result of American's dominant position as a buyer of tin plate in the early years was that the tin plate producers favored it with secret rebates and systematic price discrimination. After a second buyer of substantial size had entered the market a new dimension of strategy emerged, and price reductions negotiated between individual buyers and sellers became more difficult to confine to the largest buyers. Nevertheless, systematic discrimination continued in various forms up to the passage of the Robinson-Patman Act, at which time American actually capitalized its claims to discriminatory treatment and liquidated them by accepting substantial lump-sum settlements from United States Steel and other suppliers. After 1937, countervailing power was exercised in behalf of all buyers of tin plate. This benefited the ultimate buyers of cans only insofar as there were limits to the exercise of monopoly power in the can market.

The buyers of cans were themselves not entirely helpless, though none had anything like the bargaining power that American had in the tin plate market. Even in the days when there was only one large

can manufacturer, the big canning companies had the option of manufacturing for themselves. Backward integration is not extremely difficult for a large user, and it would have taken only a slight widening of the profit margin on cans to make it economical. Potential entry from the buying side limited monopoly power on the selling side. At first the result was systematic, secret discrimination in favor of the buyers who could offer this threat. After a second seller grew to large size, the bargaining position of the large buyers was strengthened, since they could play one off against the other. The Robinson-Patman Act obliged the major can companies to abandon secret discrimination. It was replaced, not by uniform prices to all buyers, but by an open schedule of volume discounts, which eventually came to be based on total purchases of all kinds of containers from the supplier. The discounts were greater for large-volume purchasers than any concession that the smaller can companies could easily offer, and there is no doubt that these discounts worked to their disadvantage. On the other hand, the continuous alteration and reshaping of the discount structure did afford a means of limited price competition between the two leaders; and the large buyers had at least the potential power to enforce this competition between them.

III

Though the monopoly power once possessed by the dominant firm had been markedly eroded by 1950, the effect of the underlying structural changes on competition remained more potential than actual. The reason was that the leading firm followed several policies which concentrated its remaining market power in the most effective way, and its large rival did likewise. There were three important instruments of commercial dominance. The first was the volume discounts just mentioned. The second was the practice of selling under long-term requirements contracts. It is fair to say that neither of these could have had a powerful enough effect to justify action under the antitrust laws, though they did tend to reinforce each other. The contracts were written for specific containers for use at specific plants. Smaller can companies occasionally succeeded in becoming secondary suppliers of large buyers, but it was the usual practice for a buyer to concentrate all his purchases on a single source of supply. There were some buyers whose purchases considerably exceeded the volume necessary to get the highest discount that was offered, but most of these also had long-term requirements contracts with a single supplier or, less frequently, split their purchases between American and Continental. The amount of business that the smaller can companies were eligible to compete for at any given time

was thus restricted. Volume discounts were partly responsible, but the superiority of the two large sellers in research and customer service may have been equally important in determining the result.

The third instrument of control was the practice of tying the lease of can closing machinery to the sale of cans. (This was not done through an explicit tying clause, but by arranging the expiration dates of separate contracts so that no canner would be able to retain American's machinery to close competitors' cans. There were minor exceptions.) This requires a word of explanation. If the manufacture of closing machinery had been perfectly competitive, the larger can companies would have gained no net advantage by this practice. But American's can machinery has long been recognized as the best and most complete in the industry, and its progressiveness in this field is beyond dispute. Continental began late, but was overtaking American rapidly in the late thirties. Both large firms followed the same policy. Rentals on closing machinery, which also covered servicing by the manufacturer, were set below actual cost, to induce buyers to lease machines. Most can buyers were allowed to retain the machinery only as long as they purchased the cans to be closed on it from the same firm. The moderate advantage which the major sellers possessed in closing machinery was thus extended forward and magnified in the can market. The relation between supplier and customer became harder to break. (Closing machinery is generally unimportant for nonfood cans, and both major companies faced much more vigorous competition from independents in this field.) In markets for food cans, the smaller manufacturers were forced to imitate the leasing practices of the majors; but since they had to buy somewhat inferior closing machines on the open market and lease them at below-cost rentals, they reaped no comparable advantage. (One or two of the smaller companies also entered the manufacture of closing machinery, without much success until recently.) A side effect of the practice was that no canner would buy machinery in preference to renting it, and independent machinery manufacturers faced an uneconomically thin market.

IV

The government might have attempted a major Sherman Act case, with wholesale dissolution and structural reorganization of the industry as the objective. But this would have been risky, since the specific charge of monopolization had been tried in an earlier case and the judge had refused the suggested remedy of dissolution. Instead, the government attacked the practice of tie-in sales directly under Section 3 of the Clayton Act, retaining a Sherman Act charge to scoop in the requirements contracts if possible and to provide for equitable relief.

There is some evidence that the Antitrust Division was not entirely satisfied with the form that its case eventually took in consequence, but it won the case nevertheless. The court decided that American had violated both the Clayton Act and the Sherman Act.[2] In addition to a number of minor matters, which need not concern us here, the 1950 decree altered market practice in the metal container industry in three ways. (Continental accepted the same judgment in a consent decree.)

1. The major firms were prohibited from offering any annual cumulative volume discounts.

2. Requirements contracts were limited to one year. American Can had presented convincing evidence that requirements contracts are necessary to protect food canners, in view of the great uncertainty of crop yields and timing, and that canners preferred them to fixed-quantity contracts; hence the court did not prohibit them altogether. The court also ordered that separate contracts be written for individual plants when the customer had more than one cannery. The buyer could still place all his contracts with a single seller if he chose, but smaller can manufacturers would find it easier to bid at least for the business of a single plant of a multiplant buyer.

3. The tie between machine leasing and the sale of cans was broken. The major companies were permanently enjoined from conditioning the lease of machines on the sale of cans, by any subterfuge. In addition, they were ordered to sell their existing closing machines at bargain prices to anyone who wanted to buy them, giving priority to existing lessees. This order applied to all machines to be built in the future as well, for a period of ten years. The can companies were required to make all technological information and know-how available to buyers, to set up schools to train service men employed by the canneries, and to license closing-machinery patents without royalty. The court recognized that there were certain advantages to integration between machinery manufacture and can manufacture, since can manufacture and can closing involve much the same technology, and so it did not order divestiture. The can companies were required to lease to everyone any machine that they were then leasing to anyone. Moreover, rentals had to be fully compensatory, including a fair profit, after the end of 1953. (Continental has asked for a postponement. Fully compensatory rentals on its diminished stock of equipment would be prohibitive, it claims, since overhead has not been proportionally reduced.) No more could below-cost rentals be used as an inducement to lease.

[2] 87 F. Supp. 18 (1949). A simultaneous case against Continental was not brought to trial, Continental having agreed in advance to accept any judgment entered against American, short of divestiture.

V

This decree knocked out practically all the remaining props of market control. The decree has been in effect now for over three years. Some of its consequences have been striking. One instance is the sale of closing machines, which has greatly exceeded everyone's expectations. The can manufacturers had claimed that customers would be reluctant to buy them—that customers would prefer to lease instead and pay the supplier the appropriate fee for bearing the risk of obsolescence and the task of servicing and maintenance. If this reluctance ever existed it was quickly overcome. The bargain prices the court set on the machines existing in 1950 made it uneconomical not to buy them, and in addition American and Continental, in wholehearted compliance with the letter and the spirit of the decree, have made vigorous efforts to sell both old and newly manufactured machines. By the middle of 1954 both American and Continental had sold over 75 per cent of the closing machines they were leasing in 1950. While the lease market may revive in the future, can buyers are no longer heavily dependent on their can suppliers for closing machinery, and there is no way now for the machinery supplier to apply commercial leverage to the can market. After the transition period is over, the independent manufacturers of machinery will be able to market closing machines directly to the canning industry, and they have already responded to this broadening of their opportunities.

A second result has been an extensive breakdown of exclusive supplier-customer relations. While fruit and vegetable canneries have largely continued their requirements contracts, the large packers operating several canneries have begun to allocate them to different suppliers. Other canners have begun to split requirements within the plant, closing cans from several suppliers indiscriminately on the machines of several manufacturers. There has been an enormous growth in open-order purchasing at the expense of contract purchasing. Small firms are now better able to detach fragments of business which used to be held firmly by the large can suppliers. They can enter large-volume markets either by carrying off supply contracts for individual canneries in a chain or by becoming secondary sources of supply within the plant. The vertical partitions in the market which formerly made the ties between particular buyers and sellers very strong have been demolished, and competitive forces, wherever they originate, can sweep across it largely unimpeded. The market position of smaller manufacturers has been greatly strengthened.

It is interesting to note that these changes in the can market have been accompanied by some instability in the tin plate market. At least part of this instability has been transmitted backward from the

can market. Prices have become more flexible; open-order purchasing has grown in volume; the leadership of the leading bargain between U. S. Steel and American Can has weakened further. The tin plate suppliers still feel the weight of the large buyers' bargaining power, but this is more likely now to work to the benefit of ultimate consumers of cans.

It is possible of course to expect too much of the decree. The gross structure of the industry has not changed very much and probably will not change much in the immediate future. Doubtless the effects of a decree of dissolution, if American had been convicted of illegal acquisition and maintenance of monopoly, would have been more spectacular. Several firms could have been fashioned out of either of the leaders without an appreciable loss of efficiency, and the market would in time have enforced a high degree of competition among the fragments. However, such a monopoly charge could not have been sustained. We must decide whether we have any better ground now than the court did in 1916 for expecting workable competition in the future.

American and Continental together would still be able to dominate the industry in the short run if they maintained effective collusion in every dimension of the market. But instead the two large firms are in a state of intense rivalry. The challenger is staging a vigorous drive on the markets of the leader. A number of large accounts previously held by American have now been split. Technological rivalry is unrestrained. While open price warfare has been avoided, except in a few local instances, there is protracted maneuvering in an atmosphere of great uncertainty when the time for quoting new prices and renewing contracts comes round every year. American's price leadership is now merely barometric, and it cannot count on being followed by Continental or by any other seller.

The smaller firms, aided by a strong growth trend in the industry, have been establishing themselves on a more secure footing and have also been edging into the markets of both the leaders. In several instances recently the price structure of the majors has had to be adapted to the independent competitive tactics of a smaller firm aggressively reaching for a larger share. Although the oligopoly structure remains, enough has been said to show that the competitive pattern is in a state of flux.

No outsiders have entered can manufacture in the last three years, but the threat of entry from the buying side has been intensified. Large buyers can no longer be pacified with volume discounts. During the past year the very largest consumer of packers cans began to manufacture part of its own requirements, and another large buyer, located in one of American's few remaining monopoly territories, has announced

plans to manufacture all its own containers. The effect of these events is incalculable. Both of the large sellers are constrained as never before by the threat of backward integration, and the restraints exercised on profit margins in cans work to the benefit of all buyers.

American itself has no monopoly weapons left in its hands. Any firm which relies on size and the momentum of past achievements alone to protect it against competition is likely to find its position deteriorating with alarming speed. What American can do is to take advantage of the moderate superiorities it evidently has in efficiency and research. It can maintain its leading position by reducing costs and continuing its rapid rate of product development, passing along the benefits to consumers. Its large rival will push it, or perhaps lead it, in this respect. Its smaller rivals will offer a stronger competitive challenge as time goes on. And its large customers will never be more than a few years behind in potential efficiency if they should decide to produce their own supplies. A forecast of workable competition appears to be justified. Thus it seems that the Antitrust Division, in choosing to make a limited attack on market practices—however much it may later have doubted its own wisdom—made a good decision after all.

THE BASING POINT DECISIONS AND THE STEEL INDUSTRY

By Louis Marengo
Washington, D.C.

Until a few years ago, the basing point system was used in a number of important American industries, including the iron and steel industry, the cement industry, the corn wet milling industry and others. Several Federal Trade Commission (FTC) orders, some adjudicated and some not, have put an end to the system; the key case was undoubtedly the one against the cement industry, on which the Supreme Court ruled in 1948. The purpose of this paper is to examine the effect of these decisions, with particular reference to whether they will significantly increase price competition in the former basing point industries.

The first step will be to discuss some of the rulings of the FTC and the courts and to assess their impact on the basing point system and their general economic significance where appropriate. The next step is to determine if possible whether the rulings will produce a greater degree of price competition in the former basing point industries. The discussion will be particularized for the iron and steel industry, which until 1948 used a multiple basing point system. The final few paragraphs will be a description and brief analysis of events in the steel industry since the end of the basing point system.

The term "basing point system" will frequently be used without qualification, even though the system has taken several forms. Sometimes the context will make clear what form is referred to. More often, the reference is intentionally generic; i.e., to a method of pricing which regardless of variations in detail permits only delivered pricing, and makes the price to a buyer the lowest combination of basing point price and outbound rail freight charges, regardless of the actual location of the seller and regardless of the form of transportation actually used.

I

Beginning in 1937, after years of inactivity in this field, the Federal Trade Commission issued a number of complaints against firms and industries using the basing point system. The Commission challenged single basing point systems used by the Corn Products Refining Company and the A. E. Staley Manufacturing Company and multiple basing point systems used in the cement, rigid steel conduit, iron and steel and corn wet milling industries. Three other complaints against the Morton Salt Company, Samuel H. Moss, Inc., and the Standard Oil Company (Indiana), though not concerned with basing point pric-

ing, produced applicable interpretations of the Robinson-Patman Act. All of these complaints except two have been adjudicated; the corn wet milling order was accepted by the industry and the steel order was negotiated between the parties.

It is not necessary for present purposes to discuss these cases one by one; a short and unfortunately rather dogmatic summary should suffice. It will be convenient to divide this summary into two parts, corresponding to the two laws upon which the Commission has relied: the Federal Trade Commission Act and the Clayton Act as amended by the Robinson-Patman Act.

The Federal Trade Commission Act declares unlawful "unfair methods of competition in commerce, and unfair or deceptive acts or practices in commerce. . . ." The Commission has used this act to attack basing point systems as combinations, conspiracies, or planned common courses of action. Recent adjudication has established the following:

1. *A basing point system used pursuant to a combination or conspiracy is an unfair method of competition.* This conclusion would seem so obvious as to require no justification. Notwithstanding, respondents in the Cement case challenged the jurisdiction of the Commission, on the grounds that the combination of which they were accused was an offense under the Sherman Act, against which the Commission could not proceed. The Supreme Court ruled that the Commission had jurisdiction under the Federal Trade Commission Act even if the offense also violated the Sherman Act. The Court added that individual or concerted conduct falling short of a Sherman Act violation could still violate the Federal Trade Commission Act.

2. *A combination or conspiracy need not be proved by direct evidence; it may be proved by circumstantial evidence, including evidence of market behavior.* Ruling in the Cement case, the Supreme Court stated that the Commission was authorized "to find understanding, express or implied," from evidence that the industry's institute worked to maintain the multiple basing point system, that the pricing system produced uniform (sic) prices, and that respondents followed the system. The Seventh Circuit Court of Appeals in the Rigid Steel Conduit case stated that an agreement could be shown by circumstantial evidence, including evidence of price conformity and of the existence of a plan which equalized delivered prices. These decisions give to economic tests a substantial place in determining desirability and legality. They also open the door to orders which can strike not only at written agreements but also at the economic acts which agreement may have been designed to perpetrate.

3. *Although not clearly established, it is possible that basing point*

systems are illegal per se. The FTC complaint in the Rigid Steel Conduit case was divided into two counts, each alleging a violation of the Federal Trade Commission Act. The first charged the existence of a conspiracy, effected by use of the basing point system. The second, however, did not charge combination, conspiracy or unlawful discrimination. Instead, it charged that the sellers individually violated the Federal Trade Commission Act "through their concurrent use of a formula method of making delivered price quotations with the knowledge that each did likewise. . . ." The cease and desist order included prohibitions based on both counts and was upheld by the Circuit Court. The Supreme Court, by a vote of 4-4, refused to overrule.

The impact of this case on basing point pricing is still not clear. On the one hand, the Commission brief before the Circuit Court stated that Count 2 was "frankly directed against the basing point practice as being, *per se*, an unfair method of competition. . . ." On the other hand, members and employees of the Commission later denied that basing point systems were under attack as such and argued that the Conduit case was basically a conspiracy case. The statement in the brief probably reflects the Commission's true intent; it is significant that the later statements followed anguished howls from the business community and the start of hearings by a Congressional committee.

The Clayton Act as amended states "that it shall be unlawful . . . to discriminate in price . . . where the effect of such discrimination may be to substantially lessen competition or tend to create a monopoly. . . ." Certain price differences, however, are exempted. The exception for lower prices "made in good faith to meet an equally low price of a competitor" is the only one relevant to a basing point situation.

In order for a basing point system to be found unlawful under the Clayton Act, it must be established that (1) it leads to discrimination in price, (2) the discrimination may lessen competition, and (3) the discrimination is not justified in one of the ways provided by law. Adjudicated cases seem to establish the following on these points:

1. *A discrimination is merely a difference in price.* The Supreme Court ruled in the Morton Salt case that the Federal Trade Commission, to establish a discrimination in price, had only to show that a seller had charged one purchaser a higher price for like goods than another purchaser. The legality or illegality of the discrimination would depend on whether the seller positively justified it in a way provided by law and on whether it had an adverse effect on competition.

2. *In a basing point situation, price is not the delivered price paid by purchasers, but the mill net realized by sellers.* In all of its basing point complaints, the FTC has considered price to be the seller's mill net, defined as delivered price less the cost of transportation from

seller's plant to place of delivery. Under this definition the basing point system necessarily produces discrimination, because sellers regularly absorb freight on some sales. Producers located at basing point have objected vigorously to this concept. They argue that delivered prices on freight absorption sales are the same as those charged by the mills whose prices are being met; hence, there can be no question of unlawful discrimination.

This argument is neither convincing nor necessary, the latter because freight absorption can be justified on other grounds. Any firm selling on a delivered basis will of necessity discriminate in price, unless its customers are located at a common point. However, its price differences are legal when they correspond to differences in the cost of delivery; they are also without fault economically as long as the cheapest forms of transport are used. If not, then *ceteris paribus* there is a misallocation of resources. If, however, a firm absorbs freight, its differences in delivered price no longer correspond to differences in the cost of delivery, and may be illegal no matter how price is defined. Its discriminations are suspect from an economic point of view because they lead to a possible misallocation of resources.

3. *It is not necessary to find that a price discrimination has injured competition, but only a reasonable possibility that it may.* Price differences constitute discrimination, but not all discriminations are unlawful; to be unlawful, a price discrimination must be injurious to competition. The Supreme Court, in both the Corn Products case and the Morton Salt case, held that it was not necessary to find actual injury to competition but only a "reasonable possibility" that it might occur. The Court went even further in the Morton Salt case, when it ruled that the Robinson-Patman Act justified a finding of injury to competition by showing "injury to the competitor victimized by the discrimination."

Some lawyers fear that an irresponsible Commission, freely interpreting the doctrine of reasonable possibility, will initiate complaints based only on a remote potentiality. But the Commission, in its 1948 statement of policy, denied any intention of doing so; the courts, in any event, would undoubtedly not permit it. On the positive side, the doctrine of reasonable possibility simplifies proof and permits the prohibition of practices which to an economist are clearly a danger to competition but which in the past have not met the rather legalistic tests of the courts.

The ruling which equates injury to competition with injury to a competitor is the really controversial one. Given pure competition as a standard, there is no place for price discrimination; since discrimination is a sign of monopoly, and monopoly and competition are mutually exclusive, the elimination of discrimination must perforce promote com-

petition. When the attainable and hence the standard is something other than pure competition, the answer is not so simple. It is still true, of course, that discrimination is the product of monopoly power. It is no longer true, however, that discrimination is necessarily anticompetitive. In a market where small numbers makes possible control over prices, as in the typical basing point industry, price discrimination has been a powerful competitive force when it actually undercuts rivals' prices.

It is in precisely these industries, however, that any competition in price, including price discrimination, will immediately and substantially affect a competitor. Hence, the two cannot be equated unless one is willing to give up competition altogether.

4. *The good faith defense of section 2b of the Robinson-Patman Act is an absolute defense to a charge of price discrimination, but probably not in a basing point situation.* The FTC ruled in the Standard Oil case that the good faith defense was procedural rather than substantive. As such, it was ruled not admissible if the Commission affirmatively showed injury to competition. The Supreme Court disagreed, stating that "we find no reason to destroy the defense indirectly, merely because it also appears that the beneficiaries of the seller's price reductions may derive a competitive advantage from them or may, in a natural course of events, reduce their own resale price to their customers."

It is doubtful, however, that the Court would have ruled the same way in a basing point case. In the Staley case, the company argued that it had adopted its single basing point system in good faith to meet the competition of the Corn Products Refining Company. The Court held that section 2b "does not concern itself with pricing systems or even with all the seller's discriminatory prices to buyers. It speaks only of the sellers' lower price. . . ." In its Cement decision, the Supreme Court cited the Corn Products decision and this portion of the Staley decision, and concluded that "the combined effect of the two cases was to forbid the adoption for sales purposes of any basing point system."

These statements have been disconcerting to sellers in the basing point industries. Basing point pricing involves the regular meeting of competitors' prices. The alternative is either to meet competition on an individual basis or not to meet it at all. If a seller meets it on an individual basis, he must still know how frequently and comprehensively he can do so without becoming systematic in the eyes of the law. As an executive of the United States Steel Corporation once put it, to attempt to handle 3,000 orders per day and to meet competition without following what appeared to be a systematic method was commercially impractical.

II

The FTC and the courts have clearly dealt a fatal blow to the basing point system. Adjudicated cease and desist orders have eliminated exclusive delivered pricing, the exclusive use of rail rates in the calculation of delivered prices, the industry-wide preparation and dissemination of freight rate books, and the plant which fails to quote a base price. The orders have probably also eliminated the systematic, routine meeting of competitors' prices, but probably not the individual noncollusive absorption of freight.

The important question is whether the decisions will lead to a greater degree of price competition in the industries which have used the basing point system. Views on this subject, though many and varied, tend to cluster around two poles. One general view is that the basing point system is an essential ingredient of combinations and conspiracies, which could only with difficulty be carried on without it, if at all. Hence, its elimination is per se a decisive step in promoting price competition. Some holders of this view go a step further by advocating the complete elimination of freight absorption, even if practiced individually. The other general view is that the basing point system developed quite logically and more or less inevitably from certain market characteristics, and that something like the basing point system is certain to be found in industries having these characteristics. Hence, the elimination of the basing point system insures neither a radically different method of pricing nor a markedly greater degree of price competition. These views may be called for convenience the collusive and the oligopolistic.

Since the industries which have used the basing point system have many characteristics in common, it is tempting to pursue this argument in general terms and to make what is said apply to all of them. There is the very practical objection, however, that no one person, or at least not this person, can speak with such broad authority. Moreover, significant differences among these industries do exist. Therefore the ensuing discussion will be restricted to the iron and steel industry. It may be suggested, however, that the discussion is at least broadly applicable to all the industries which have used the basing point system.

We start with the proposition that the nature and degree of price competition in an industry depends on the presence of various market characteristics or elements and the combination in which they occur. The conceptual schemes of price theory consider only a few of these elements, particularly the number of sellers and the nature of the product. The number affecting price behavior in the steel market and in other industrial markets is much greater. However, limitations of time and space will permit consideration of only a few here, which are fortunately rather decisive.

Steel sales are typically made directly by producer to consumer, without the intervention of a central market or other middleman. The steel market is characterized by the following: (1) A relatively small number of large sellers. On January 1, 1954, nineteen large integrated firms accounted for some 93 per cent of the industry's blast furnace capacity and some 90 per cent of its steel ingot capacity. The United States Steel Corporation alone accounted for 34 and 31 per cent, respectively. (2) A standardized product. Steel products are made to specification; hence, competition centers around price rather than around differences in quality, real or imagined. (3) Substantial fixed costs and a high ratio of fixed to marginal cost. (4) Freight costs high enough in proportion to sales price to be decisive in the selection of a seller. (5) A low price elasticity of composite demand but a high price elasticity of demand for the products of a single seller. (6) A significant difference between the location of capacity and the location of demand. These characteristics, with particular reference to the first two, are typical of pure oligopolies.

In the absence of collusion, what kind of price competition will result in a market with these characteristics? In the first instance, each seller would presumably name a plant price (we beg the question of what determines its level) and offer it to all comers. Buyers would purchase from a particular seller, however, only if his price was equal to or lower than the prices of cempeting sellers, taking into account the cost of outbound transportation. Hence, any given seller could do business only in his freight advantage territory; i.e., where the sum of his plant price and outbound freight costs was at least as low as that of his rivals.

Not all sellers—and possibly not any—would be satisfied to stop here. Lack of correspondence between capacity and demand, changes associated with the business cycle, changes in the pattern of demand, etc., would leave some sellers with unused capacity and a desire to increase their sales. They could do so, however, only by selling outside their freight advantage territories at delivered prices at least as low as those of their competitors; i.e., by absorbing freight and accepting lower mill nets. However, it is profitable for them to do so as long as they more than cover marginal costs, if the alternative is not to make the sale at all. There is no reason, however, for making these same concessions to buyers located within their freight advantage territories, except to meet the price cuts of a competitor. In short, there is an incentive to discriminate in price.

If sellers ignore the possible reactions of their rivals, they will act as if the elasticity of composite demand is the same as their individual elasticities of demand. That is, they will beat rather than meet competi-

tors' prices outside their freight advantage territories. To meet a price is to be less than certain that a sale will be made; to beat a price is to be absolutely certain. The difficulty, of course, is that all sellers, following the same process of reasoning, pursue the same course of action; those who suffer from price cuts retaliate. Since the price elasticity of composite demand is low, each seller experiences only a slight increase in demand and suffers an actual loss in net revenue. If each seller continues his price cutting in an attempt to recoup, the result will be cutthroat competition and prices will be driven to the level of marginal cost.

It may be argued that this description is a fanciful one, not related to anything that now happens in real life. And of course this is so, for oligopolistic sellers in real life are quite aware of their interdependence. However, the steel industry in the nineteenth century was frequently subject to cutthroat competition, and more recent episodes, particularly in the years 1911, 1921, and 1938, have brought cutthroat competition perilously close to reality. This history strongly suggests that unrestrained competition, if it occurred, would be cutthroat competition.

Bitter experience, then, if nothing else, teaches steel sellers that what one can do with profit cannot be done by all simultaneously. Hence it becomes in the common interest to avoid unrestrained competition or any competition which puts undue pressure on prices. Given this attitude and given the market characteristics of the steel industry, it is not unreasonable to suppose that a pricing system like the basing point system would develop. Sellers at a location with one or more rivals would charge their plant price plus outbound freight up to a point where a competitor's price similarly calculated was lower; then they would meet the lower price but not beat it. Isolated sellers might find no reason to quote a base price; if not, they would simply meet competitors' prices at every point of delivery. Thus would develop the familiar outlines of the basing point system with its dichotomy between base and nonbase mills.

What purpose does the basing point system serve in this context? The problem is to keep freight absorption from starting an unprofitable chain of price cuts and retaliations. This can be done if sellers follow a policy of meeting rather than beating competitors' prices outside their freight advantage territories. The basing point system makes it easy for such a policy to be carried out, for it tells each seller what every other seller will charge at every point of delivery. In effect, it eliminates the uncertainty which oligopolistic sellers normally have about their rivals' prices. One must distinguish, however, between pricing policy on the one hand and the mechanism for carrying it out on the other hand; the two are not the same. The policy, in this case, is to

meet rather than beat competitors' prices; the mechanism for carrying it out is the basing point system. The basing point system will do the things claimed for it here only if a desire to follow the policy exists in the first place. In other words, there is nothing in the basing point system which prevents the undercutting of rivals' prices if sellers choose to do it. Conversely, the policy of meeting rather than beating competitors' prices can be carried on without a basing point system, though with considerably greater difficulty. By the same process of reasoning, the basing point system does not cause discrimination; it merely keeps discrimination within certain bounds. It follows that the mere elimination of the basing point system does not remove the incentives which produced it and does not automatically lead to a radically different pricing policy.

The basing point system, in this view, has two indispensable elements: exclusive delivered pricing and a common method for calculating delivered prices. If f.o.b. sales are permitted or if delivered prices are calculated in different ways, sellers cannot know in advance the exact prices they have to meet, and the system fails to serve the purpose for which it was adopted. Freight absorption is an indispensable element in another sense, for if it is not permitted, the need for a basing point system disappears.

Those who adhere to the collusive view of the basing point system reject this line of reasoning, on one or more of three grounds. First, they argue that the foregoing description implies development of the basing point system through natural evolution, without the intervention of human will or volition. They then easily show that natural evolution could not possibly account for such a complicated and detailed method of pricing. Second, they assign quite a different role to small numbers. Fewness of sellers is considered important because it facilitates collusive agreements to use the basing point system, and not for the reasons accepted here. Third, they argue that a satisfactory degree of price competition can be secured in the former basing point industries through use of the uniform f.o.b. mill pricing system. Each of these points will be considered in turn.

The theory of natural evolution is indeed easy to demolish, for it is only a straw man. Those who adhere to the oligopolistic view do not claim that the basing point system came about automatically and impersonally. They claim only that it was not an artificial imposition, since the market characteristics of the steel industry and certain other industries make the emergence of a pricing system like the basing point system highly probable. Human intervention in the actual development of the system is not precluded.

Whether basing point systems are collusive devices is a question of

fact. The Supreme Court in the Cement case said: "We think that adequate findings of combination were made and that the findings have support in the evidence." The Seventh Circuit Court ruled similarly in the Ridgid Steel Conduit case. Users of the basing point system, however, have vigorously dissented. It is not necessary to decide here whether the courts were right or wrong. For, from the point of view of public policy, the real question is not whether there has or has not been collusion, but whether the mere elimination of collusion, if it exists, will produce a substantially different form of rivalry.

The foregoing analysis suggests that it will not, particularly if one's standard is near to the purely competitive. The incentive to discriminate and the further incentive to keep discrimination within certain bounds exist independently of any possible collusion and would continue to exist after it was ended. The basing point system, in short, only expresses and formalizes a type of price behavior which arises for reasons other than collusion. This is not to suggest that collusion is to be countenanced; it is only to suggest that its elimination, if it exists, would not be decisive. To change pricing policy in a way which makes sense economically one must change the market conditions which produced it.

The uniform f.o.b. pricing system requires that a seller receive the same mill nets on all sales; freight absorption is excluded. Therefore, each seller has a local monopoly in his freight advantage territory, which he can enlarge only by lowering his mill price. Proponents of this pricing method expect that it will lead to a substantially greater degree of price competition, because sellers are provided with a compelling incentive for reducing their plant prices; i.e., the expansion of sales territories in which they can have no rivals.

This reasoning ignores the realities of pricing under oligopoly; it erroneously assumes a one-to-one relationship between an incentive to cut prices and actual price cuts. The true situation would seem to be as follows: If business at the geographic margin is substantial, there is an incentive to cut prices to get it. However, the returns from this added business must be balanced against the lower returns on sales which could be made without a price cut. If the marginal sales are still worth making, then they are by the same token too lucrative to lose, and a price cut would probably be met. Other sellers might meet a price cut even if the marginal business was not lucrative, in order to prevent their customers from being placed at a disadvantage in competition with the customers of the price cutter. If for either reason a price cut is met, all sellers are worse off than before, including the original price cutter. The practical result is that price cuts are not made. As soon as a mutually satisfactory pattern of f.o.b. prices has been established, it tends to remain unchanged; a *de facto* market sharing agreement de-

velops. The likelihood of price cuts is therefore even less than under the basing point system. A base price cut by a single basing point seller makes freight absorption by his competitors more diffcult, but it does not bar them from entire portions of the market. Hence there is less pressure on competitors to meet it, and therefore a greater probability that it will be made.

The elimination of freight absorption is considered a salutary result by many, on the grounds that merely meeting a competitor's price is not really competition. We have seen, however, that competition in the steel industry is likely to take the form of freight absorption; that is, given the cost structure of the industry, both sales with and without freight absorption are competitive, each reflecting the different force and character of competition in different parts of the market. Since mill price reductions are not a real alternative to freight absorption, the prohibition of freight absorption involves a subtraction from competition and not an addition.

If the prohibition of conspiracy is beside the point, and the uniform f.o.b. mill pricing system undesirable, what is the appropriate alternative to the basing point system, if any? The answer lies in the reasons for which the basing point system was used. As we have seen, it produced certainty with respect to the structure of steel prices, and kept discrimination within certain bounds; it favored price meeting rather than price beating. The proper pricing alternative is surely one which puts back, so to speak, the uncertainties which the basing point removed and which lets competition, even including price discrimination, have the maximum possible effect on the prices paid by buyers.

The pricing method which best does these things combines features of both the basing point system and the uniform f.o.b. mill system. As with the uniform f.o.b. mill system, each seller is required to post a plant price and to sell f.o.b. at that price. Delivered sales are permitted, but they must include only the actual cost of the form of transportation selected by the buyer. As with the basing point system, sellers are permitted to absorb freight, but only if a competitor has quoted or can quote a lower price on the product type and size being offered. The last requirement forces sellers to make individual rather than collective decisions about freight absorption and prevents pricing from becoming completely routine. It also forces sellers to find out what their competitors are actually doing, and may lead to a more active, outgoing, and vigorous pricing policy.

Because sales under this method are made f.o.b. and because there is no longer a commonly accepted method for calculating delivered prices, exact prices at every point of delivery are no longer known in advance. It is more diffcult for a seller to know what prices he has to meet, and

more likely that he will beat rather than merely meet competing prices. It is also easier for buyers to play one seller off against the others.

Although this pricing method should produce a more effective type of price competition than the old basing point system, the difference will be in degree and not in kind. The plain fact is that rivalry in the steel industry and in similar industries is not likely to take the form of competition in price. The reason is not that conspiracy prevents it, or that steel producers are improperly motivated; it is rather that the conditions necessary for vigorous competition do not exist, as a matter of objective economic reality. Therefore, price competition of a substantial sort cannot be brought about through changes in pricing systems or through the artificial imposition of the symptoms of price competition. Unless and until the structural characteristics of the steel market are changed, if they can be, no tinkering with pricing systems will really pay off.

III

It would be very instructive if the preceding analysis could be tested against the performance of the steel industry since the elimination of basing point pricing in 1948 and the drawing up of the FTC steel order in 1951. Unfortunately, the period has been much too short; moreover, business was at such a high level for most of it that there was no particular pressure on prices. However, a brief look may be suggestive.

Very briefly, the FTC steel order prohibited producers from entering into any planned common course of action, understanding, or agreement, or from acting independently or otherwise so as knowingly to contribute to a planned common course of action, understanding, or agreement, to do the following: (1) fix the price of steel or any element thereof; (2) compile, circulate, and use lists of base prices and extra charges; (3) compile or circulate lists of freight rate factors; (4) adopt special pricing practices for particular classes of customers; (5) sell steel at prices calculated in accordance with a formula which produces identical delivered prices or which establishes a fixed relationship among prices; (6) fail to sell f.o.b.

In addition, the order provided that the FTC would not consider uniformity of price "alone and without more" as showing a violation of the law, and that it would not prohibit freight absorption as such "when innocently and independently pursued, regularly or otherwise, with the result of promoting competition." Thus the order, in its essentials, conforms quite closely to the pricing method suggested above as an alternative to the basing point system.

After being at or near capacity for a number of years, steel operating rates began to fall off in the fall of 1953. The period since then is

therefore the most significant from our point of view. The *Iron Age* reported, as early as September, 1953, that a few companies were again absorbing freight. In October, most companies formally announced that they would do so. According to the *Iron Age*, the policy was to consider each case individually, and to absorb freight only if there was evidence that a competitor was quoting lower prices. Producers were not offering to absorb freight to all buyers at a given locality, but only to those whose business was particularly attractive. The producers were planning to continue f.o.b. prices, and were not returning to the old basing point system. In December, the *Iron Age* reported that producers were going to a lot of trouble to make sure that competition actually existed before they absorbed freight, including a check to determine that their rivals actually produced the type and size in question. In July, 1954, the *Iron Age* reported that freight absorption might cost as much as 70 million dollars in 1954, or an average of $.75 to $1.00 per ton and that it had become a routine part of the business. It is clear, therefore, that freight absorption has been renewed on a wide front. There is no evidence, however, of the systematic, routine meeting of competitors' prices which characterized the old basing point system. There is also no evidence of price beating rather than price meeting or of a general increase in the forces of competition over the basing point days.

There have also been interesting developments in the transportation of steel. Under the basing point system, delivered prices were made up of base prices plus all rail freight, regardless of the method of transportation used. In practice, rail transportation, the most costly form, was used almost exclusively. A marked change began with the introduction of f.o.b. pricing in 1948; trucks, in particular, were used with increasing frequency. Figures for 1953, compiled by the *Iron Age*, show how far the trend has gone: on an over-all basis, trucks carried 53 per cent of total steel shipments, the railroads 44 per cent, and barges 3 per cent. Hence, the end of basing point pricing has clearly resulted in the use of varied forms of transportation. Since the cost of the form actually used now determines the price at the point of delivery and since the determination of freight costs is tricky even for a single form of transportation, uncertainty about competitors' prices has been substantially increased.

The steel industry's recent experience is inconclusive for the determining whether there will be a greater degree of price competition without the basing point system. No real answer will be possible until a number of years have passed and the industry has experienced varying demand conditions. It is significant, however, that the resumption of freight absorption almost immediately followed the drop in operating

rates. The pressure to expand sales when capacity is not fully utilized is clearly an important and ubiquitous force. It is also significant that there has been a major shift to forms of transportation ignored under the basing point system and that the freight absorption which has taken place has been on an individual and not a systematic basis. There have been some beneficial results, therefore, from the elimination of the basing point system. Perhaps the future will see more.

DISCUSSION

Walter Adams: Mr. Whitney's study of the movie decree is comprehensive and competent. The facts presented are up to date and accurate. Nevertheless, I disagree with Mr. Whitney's general emphasis and his unduly pessimistic conclusion.

The purpose of an antitrust decree is to "effectively pry open to competition a market that has been closed by defendants' illegal restraints." Such a decree cannot, however, in and of itself, effectuate a permanent change in industry structure or practices. All it can do is to break up or render impotent, for the time being, the monopoly power which violates the law. All it can do is to remove temporarily some of the artificial restraints which in the past had limited the freedom of competitors and customers. The test of a decree's effectiveness is not that it minimizes complaints by vested interests nor that it protects any group from economic hardship or inconvenience. The test is whether substantial competition has been restored to the market place; whether consumers have a wider range of choice; and whether competitors have more freedom and potential competitors greater opportunity than before. With this standard in mind—and remembering that the last of the movie decrees took final effect only last fall—my appraisal is less pessimistic than Mr. Whitney's.

First, it seems clear that seldom (with the exception of World War II) have independent producers been as successful as since the divorcement of the Big Five. With the vertical control over choice exhibition outlets broken, independents have enjoyed an unparalleled opportunity to market a quality product. Moreover, here is one case where a comprehensive divorcement decree is not likely to impede technological progress. As Professor Hellmuth has pointed out, practically all major innovations in the industry—the star system, multireel features, sound, and now three-dimensional films—have been made by what were minor companies at the time. Here is one case where integrated size has not given us better things for better living through research.

Second, as Mr. Whitney concedes, the public has benefited from an improvement in film quality. Though admission prices have gone up, the consumer probably gets more picture quality per dollar today than he did in 1948. In addition, he has more first-run choices than ever before. Finally, not least among his blessings is the greater frequency and wider distribution of foreign films—the superb sophistication of Alec Guinness and the unequalled dramatic talent of, say, Gina Lollobrigida. After a moment's reflection, Mr. Whitney will, I am sure, concede this point.

Third, the exhibitors have no doubt suffered. But it seems to me that neighborhood theaters, relying primarily on a steady stream of mediocre films, would have been injured by TV in any event. It is true, of course, that the divorcement decree destroyed the umbrella which the old monopoly system spread over the small fry. It is true that the decree (as well as the advent of TV) accentuated the difference in reward between good pictures and bad.

It is true that these changes were a painful experience for many exhibitors. This does not mean, however, that the changes were bad or against the public interest.

Finally, and probably most important, is a point Mr. Whitney treats only casually and nonchalantly; viz., the extent to which the government itself has undermined the effectiveness of the antitrust decree. In 1953, the Federal Communications Commission approved the merger of Paramount Theaters and American Broadcasting Company, recognizing the combination's right to produce movies for TV exhibition. The Commission also acquiesced in the control by Paramount Pictures of DuMont TV—the fourth largest network in the country. If this development foreshadows a general trend in the industry, we may—as Professor Hellmuth points out—be witnessing the vertical reintegration of the Big Five—the very integration which the antitrust suit sought to destory. Obviously, horizontal mergers between movie exhibitors and TV chains would vitiate the stimulus of interindustry competition. Obviously, vertical mergers of motion picture producers and TV exhibitors would revive the very industry structure which entailed a maze of trade restraints. This, rather than the antitrust decree, is a cause for concern.

The recent action of the FCC has, I think, demonstrated once again that government is not an agent of countervailing power; that, instead, government often supports the economic forces which breed monopoly; that the government's exercise of administrative or regulatory powers often creates the very restraints which antitrust is subsequently required to dissolve. In short, here we may have a case where government approves what the antitrust laws are designed to prevent—where government helps remake an industry in the image of the cartel.

Samuel M. Loescher: Mr. Marengo is indeed pessimistic about the prospects of increasing effective (price) competition in the steel industry by means of antitrust policy directed at trade practices. Rigidity in pricing is attributable primarily to the industry's structure. Therefore, he draws the conventional, and safe, academic conclusion that public policy should be directed at altering (if possible!) the structural characteristics of the steel market. Now most economists would probably subscribe to, and believe to be economically feasible, a policy of limited restructuring of the steel industry. But that extensive dissolution is a practical policy alternative is most unlikely. As Dean Edward Levi has reminded us ("A Two Level Antimonopoly Law," *Northwestern Law Review,* December, 1952, pages 567-568), the courts have yet to adopt a realistic percentage share test of illegal market control. Furthermore, in the unlikely event that the courts moved toward a percentage test, market control can be calculated only after a meaningful designation of the market, in terms of both geography and products. In adversary proceedings, arguments as to the market would represent no little war of containment.

As a consequence, unless we are to allow the quest for more effective competition in the steel industry to go by default, it will be necessary for public policy to concern itself with behavior and trade practices. Moreover, there are

important reasons for believing that an attack on trade practices offers opportunity for substantial improvement in terms of price behavior.

I should like to agree with the author that nondiscriminatory f.o.b. mill pricing does not offer the best alternative to the basing point system. But I cannot accept his conclusion that compulsory f.o.b. pricing would make for less price flexibility than the old basing point system. If nondiscrimination were the only practical policy alternative, I would readily cast my vote for f.o.b pricing for two reasons. First, the spatial distribution of sellers in the steel industry is such that the gain of important markets at the geographical margins by a firm which lowers its f.o.b. price is likely to be greater than the individual market losses suffered by the rival sellers. As a result, oligopolistic reckoning notwithstanding, some significant uncertainty exists as to whether all excluded rival sellers will retaliate. Such uncertainty differs markedly from the built-in automatic multiple-price leadership of the basing point system. Under the familiar formula, base price increases and decreases are bound to be met in the initiator's "natural" market, save for the effect of encouraging or discouraging access into this market to the rivals most distantly located. Secondly, geographical shifting demand, which we might call the Stiglerian effect, although less striking than in the cement industry, is fairly significant in steel since construction has recently been estimated to absorb 20 per cent of steel's output. Long-term as well as short-period peripatetic shifts in steel consumption should prevent a simple freezing of market shares based on stable intermill price differentials. Reconciling of conflicting interests without flagrant consultative collusion stretches too far the elastic possibilities of imperfect competition theory. However, there is something fairly definite and orderly about compulsory f.o.b. pricing systems which suggests that geographical pricing practices incorporating even greater uncertainties should be sought.

I agree with Mr. Marengo when he emphasizes that freight absorbing delivered prices were an inevitable quasi-competitive marketing technique in industries with market structures such as steel. I also agree with his emphasizing the distinction between the price policy restraining competition which an industry with a few sellers might wish to adopt and the mechanism—a system or formula—which could guarantee success in the price policy so long as each seller had merely the will to adhere to it. Mr. Marengo, however, believes that all rail delivered prices and the circulation of freight books were the essential mechanical elements of the basing point system. These elements permitted rival sellers routinely to meet and avoid the fears of beating competition when absorbing freight.

It seems to me that one's analysis of formula pricing must be carried further, and will be improved if one emphasizes imperfect collusion in place of the more conventional dichotomy of collusion and oligopolistic imperfect competition. In every basing point system which I have studied, there has always been the refusal on the part of sellers to offer to buyers located in each mill's "natural" market (in which freight is not absorbed) an option of a bona fide f.o.b. mill price. Bona fide f.o.b. mill prices are considered to be the posted base mill prices without fictitious premiums. Given bona fide f.o.b.

mill prices, several local buyers might wish to purchase from the mill and transport the product in the buyer's private, leased, or contract trucks. With uncontrolled trucking, there are no published transportation charges. More distant sellers find it not only difficult but virtually impossible to determine the destination cost of steel to the buyer. At least within the range where trucking is economically feasible, formula destination prices could not be ascertained. Therefore, a freight absorbing distant mill which seeks to penetrate many of his rivals' natural markets cannot meet competition, but on the contrary will probably win such patronage only through an inadvertent beating of competition. A distant seller either partakes in unsystematic pricing or he declines to penetrate.

The steel industry in 1935, after the demise of the NRA, simultaneously and arbitrarily imposed on truck shipments a surcharge equal to 35 per cent of the applicable rail freight. This action followed the passage of a resolution by the American Iron and Steel Institute. That such an action represented a collusive act seems unmistakable. Of course, given the fact that any basing point system involves profit reducing cross hauling suggests that the resulting collusion was imperfect. But by discouraging buyer's trucking, the formula of known destination prices was preserved, and achieved, if you will, effective collusion. Once trucking is eliminated or controlled by the seller (so that published transportation tariffs are made available), further overt collusion is unnecessary. The ability merely to meet competition is available to those who have the will to maintain the system.

Have the basing point decisions effectively altered trade practices in the steel industry? I believe the answer is "no"—and my reply applied especially to the period between September, 1953, and November, 1954, of operations substantially below capacity. I agree with Mr. Marengo that freight absorption during this latter period has been performed on an "individual" basis rather than routinely in accordance with a simple formula. But except for precluding the old practice of identical formula sealed bidding to state and local governments, the so-called "individual" meeting of competition still represents all the essential characteristics of a system for identical pricing. The only difference may be that in the absence of an organized distribution of freight books, and with the added presence of common carriers and sellers' controlled trucking, the verification of a much greater number of freight rates becomes a more complicated task. Errors of freight rate calculation may more frequently lead to some beating of competition.

There has been a transportation revolution in the steel industry in the postwar period as trucks now haul the majority of total steel shipments. The basing point decisions have been partly responsible for the change and a more rational and economical use of the nation's transportation facilities has resulted. However, the major advent of trucking of steel products does not appear to have brought about, to the extent which might have been expected, the erosion of a freight formula for purposes of systematically meeting competition. Recently I made a survey of steel companies, to which seven major (million-plus ingot ton capacity) and eight minor firms responded. It indicated that the overwhelming proportion of trucked steel products move

to buyers in common carriers, supplemented by the seller's contract, leased, and private carriers. In each of these cases of controlled trucking, tariffs are either filed with public commissions or the steel producers are able to publish truck rates to sundry destinations. With the exception of two minor steel concerns, the responding steel companies referred to transportation in buyers' contract, leased, or private trucks as being "small, relatively small, or negligible." I have been unable to determine as of this date if some practice may have been adopted so as to discourage transportation in trucks controlled by the buyers. Familiarity with controlled trucking in the cement industry, however, leads me to suspect that bona fide f.o.b. prices are not being offered.

An evaluation must necessarily follow concerning the FTC's cease and desist order which prohibits failure to sell on an f.o.b. basis. I believe that the Commission's order against the iron and steel industry is highly defective.

Although the FTC's findings of facts do not find conspiracy (implicit or otherwise), the initial complaint and the subsequent consent order are clearly phrased in the language of conspiracy. And even more important, the FTC appears to have blundered in failing to prohibit each respondent individually from quoting fictitious f.o.b. prices and refusing delivery to buyers who wish to use their own form of transportation.

That the Commission failed to draft an effective trade practice order for the steel industry is strikingly illustrated by an unsuccessful attempt of one major steel company to sponsor an industry-wide delivered zone pricing system for steel. In December, 1953, Republic Steel initiated for hot-rolled carbon bars a delivered price, based on an average freight factor from its mills, for each of 1,481 counties it normally served. That bona fide f.o.b. prices were not to be offered was apparent in Republic's statement that the "consumers in switching areas adjacent to mills have the option of free delivery or can come into the mill and pick up the steel themselves" at an f.o.b. price including phantom freight. Republic, at the time, also announced that it still intended to meet local competition on an "individual" basis. That Republic was taking the leadership and hoping that other steel companies would accept the invitation to establish an all-delivered zone pricing system can be inferred from Republic's October, 1954, announcement. This stated that Republic was abandoning its zone system because other firms failed to follow. Meeting of competition under a county zone system of delivered prices would indeed have been vastly more definite than even the old basing point system. Other firms in the industry may have feared a general adoption of the zone system because of the vulnerable elements of phantom freight which would have been inherent in single deliverd prices for entire counties. Moreover, systematic geographical price discrimination on an individual basis had been fairly satisfactory.

Some increase in effective competition in the steel industry, even in the absence of a major restructuring, would appear to be feasible. However, the current model of meeting competition on an individual basis, albeit an improvement over the older simplified base-price-plus-rail-freight formula, represents less of an innovation than can reasonably be expected of a progressive antitrust policy.

JAMES H. STAUSS: In his lucid analysis of the metal container industry, Professor McKie emphasized the economic consequences of the American Can case of 1950. Among other judgments, he said that "the gross structure of the industry has not changed very much and probably will not change much in the future." He also concluded, in view of the impact of the decree, that "a forecast of workable competition appears to be justified." I shall comment on these two judgments, and I shall do this in terms of market structure, performance standards, and mutually completing aspects of structure and performance.

In terms of structure, my impression is that the following situation prevails in the metal container industry:

1. The industry is, and probably will be, characterized by "fewness of sellers," although a significant number of concerns have little spots of business after the large bulk of the industry is accounted for with respect to sales.

2. The industry has, and probably will continue to have, two "large" sellers sharing most of the industry's output and several "small" sellers sharing most of the remainder. A similar generalization fits the realities of separate markets, regionally or locally.

3. The industry is free of cartelization, and it is prudent to expect a continued absence of collusion.

4. The impediments to entry are not, and probably will not be, seriously formidable insofar as patents and capital requirements are concerned. On the other hand, ease of entry is not characteristic of the industry; that is, the established leaders have, or are thought to have, critical advantages in the management and unified servicing of multiplant enterprise, in the quantity purchasing of raw materials, in the financing and carrying out of research and product improvement, in the possession of marketing know-how and historic patronage, and in the waging of non-price rivalry. It is not clear that ease of entry will be characteristic of the industry, even though the 1950 decree knocked out a number of formidable exclusionary devices, especially cumulative volume discounts, long-term requirements contracts, ties between the leasing of closing machines and the sale of cans, and supports for the dependence of can buyers on the closing machines of American and Continental. These devices, representing customers tied to the established can suppliers, once protected the major market shares. Yet, now that the exclusionary devices are temporarily or permanently outlawed, only certain buyers of cans offer a significant threat of entry through the manufacture of their own containers. It is not clear that this threat will be a decisive disciplinary force acting on the established leaders.

5. The structural conditions, which are oligopolistic, compound themselves into alternative sources of supply available to buyers. From one point of view, these alternative sources of supply are "enabling conditions" making it possible for buyers to select their sellers. In consequence of the American Can case of 1950, these enabling conditions were strengthened, because tying arrangements were broken, dependence on closing-machine leases was greatly reduced, and requirements contracts were shortened. The canning industry, much of which is effectively competitive, is more independent than before,

and it has an increased opportunity for choice among container manufacturers. From another point of view, however, the alternative sources of supply are "limiting" conditions that restrict in some measure the range of decisions and actions practically available to each container manufacturer.

As I see this structural situation, the two pertinent questions are these: (1) Are the buyers' enabling conditions equivalent to "genuine" or "real" alternatives of supply—in terms of downward pressures on price, upward pressures on product improvement, and opportunity to avoid price lethargy and strictly parallel action by sellers? (2) Are the sellers' limiting conditions equivalent to "genuine" or "real" disciplinary restrictions—in terms of a rivalry that compels the sellers to participate in downward pressures on costs and prices and in upward pressures on product improvement? The structural situation, present and prospective, in regard to fewness of sellers, dominant market shares, and impediments to entry, does not appear to represent "workable competition." However, this competition could emerge in a mixture of effective intraindustry rivalry, effective intercommodity competition, and successful meeting of performance standards applicable to the metal container industry.

In terms of performance, my impression is that the uncertainties are too great to justify a forecast of workable competition. I accept Professor McKie's judgment that small sellers reaching for enlarged market shares, as well as certain buyers threatening backward integration, will enhance price rivalry to some extent. I also agree that technological and service rivalry will act as a disciplinary process. On the other hand, the established leaders will probably safeguard their dominant shares through their superiorities in waging this technological and service rivalry. The downward pressures on price may not pervade the bulk of most markets, and parallel—and perhaps rigid—pricing may be common practice. It is too early, moreover, to estimate the future strength of intercommodity competition from fiber, plastic, aluminum, and glass containers, and it is not clear that the metal container industry would try to protect itself by reduced-price measures. Finally, a forecast of workable competition in the metal container industry must depend on how well the industry is meeting, and how well it is expected to meet, standards of performance in terms such as reducing costs, making price reductions pursuant to cost reductions, and keeping down its level of profits.

Although I believe that a forecast of workable competition is not now justified, I agree that the American Can case of 1950 has improved the economic health of the metal container industry. The case is notable, too, from the standpoint of the unprecedented control over business practices and dealings that the court decreed, particularly with respect to compulsory licensing of patents and compulsory extension of technological information. I suggest, however, that the District Court's interpretation of antitrust law in this case may be deceptive; that is, economists may conclude that economic power was cut with a sharp knife. As I read the opinion and the ruling, the emphasis is on "abuses" and on evidence of intent. In other words, antitrust law may prevent and suppress certain arrangements and behavior that "real" competitors do not engage in; but antitrust law, in its present state of legisla-

tion and adjudication, does not compel the anatomy and functions of workable competition. It does not prevent and suppress the anatomy and functions of large size, monopoly, oligopoly, or concentration, if any one of these phenomena simply exhibits economic power and only violates workable competition. Thus, in the American Can case of 1950, the district judge said, "I am not willing to burn a cathedral down because someone committed a sin therein."

RESEARCH ON THE BUSINESS FIRM

LIMITS TO THE GROWTH AND SIZE OF FIRMS*

By EDITH PENROSE
Johns Hopkins University

I. *Size Versus Growth*

There are two approaches to the question of the size of firms. The traditional approach attempts to explain size in terms of the balance of advantages and disadvantages of being a particular size. Another approach emphasizes the process of growth and treats size as a more or less incidental result of a continuous on-going or "unfolding" process. The first—which I may call the size approach—has found its exponents among those who stress the economies and diseconomies of large-scale production and among those who stress the monopolistic advantages and economic power of bigness. The second—the growth approach—has so far been expounded in any systematic form only by the "biological economists"—by those who view firms as organisms and conclude that they grow like organisms. That variant of the growth approach leaves no room for human motivation and conscious human decision and I think should be rejected on that ground. (See "Biological Analogies in the Theory of the Firm," *American Economic Review,* December, 1952, pages 804-819.)

I want here to suggest an alternative growth approach which, in common with the biological variant, insists that a predisposition to grow is inherent in the very nature of firms, but which, in contrast, makes growth depend on human motivation—in the usual case on the businessman's search for profits.

The analysis presented in this paper is most applicable to business enterprise in the form of corporations. It will be concerned only with industrial firms and only with internal growth. Growth by merger will not be considered. While it is true that merger in the broadest sense has been of great importance in the growth of firms—and of greater real significance, perhaps, than statistics of the percentage growth by merger for different firms would indicate—merger by no means accounts (at least in recent times) for even the major part of the growth of most large firms, as the studies of Weston, Schroeder, and others have shown.[1] Furthermore, I think it likely that growth can proceed just as

* I am particularly indebted to Carl Christ, Evsey Domar, and Fritz Machlup for helpful criticism of this paper.

[1] Fred J. Weston, *The Role of Mergers in the Growth of Large Firms* (University of California Press, 1953); Gertrude G. Schroeder, *The Growth of Major Steel Companies, 1900-1950* (Johns Hopkins Press, 1953).

far with or without merger, though not at the same rate. To show this, I want to consider growth without merger.

II. *Causes of and Limits to the Growth of Firms*

First, I shall be concerned with the causes of and limits to the growth of firms. It is convenient to divide the relevant considerations into two categories: those that are external to the firm and those that arise from the nature of the firm itself. For example, difficulties in obtaining capital or the existence of unfavorable demand conditions have been used to explain why some firms fail to grow, or disappear entirely. Conversely, a growing economy or changes in technology increasing the so-called "optimum size" of firms have often been given as explanations of continuous expansion. Such things do indeed have important effects on the rate of growth of firms. They are external factors which influence the speed and direction of growth but the importance of which cannot be fully understood without an examination of the nature of the firm itself. The more interesting question, to me, is whether there is anything in the nature of the economic institution we call a firm that induces growth, makes it possible, yet limits the rate of growth. This is the problem I want to discuss here: the internal incentives to and limits on growth—a theory of the growth of firms that does not relate to fortuitous external events.

The Problem of Planning. To begin with, let me stress an obvious fact, but a fact of central importance for the growth of firms: Successful expansion must, in the usual case, be preceded by planning on the part of the firm. Firms do not just grow automatically, but in response to human decisions. And if firms act on the basis of plans, it follows that they have some degree of confidence in these plans. The question therefore arises how a firm obtains the required degree of confidence. Unless it is assumed that knowledge is perfect and that uncertainty is absent—assumptions that are useless and inappropriate in this context—it is clear that a body of knowledge sufficient to sustain rational plans for action must be developed within the firm. What may broadly be characterized as managerial research will be necessary for the purpose. Consequently, some part of the managerial and entrepreneurial services of the firm must be available to work on the requisite plans whenever expansion is considered.

The fact that expansion must be preceded by research and planning, on the one hand limits the amount of expansion that can be undertaken at any given time and on the other hand permits continuous expansion through time. I propose to show that expansion itself tends to create opportunities for further expansion—opportunities that did not exist before the expansion was undertaken—and this for two reasons. First,

the execution of any plan for expansion will tend to cause a firm to acquire resources which cannot be fully used at the level of production contemplated by the plan, and such unused services will remain available to the firm after the expansion is completed. Second, planning itself and the execution of a plan will tend to absorb managerial services which will not be required in the operation of the enlarged concern and which therefore will be released upon completion of the expansion program, while at the same time the services that the firm's management is capable of rendering will tend to increase between the time when the plan is made and the time when its execution is completed.

The Continuing Availability of Unused Productive Services. Let us begin with the problem of using fully all services acquired. This raises two separate questions: Why does a firm acquire services it does not need? And why, if it acquires them, does it not use (or sell) them?

The answer to the first question involves a familiar analysis with an extended application. As long ago as 1832, Babbage set forth the principle that the most efficient output for any establishment will be that which uses a "direct multiple" of the "number of processes into which it is advantageous to divide" the production of an article. This is essentially what Austin Robinson a hundred years later called the "balance of processes"[2] and what Sargent Florence calls the "principle of multiples."[3] If a collection of indivisible productive resources is to be fully used, the minimum level of output at which the firm must produce must correspond to the least common multiple of the various maximum outputs obtainable from the smallest unit in which each type of resource can be acquired. The principle has usually, if not always, been applied only to machines, and even in this case Robinson has suggested that it may be necessary to plan production on a very large scale in order to use all machines at their most efficient level of operation. When, however, the full range of resources used in any firm is considered, including management, engineering, and even research personnel, as well as the minimum resources needed to sell the product, it is clear that this least common multiple may involve an enormously large output. This output will tend to be greater the larger the variety of resources and the more diverse the units in which they come. A firm would have to produce on a vast scale if it were to use fully the services of all the resources required for much smaller levels of output.

Obviously the output that will utilize most efficiently all of the firm's resources can only be reached if there is no limit short of this output on the supply of any one of them or on the market for the product. If

[2] E. A. G. Robinson, *The Structure of Competitive Industry* (Harcourt, Brace, 1932), pp. 31-33.

[3] P. Sargent Florence, *The Logic of Industrial Organization* (London: Kegan Paul, 1933), pp. 18-20.

there is any fixed factor in the productive operations of a firm, it will only be by chance that the firm will be able so to organize its resources that all of them will be fully used. The firm will, to be sure, use the services for which its resources were acquired to the fullest extent consistent with the lowest-cost combination of these resources for the amount and kinds of product it has decided to produce, but there is no reason to expect that it would be possible to make them come out even, so to speak. If the limiting factor were removed, additional services from some of the resources already acquired by the firm in the course of its operations would be available at no extra cost to the firm.

In addition, of course, most productive resources, including labor and managerial personnel, are capable of being used in many different ways and for many different purposes. Hence a firm in acquiring resources for particular purposes—to render particular services—also acquires a range of potential productive services, most of which will remain unused. This multiple serviceability of resources often gives firms a flexibility in a changing and uncertain environment which may become of great importance in determining the direction of growth.

Limits on the Supply of Managerial Services. There is one type of productive service which, by its very nature, is available to a firm in only limited amounts. This is the service of personnel, in particular, of management, with experience within the firm. Even if all other resources, that is, factors of production as available in the market, including the best managerial personnel, were in perfectly elastic supply, executives with experience within any given firm can only be found within that firm. The question, therefore, arises whether what I might call internally experienced managerial services are a necessary input in the process of expansion. It would seem so. Both general reasoning and discussions with businessmen confirm the hypothesis that a firm would never have a high degree of confidence in any extensive plan for expansion drawn up and executed exclusively by men with no experience within the firm itself.

There is little doubt that experience in a given environment does increase the ability of individuals to deal effectively with that environment, to anticipate and provide for circumstances they might otherwise have overlooked, and, in particular, to use other men to better advantage. This does not mean that indefinitely large plans for expansion cannot be made by any group, no matter how small or inexperienced, but only that such plans are apt to be less workable or reliable according as the scope of the plans increases in relation to the number of people with the requisite experience. To the degree that internally experienced personnel are not available, the firm (that is, the existing executive group) is likely to have less confidence in its ability successfully to

execute an expansion program. Management consultants, industrial engineering consultants, and similar advisory groups undoubtedly can render very important services. They reduce the extent to which a firm's own managerial resources must be left free for expansion purposes and widen the range of problems the firm can successfully handle. Nevertheless, not only the execution of plans for expansion but also the examination and approval of recommendations (after all, it takes time even to read reports let alone to pass on them) require a great deal of time and effort of the firm's own management.

Thus the making of expansion plans in which a firm has the requisite degree of confidence requires services which can only be produced within the firm. The production of these services requires time, and this limits the scope of a firm's expansion plans at any given time, but permits continuous extension of these plans through time. There are, of course, a number of restrictions on what can be achieved within any given period of time. Operations must often proceed in a certain sequence and many services required in expansion must be internally produced. These restrictions must be taken into consideration when the firm makes its expansion plans including its estimates of the time it will take before they are fully executed. But even to discover the size and composition of an optimum output under given circumstances requires an input of managerial and entrepreneurial services, some of which can be supplied only by individuals who have had experience within the firm. It is this restriction on the horizon of the firm, so to speak, that is significant from the point of view of its growth.

Let us imagine a case, for example, in which a firm has a fixed amount of experienced entrepreneurial services available for planning expansion; that the use of these in conjunction with other services will enable the firm to create a plan in which it has absolute confidence as to the outcome; and that for any more extensive expansion it will be necessary to fall back on the use of less experienced services, with the consequence that the firm will have less confidence in the outcome of actions undertaken in accordance with the plans. This lack of confidence can be looked upon as causing increasing costs—costs that are neither short run nor long run in the traditional sense. They are not short run, because plant and equipment are considered variable. They are not long run, because the considerations causing increasing costs are associated only with a temporary, though unavoidable, limit on the availability of services required for planning purposes. In both this and the traditional approach, managerial and entrepreneurial services are a fixed factor but costs are increasing, not because of some indefinable complexity due to size beyond the power of human beings to resolve even when organizational techniques are fully adjusted, but because of the limited

supply of experienced personnel at the time the firm plans its expansion. So long as executive resources can be added to a firm's staff, the supply of internally experienced management can be increased in the course of time, but the number of new executives that can be absorbed by a given firm in a given period and placed in situations from which they can gain the requisite experience is also limited by existing managerial resources and by the existing scale of operations of the firm. The rate at which the latter can be increased is precisely the problem that we are exploring.

In view of this limit on a firm's ability to extend indefinitely its plans for future operations, it is almost inconceivable that these plans can always, or even usually, be of such a scope that all of the firm's resources will be fully utilized. In general, there will always be services capable of being used in the same or in different lines of production but which are not so used because the firm could not plan extensively enough to use them. Such services are wasted for the time being. The type of resources for which this waste of service is most significant will depend on the nature of each particular firm. For some firms it may be machinery; for other firms the waste of administrative ability, executive talent, or the specialized connections of the sales force will be more important; for still others the significant waste may be of know-how, research-acquired knowledge, and engineering ability. That these last two are not an unimportant type of available, though unused, service is readily seen in the history of the expansion of individual firms in the modern world. The particular services that remain unused need not be of the same type as those that are actually used in current production; unused services are sometimes those of products and materials, skills and ideas, which are by-products of the primary productive activities of the firm.

Unused services are in themselves a challenge and an incentive to the ambitious entrepreneur. They are the excess services of resources which have been acquired and are needed in current operations; they are available for further production at no extra cost to the firm. An increase in production of the existing products of the firm which uses these services would, other things being equal, enable the firm to produce at a lower average cost. Of course, if a firm overestimates this free element in costs and underestimates the costs of other services that will be required, particularly increases in overhead costs due to additional production, a mistake will be made. The danger of "creep"—imprudent expansion on the basis of existing unused services—has frequently been expounded by accountants and others. But this does not affect the validity of the argument presented here. (See, for example, Robert L. Dixon, "Creep," *Journal of Accountancy*, July, 1953, pages 48-55.)

If the services were used in the production of products new to the firm, a competitive advantage would obtain over firms not having this free or joint element in costs. In many cases, of course, the ability of a firm to use such services depends on increases in knowledge and improvements of technique. As a matter of fact, many inventions and technological advances can be directly traced to the desire of a firm to take advantage of already possessed services not used in current production. Sometimes the profitability of devoting available resources to the primary lines of production has been so great that exploitation of minor lines has for long periods been neglected. That all profitable opportunities for productive activity known and open to a firm are not exploited together need not be explained by limited supplies of capital or other resources. As the investigations of Heller have shown, limited managerial services are often stated by management itself to be the important restriction on expansion. (See Walter W. Heller, "The Anatomy of Business Decisions," *Harvard Business Review,* March, 1951, pages 95-103.)

The Release and Growth of Managerial Services. If the preceding argument be accepted and it be agreed that the supply of the services of experienced personnel will, other things being equal, limit the amount of expansion a firm can plan at any time, then it is evident that further expansion becomes possible if, after the expansion plans are executed, such services become available to an extent greater than is necessary to operate the expanded concern.

Any substantial expansion involves not only acquisition of new personnel but promotion and redistribution of the old. Not infrequently a new subdivision of managerial organization is effected and a further decentralization of managerial functions takes place. Such reorganization may be done all at once or gradually as the progressive execution of the expansion plans calls for it. But the point is that both the new men brought in and the existing personnel of the firm gain further experience. Insofar as the increase in the experience of the men concerned is necessary to the execution of the firm's plans and was taken into consideration when the plans were made, the newly available services will be absorbed in the process of creating and operating the expanded concern. But it is impossible that all such to-be-created services be anticipated and their utilization provided for, not only because they include the as yet unknown experience of the planners themselves, but also because the variety of the potential services is unpredictable and their creation extends into the indefinite future.

Whether in carrying out an expansion program all of the firm's personnel are fully used depends partly on the policy of the firm. Firms whose general policy is to devote some part of their executive personnel

to the planning of expansion will have this personnel available for new planning as soon as any given plan is completed. At the other extreme, a firm's position may be such that those who make the plans also execute them and are therefore unable to devote time to additional planning until current plans are fully in operation. This policy is likely to be adopted of necessity by small and new firms whose executive staff is not very large. Nevertheless, once expansion has been completed and the operation of the firm fully geared to the new level of activity, additional productive services will be both created and released to provide the basis for further expansion.

They will be created because all personnel of the firm will gain additional experience as time passes. They will be released because as the range of services the managerial staff can perform increases, the new services will not be fully absorbed in the existing managerial tasks. Not only is there likely to be a generalized improvement in skill and efficiency but also the development of new and specialized services. When men have become used to working in a particular firm or with a particular group of other men in a firm, they become individually and as a group more valuable to the firm because the range of services they can render is enhanced by their knowledge of their fellow workers, of the methods of the firm, of the best way of doing things in the particular set of circumstances in which they are working. Individuals taking over executive functions new to them—either because the firm has added new functions or because the men are in new jobs—will run into difficulties and make mistakes merely because of the relative unfamiliarity of their work. When these individuals become more familiar with their work and succeed in integrating themselves into the organization under their control, not only will the effort required of them be reduced, but the range of services they are capable of rendering will be increased through experience. Both processes leave a residue of certain types of unused services in the wake of an expansion program.

The unused services thus created do not ordinarily exist in the visible form of idle man-hours but in the concealed form of unused abilities. The more complete use of the services of any given individual is supposed to be made possible by the process of promotion. Just as machinery after a point becomes less valuable and is "down-graded," so managerial resources may become more valuable and be "promoted." That promotion does not take care of all the increase in services that becomes available is the common experience of many firms in periods when growth is slow. Pressure from younger executives for advancement sometimes even creates for the firm a problem of maintaining the morale of personnel and cannot be entirely explained by the hypothesis that individuals tend to overestimate their own ability.

So far, managerial services have been treated as though they formed a pool of services differentiated only by the experience of the people rendering them. We have begged the question of the type of managerial services required to enable a firm to plan effectively and operate efficiently on an ever increasing scale. If the problems of adapting to rapidly changing external conditions are ignored, the simplest function of management is that of co-ordinating everyday operating activity within a given administrative framework, coping with minor problems, and improving existing ways of doing the same things. Growth requires initiative and imagination and thus a type of service different from that of the routine manager. The simplest type of initiating service is called for when expansion takes the form of increasing production of the products already being produced. Here management need only use on a wider scale the specialized knowledge it has already acquired. The managerial services available may be highly specific to the firm's existing products, but this makes it all the easier to expand as unused services develop, provided that additional goods can be sold at profitable prices. The analysis of this type of expansion falls within the framework of the conventional theory of the firm. The firm will expand the output of its products up to the point at which the increment in total costs equals the increment in total revenue, which, in the absence of diseconomies of scale, will be set by the well-known limitations on demand. This is familiar analysis and need not be elaborated.

The Utilization of Productive Services and Limits on Demand. The emphasis on demand as a restriction on the output of a firm arises because in the traditional theory of the firm, the firm is usually defined with reference to a given product. The theory of the firm serves primarily as a foundation for a general theory of price and output and hence is concerned with products rather than with the analysis of the firm as a many-sided economic institution. Once it is recognized that, in principle, the market of a firm in the wider sense is restricted only if the kinds of product it can produce are for some reasons limited, then it becomes clear that the flexibility and versatility of its own resources are the important factors governing the possibilities of its expansion. So long as there are profitable production opportunities open anywhere in the economy, a firm can take advantage of them if its resources are versatile—in particular, if its management is imaginative, flexible, and ambitious.

There are many examples of firms with vigorous and creative management who have substantially altered their range of products, sometimes completely abandoning their original lines and expanding their total output in spite of unfavorable demand conditions for their original products. There are, of course, many examples of other firms which

were not able to make the required adjustments. In such cases, failure to grow is often incorrectly attributed to demand conditions rather than to the limited nature of entrepreneurial resources.

There is not time here to examine this problem in more detail. Insofar as a firm is organized to produce only a given range of products, any limitations on the market for those products will prevent the firm from expanding the production of them. This is likely to mean that the firm will be unable to use fully its productive resources. A versatile type of executive service is needed if expansion requires major efforts on the part of the firm to develop new markets or entails branching out into new lines of production. Here the imaginative effort—the sense of timing, the instinctive recognition of what will catch on or how to make it catch on—becomes of overwhelming importance. These services are not likely to be equally available to all firms. For those that have them, however, a wider range of investment opportunities lies open than to firms with a less versatile type of management.

The most effective restriction on the versatility of executive services is that which stems from a lack of interest in experimenting or a lack of confidence in dealing with new and alien lines of activity. I say that this is the most effective restriction because mere specialization of managerial knowledge and ability is not itself a serious bar to a firm's branching out into new lines of activity if existing executives are sufficiently interested and confident to bring into the firm people possessing other relevant knowledge and ability. But it often happens that the horizon of management is extremely limited, particularly in smaller firms. Content with doing a good job in his own field, the small entrepreneur may never even consider the wider possibilities that would lie within his reach if only he raised his head to see them. If occasionally he gets a glimpse of them, he may lack the daring or the ambition to reach for them, although he may be an ambitious, efficient, and successful producer in his chosen field. Specificity of managerial resources means that some of the managerial services most essential for expansion are not available to the firm even though other managerial services essential for efficient operation in a particular field are fully available.

It is not helpful to dismiss this lack of vision, of confidence, or of experimenting ambition as an example of a failure to attempt to maximize profits, for they are intimately connected with the nature of managerial ability itself and must be reckoned as a limitation on the supply of specific types of productive services. After all, even a preliminary investigation into the possible profitability of any particular type of expansion presupposes a prior decision as to the allocation of managerial services between normal operations and the extension of these operations—a decision which, by its very nature, cannot in the

first instance be the result of a careful analysis of anticipated costs and revenues, since before such an analysis is undertaken the decision that it should be undertaken must be made. Whether such a decision is made at all is often a matter of temperament.

III. *Are There Limits to the Size of Firms?*

The managerial limits to growth discussed above are rather different from the type of limit on the supply of managerial services that is implicit in the traditional theory of the firm. There it is assumed both that the factors of production are in perfectly elastic supply and that the long-run average costs will at some point start rising—a situation which fundamentally can only be due to the quality of managerial services. The chief difference lies in the fact that imagination and ideas are not confined by time and space while the administrative activities of a single individual must be so confined. There is no known limit to the former. But there is to the latter, and from this it has been deduced that there must be a size of firm beyond which the services required for its efficient operation simply cannot be supplied by mortal men. This deduction is frequently stated as if it were an empirically established fact. The complexity of structure and the scope of activity are believed to become such that even the minimum decisions required of the chief executives in order to ensure the requisite degree of co-ordination are so difficult or so numerous that the firm must suffer in efficiency. Costs of production would therefore be greater in very large firms than in smaller firms—the so-called "diseconomies of scale" would overshadow all economies.

The planning of appropriate changes in the administrative organization of a firm is part of the planning of an expansion program. To some extent the kind of services necessary to effect this type of reorganican be hired. Just as techniques of production appropriate to large-scale operations are known and can be adopted from the outside, as it were, so known techniques of administration can be learned from the outside. Changing organization as a firm grows is very largely a progressive decentralization of authority. By its very nature, decentralization of this type cannot precede to any significant extent the expansion of the firm but must develop more or less simultaneously with it. Some firms may be incapable of effecting the appropriate administrative reorganization—for example, the existing executives may be unwilling to relinquish any of their personal control. These firms will find themselves unable to operate efficiently on a larger scale and will run into trouble as they attempt to expand. While some executives may be insufficiently used, others will be overworked, presenting a truly fixed factor, and diminishing returns will proceed with a vengeance.

We do not know how effective the decentralization of authority can be as a means of keeping costs per unit of output from rising as a firm expands. Reliable empirical evidence does not exist and all studies of the matter are inconclusive, but there is no evidence that a large decentralized concern requires supermen to run it. It does require more men who are competent to make high-level business decisions and who have had experience with the particular kinds of problem with which the firm has to deal. Neither is there significant evidence that the ability to fill the higher administrative positions is excessively rare or that the demands on the men occupying these positions exceed their ability to cope with them effectively.

As to the problem of co-ordination, a strong case can be made for the proposition that as a firm increases in size and its various parts obtain a greater and greater degree of autonomy, the real issue is not whether the whole thing becomes unwieldy but whether it should properly be called a single firm in any economic sense. For many analytical purposes, we must treat some of the parts of the firm as having an independent existence, while for other purposes we must recognize the nature of their interdependence in the administrative structure. As administrative co-ordination becomes more tenuous with increasing size, efficiency becomes less a matter of expert co-ordination and more a matter of the efficient operation of virtually independent parts. It is common knowledge that one department of a single firm may be efficient while other departments are inefficient. Some department heads are good and some are bad. I suppose that if an inadequate manager is placed in charge of a department, this is, by definition, poor co-ordination on the part of some central authority. But it need not be looked on in this way. There are plenty of poor managers in the business world—in responsible positions, too—and the large firms undoubtedly get some of them.

Co-ordination is relevant to efficiency only insofar as co-ordination is required and is attempted. That central control can be dispensed with over wide areas has surely been amply demonstrated by many large firms in the present-day economy, and that the end is not yet in sight is generally admitted. Neither the conception of a fixed factor nor the analysis of the diseconomies of scale is relevant in these circumstances. In the process of growth the "organism" radically changes its form; the firm becomes less "organic" and, indeed, less of a "firm" in the pristine economic sense.

This suggests an interesting paradox. The growth of firms may be consistent with the most efficient use of society's resources; the result of a past growth—the size attained at any time—may have no corresponding advantages. Each successive increment of growth may be

profitable to the firm and, if it uses otherwise underutilized resources, advantageous to society. *Ex ante,* the economist interested in resource allocation should approve. But once any increment of expansion is completed, the original justification for the expansion may fade into insignificance as new opportunities for growth develop and are acted upon. In this case, it would not follow that the large firm as a whole was any more efficient than its several parts would be if they were operating (and growing) quite independently. *Ex post,* the economist might disapprove.

MANAGERIAL MOTIVATION AND THE THEORY OF THE FIRM

C. Addison Hickman
North Carolina State College

This paper is essentially a report on a research project undertaken in collaboration with Dr. Manford Kuhn, social psychologist at the State University of Iowa. His part in the formulation of the conceptual apparatus abstracted herein and in the development of appropriate research techniques has been a major one. This project is now also being carried forth independently, as the testing and application get under way.

The paper will include: (1) a statement of the importance of the motivational assumption, especially to the theory of the firm; (2) a consideration of certain methological issues involved in examining such assumptions; (3) a short résumé of recent modifications of the assumed motivation; (4) a capsule description of "self" or "reference group" theory, as a promising general orientation from which to examine motivation; (5) a reformulation of motivation in terms of this theory; (6) a partial structuring in such terms of existing knowledge of the manager and his role; (7) suggested lines of research; and (8) possible research techniques.

Motivation has long been important, if often implicit, in economic analysis. In our particular economic system, featuring the business firm, managerial motivation is of special importance. Yet, few attempts have been made to systematically study managerial motivation, to isolate the factors that may influence and condition such motivation, and to bring economic motivation into the orbit of motivation generally.

The question of managerial motivation has thus far been handled primarily by establishing simple assumptions as crude first approximations. Thus most economic theory (especially the theory of the firm), the bulk of applied economic analysis, and much public policy assume profit maximization as the paramount goal of business and businessmen.

Establishing managerial motivation by assumption rather than by empirical means has become somewhat difficult to justify. Evidence of a variety of managerial goals continues to accumulate; our changing social and political institutions and attitudes have carried obvious motivational implications; and the economic theory and public policy predicated upon a single simple motivation have recently been subject to critical re-examination. Meanwhile, the concepts and researches

of social psychology, sociology, cultural anthropology, clinical pyschology, and psychiatry have made available new findings, approaches, and techniques relative to motivation.

Why has systematic study of managerial motivation been largely lacking, at least until very recently? One partial explanation has been reluctance on methodological grounds. Profit maximization is an assumption which is useful in constructing a model. To study this or any other assumed motivation, it is suggested, may involve a misunderstanding of the methodology of model building.

The realism or accuracy of the initial assumptions of the model is not, it is argued, what matters. It is the ultimate usefulness of the model that counts. If the model is not useful, then it is time to go back and tinker with the assumptions if need be, or to build another model. If the model is useful, however, then the assumptions matter little.

Assumptions, in short, should mostly not get in the way. They should be simple and clean cut in order to enable us to build models that are internally consistent and that give determinate results. A simple, unrealistic assumption might prove to be better and more useful than a realistic but complex or variable or ambiguous assumption. Thus many economists deny that recent modifications of the assumed motivation of profit maximization are necessarily a step forward.

One of the more explicit statements of the methodological case for such simple assumptions as profit maximization is found in a recent book, *A Textbook of Economic Theory*, by Alfred W. Stonier and Douglas C. Hague. They defend the assumption in these terms (pages 87-88):

> "Rationality" in the theory of the firm implies that the individual producer aims at earning the greatest possible money profits Now, no economist believes that all business men do, in fact, always maximise profits, nor does he necessarily believe that they should do so. But every economist wants his analysis of the individual firm to enable him to point to a single position where, in given conditions, the firm will be in equilibrium. It is therefore essential for him to make some assumption of this kind. If no such assumption were made, there would be no single equilibrium for the firm in any given circumstances. It would be very difficult to produce any definite explanation of the way firms fix output and prices at all

Later, Stonier and Hague also assert (page 499) that "the assumption of 'rationality' amongst business men seems a most reasonable one to make until empirical research provides a better hypothesis; and so far it has failed to provide one."

If such positions reduce to this assertion that profit maximization is the most plausible assumption yet available, one may register reservations or tentative disbelief, but the burden of proof is admittedly on the critic. If this position means that if two assumptions are equally plausible or if the relative plausibility is not known, the simpler assumption is to be preferred, again no serious quarrel can be sustained,

provided, of course, that the greater simplicity of the one does not discourage anyone from investigating relative plausibility.

Perhaps the most disturbing undertone in the Stonier-Hague argument is the suggestion that simplicity is a prime value. The difficulty here goes beyond the fact that determinativeness alone may not always serve predictive ends. There also seems to be a good deal of prejudging as to the degree of simplicity which may be found at the end of a trail of research.

Despite such methodological concerns, there has been a tremendous amount of effort devoted since World War II to the modification of the previously assumed motivation of the manager. Economic theorists, students of business organization and management, businessmen and their spokesmen, and a host of others have either tinkered with profit maximization or have proposed additional or alternative motives. Out of this welter of opinions certain tentative conclusions emerge: (1) There is still considerable support, among both scholars and businessmen, for the primacy of the profit motive. (2) There seems to be an increasing tendency for this motive to be translated into something longer run, broader, and less precisely defined than the classic concept. (3) Other motivations of an economic character, such as preservation of the firm or maintenance of the size and position of the firm, are held to be of major importance. (4) The so-called "noneconomic" motivations are now taken much more seriously, despite the evident difficulties involved in measurement. (5) The complexity and variability of motivation have been recognized and some hypotheses have been suggested.

Thus many have groped toward a reappraisal of managerial motivation and in the process have moved a long way from the traditional concept of profit maximization. Most of these analyses continue, however, to treat the manager as an autonomous, isolated individual rather than as a member of groups and a participant in a culture. There has also been little attempt to apply what is known about motivation per se or motivation in other sectors of human behavior to the economic realm. There has also been little or no interest in the use of data relevant to managerial motivation in the construction of a general theory of motivation.

There now appears to be available an approach which might allow the fruitful re-examination of managerial motivation. From what was long termed the symbolic interactional approach has come what is now increasingly referred to as "reference group" or "self" theory. A capsule description of this approach, with a few of the attendant definitions which are of special interest to us, might now be in order. We may conveniently divide this brief résumé of self-theory into two general parts: a consideration of the nature of the world of man's

experience and a consideration of the nature of the person himself.

For the self-theorist, human beings do not live in a universe the events and objects of which have intrinsic meaning for and bearing upon human experience and behavior. They live rather in a universe mediated to us through social definitions couched in language. The stimulus-response-oriented researcher, in one of those rare occasions in which he attempts to use human subjects, characteristically puts his "subject" in an experimental room which he describes as a "neutral situation" and then subjects him to a predetermined "stimulus." The self-theory-oriented researcher, adhering to the idea implicit in "four walls do not a prison make," takes the view that he does not know whether plain gray walls make a neutral situation unless he has the relevant attitudes of the participants. Nor, for that matter, does he know the objects which he is going to vary without getting the relevant definitions from his participants.

No objects or events have "intrinsic stimulus value" for human beings. Those concatenations of events which we think of as objects have become objects as a result of the structuring of language. We experience them and behave toward them not in terms of any essential nature they may have but in terms of their meanings which they have as a result of language.

To understand the nature of the person, understanding of status and role and how they are acquired is necessary. When a child is born into some specific family, he is also given a specific status and assigned a specific role. Statuses are the building blocks—the smallest units of which any social group is made. They are the various positions, quite apart from the individuals who occupy them, which constitute the structure of a group. Every status, thus considered as a position in a group, has inseparably bound up with it a function to be performed. We refer to this function as a role. A role, like its correlative status, is defined quite apart from the person who is performing it. A role is a prescription, a recipe, a socially expected plan of action. It is an accepted and sanctioned proper-thing-to-do, together with the proper-way-to-do-it.

Each status and role derives its significance from the total configuration of statuses and roles of which it is a constituent part. No status, no role means anything by itself. An individual learns to occupy a status and to play a role by learning not only the rights and duties of his status and the requisite behaviors of his role but also those of all the other persons in the group or social system of which this status and role are a part. He must not only behave in such a way that the expectations of others will be met, but he must also be able, reciprocally, to anticipate correctly their behaviors.

We must distinguish, at this point, between those groups of which we are officially and formally members (called "membership groups") and those groups with which we feel self-identified (termed "reference groups"). It is the latter—the reference groups—which contain our "significant others" whose members' judgments we take into account and by which we identify ourselves as social objects. We may be, for example, a Baptist, a father, and a civil engineer. Each of these as a reference group provides us with relevant norms which we have taken as our own to be applied in certain kinds of situations.

The crucial significance of the self as a social object is that it is the only common object in all of the widely varied situations in which we participate. As such, it comes to serve as the anchoring point from which to make judgments and subsequent plans of action toward the many other objects in each specific situation. There is nothing mystical about this self. It consists of the attitudes (plans of action) toward the self as an object. We may think of it as consisting of all the relevant answers the individual might make to the question, as he would apply it to himself, "Who am I?" There is no way to answer such a question except by referring to oneself as a member of the groups that he feels identify him; or by referring to social categories which his reference groups hold to be significant in identifying him; or, finally, by referring to evaluations of himself which hinge on norms held by his reference groups. In any of these events, his answers are attitudinal statements which are the best indices of what he will do in any situation.

In terms of such a general orientation, how does one approach motivation? Self-theory would first lead one to reject the proposition that motivation is either individual or biological. The idea that motivation is individual has led us to focus attention on the solitary person, at the expense of a consideration of group norms and expectations. The idea that motivation is biological has resulted in attention to neural and glandular matters to the veritable exclusion of symbols and communication. The two ideas combined have led us to attend to ontogenetic sequences with individuals as units rather than to uniformities within groups and differences among groups. Our inability to discover much has been obscured by our failure to realize the circularity which characterizes explanations which have been made by constructs such as "drives," "survival," and "individual differences."

What, then, do we mean by motivation? Because it commonly points to the goal toward which behavior is directed, what ever else it may include, we may define it as the purposeful organization and direction of behavior. Inasmuch as goals are not implicit in the organism but are acquired through social participation, the word "purposeful" is

intended to put our use of the term motivation entirely on the social level of analysis.

Roles are the motives of men. Considered from the standpoint of groups, roles are the recipes for behavior. They are the symbolic statements of what ought to be paid attention to, what kind of action ought to be taken, with whom, toward what objectives. Considered from the standpoint of the individuals who play them, roles—once adopted—are the very definitions of the persons themselves. John Smith, President of X Corporation, does not define himself as "one who plays the role of president of X Corporation." He *is* President of X Corporation. This may not be all that he is, but the other things which he is are of the same order. The role is antecedent to the individual who adopts it, who by adopting it both defines himself as an object in terms of it and takes over the socially approved plans of action which it comprises as his own. They are then his motives.

In order to define a role, we must specify what attitudes constitute it. Attitudes are the plans of action toward the objects which are significant to the role being played. Their counterparts in the structure of the group are the norms which serve as the social definitions of situations and of roles. The role, then, is the over-all plan of action of which the attitudes are the constituent parts. The role as the role-player himself conceives it is the large design of motive, but one must not conclude that it is simply a sum of the subsumed attitudes, for any one of them makes sense only in terms of the role as a whole.

The term "attitude" is commonly used by social psychologists to mean a persistent tendency to act in some specific way. We accept this definition, provided it be understood that the term refers to events at the symbolic (social) level rather than to events at the physiological level. By attitudes, we mean verbal statements which constitute blueprints for behavior. These statements indicate the ends toward which action is directed, the justifications for holding these ends or values, the proper methods of achieving the ends, and the proper feeling and evaluation regarding degrees of success or failure in achieving the ends.

Motivations differ, of course, not only between groups but within groups. In any given group we do not find a standard motivation for two reasons. Each member belongs to a number of other groups which may have different or even conflicting values; and the group includes a number of different kinds of roles. Yet the group's very existence hinges on the common acceptance of a minimal common core of values for every member; so to establish the fact that an individual identifies himself with a particular group is sufficient to enable prediction of his motivation for a considerable range of behaviors.

The aim of science is to establish the most economical ways of describing the regularities of behavior. It may appear that we have here discarded earlier theories of dependable regularity of motivation (e.g., profit maximization, biological drives) without offering in their place any economical method for establishing regularities in the tremendous variety of motives described by social roles. It is true that the methods needed are only in process of being formulated and tested. Yet enough has been done already to establish the possibility of determining with what reference groups individuals feel identified and of finding relatively high correlations between these identifications and significant attitudes toward a wide variety of situations.

If one accepts this general frame of reference, then the intensive study of the role of the manager is the clearly desirable avenue toward the delineation of his motives. We shall now merely suggest some of the types of information presently available which bear on the role of the manager and on the manager's conception of that role. Any sketch of the social role of the corporate executive must start well beyond the corporation itself. Our first concern would be with the larger socioeconomic-political environment within which the contemporary firm and its leadership must operate. This familiar environment features not only such visible elements as big government, big labor, and other competing power blocs, but also an extensive and influential body of attitudes. These forces and these attitudes furnish many of the limits, constraints, and inducements which condition business motivation and behavior.

The manager must then be examined within the setting of the firm itself—often a corporation in which the stockholders have a rather nominal control and in which an apparently autonomous management appears to largely run the show. The preoccupation of the executive with his corporation as a sort of independent entity, whose welfare is to be maintained and protected, is powerfully reinforced by the fact that he is a member of a group interested in the same things. Modern management—especially in the large corporation—operates in a group setting, with group decisions—and group attitudes, constraints, and aspirations—although individual roles may be sharply differentiated. Members of management play a distinct role in the corporate scheme of things, and within the confines of that general role there are dozens or hundreds of specific roles. Each man attempts to fulfill his role, and if he is blocked in his attempt to play this role, he is frustrated and he often resists, although he may ultimately accommodate.

In his role playing, he is also concerned with his groups "outside" the corporation—in the community, neighborhood, club, and home.

There is, of course, some carry-over of his managerial role. William Henry notes (in *American Journal of Sociology,* January, 1949):

In both its economic and its social aspects the role of the business executive is sociologically a highly visible one. It has clearly definable limits and characteristics known to the general public.

This role comes to have compulsive power as far as the manager is concerned. Chester I. Barnard has observed (as reported by R. Richard Wohl in *Change and the Entrepreneur,* pages 9-10):

Often enough, an individual will be confronted with an offer to take on a particular job. He may think this job distasteful or hazardous. He may not wish to take it on. He is not overtly compelled to do so; he is invited to accept or reject the tender. But he accepts it. For should he refuse to accept it, he would lose caste with his associates, a consideration which rules out the apparent discretion he supposedly enjoys. He takes the task, and works at it, because part of his "job"—his role—is to deal with it. . . .

The role played and the personality of the man playing it are not unconnected. Henry further comments:

It is not a game that the person is playing; it is the way of behaving and thinking that he knows best, that he finds rewarding, and in which he believes. Thus, the role as socially defined has its counterpart in personality structure. To some extent, too, the personality structure is reshaped to be in harmony with the social role

He adds, however, that the necessity for such reshaping is minimized by the initial selection process. Henry has undertaken an intensive analysis of the personalities of a group of over one hundred successful business executives in various types of concerns. He has found eleven personality characteristics shared by this group. He has also concluded:

The successful executive represents a crystallization of many of the attitudes and values generally accepted by middle-class American society The value of accumulation and achievement, of self-directedness and independent thought and their rewards in prestige and status and property, are found in this group. But they also pay the price of holding these values and of profiting from them

This analysis suggests, of course, that research has scarcely begun. It may also give some clue, however, as to lines of research that hold promise and which might now be explored if the orientation proposed herein is to be tested or applied.

It will be necessary to identify the values and norms of the larger American society in which the manager lives and functions, presumably by such empirical means as content analysis and attitude measurement of these values. It would then be possible to compare and contrast these over-all values with those values which have been held by managers alone, probably as the result of their special reference-group identification. An inquiry could then be conducted into the differential types of associations holding these special "motivational vocabularies" which mark the manager off from the other members of his society.

It would be important also to determine how managers define the over-all society and how they see themselves in relation to it. How are

the groups and categories of our society defined as social objects by managers? What channels of communication, mass or otherwise, are used by managers and what definitions and values do these channels purvey? How differently do those who play other recognized roles in society define that society?

Another crucial research tack would have to do with motive blockage. What happens when the group-held values, such as that of profit maximization, are perceived by managers to be blocked by action of government or labor? Under what conditions is there conflict, under what circumstances is communication cut off, and when is there accommodate change in values and role?

A number of studies along historical lines are also needed. Just how has the role of the manager changed during the past several decades? Specifically, what changes have occurred in the manifest and latent functions of the corporation to the larger society, in the system of roles constituting the structure of the corporation, in managerial perceptions of and attitudes toward these changes, in the vocabulary of motives used by corporation managers, and so on?

Finally, it would be important to examine the whole range of groups with which managers feel identified. If, for example, they do feel identified with their communities, social cliques, and families, it would be useful to explore to what extent the norms from these groups converge to a single value-system including that derived from the managerial role itself and to what extent they conflict with each other. If they do conflict, how are they handled? Do they become compartmentalized, in accordance with norms supplied with the managerial role itself, or do they complicate his motives as manager in some regular and describable ways?

A final question remains. Are there effective research techniques available with which this approach can be tested and applied? A theory without research techniques is a mere set of circularities—an attempt to explain by naming. The theory which we have set forth in this paper is well over half a century old, but only within the past decade have research techniques appropriate to it been employed. Fortunately, however, the major difficulty has been in coming to some agreement about the class of phenomena which is to be investigated. Now that there is a growing agreement that the self is a set of attitudes, we are able to bring to bear the techniques of attitude measurement which have been developed over the past quarter to the point where Newcomb can speak of measurement of attitudes as the greatest technical achievement of social psychology. The techniques we are able to employ in the identification and measurement of self-attitudes are thus ones which are already considerably refined and rather rigorous.

Empirical treatment of self-attitudes, nonetheless, is in its infancy. Although the application of attitude-testing techniques is now possible, there remain some complicated problems besetting the researcher into self-attitudes. First, it is very difficult to know what kinds of items to construct for inclusion. Second, there is the very great danger of suggesting responses to the respondent. Third, there is the possibility that the self-attitudes which are elicited will be those which are relevant only to highly limited situations.

A self-attitude test has been constructed which meets all of these difficulties. It consists of asking the respondent to give, as if to himself, twenty different statements in answer to the question, "Who am I?" In asking this pertinent but very inclusive question in this way and by requesting multiple responses from each respondent, the formulation of relevant items is left up to the respondent. Thus the first problem is solved. We may assume that when the respondent formulates the items himself they must be relevant, at least to him. By asking such an inclusive question as "Who am I?" and by asking the respondent to direct it at himself and to answer as if to himself, we minimize the possibilities of suggestion to the vanishing point. Finally, by phrasing the question in this extremely general form we minimize the risk of cueing in the specific situation under which the test is being administered.

This test—termed the "Twenty-Statements Test" by its authors, Manford Kuhn and Thomas McPartland (see *American Sociological Review*, February, 1954)—is what is known as an "open-ended" test, which requires for any kind of systematic treatment of results some kind of content analysis of the replies. The most useful content analysis which has been made of replies to this test is the sorting of statements into those which are "consensual" and those which are "subconsensual." A consenual statement is one which requires no further explanation in order to be understood by the analyst or anyone else. A subconsensual statement is one which refers to norms which vary and which must be inquired into if the statement is to be at all denotative. Significantly, it turns out that the consensual statements, in overwhelming proportion, refer to the respondents' statuses in social categories and groups. It further emerges that respondents, if they have any consensual statements at all to give, give them first.

We earlier made the proposal that it is necessary to know how managers define themselves in order to find out the regularities in their motivations. We have now suggested a probable line of attack. We must ask what we want to know. If this sounds simple-minded, we must remind ourselves that the habit of asking some other, perhaps quite irrelevant, question (e.g., "What do you see in this ink blot?")

is fairly endemic in our society today. We have come as a society quite prematurely to the conclusion that man is irrational, and that there is no use asking people who they are and what they are doing or what is important to them. We have here suggested some direct questions which have demonstrated initial promise and for which there are some fairly rigorous techniques for manipulation already in existence.

We have advanced in this paper the suggestion that self- or reference-group theory may provide a useful approach to managerial motivation, and that it has effective associated research tools. If this claim proves by inductive test to be valid, as we hope that it will, then it will have demonstrated that the regularities of human behavior are such as to support the proposition, not that man is irrational, but that he is rational in a broader, more inclusive sense than previous models have been able to describe.

DISCUSSION

ALBERT LAUTERBACH: By agreement with the chairman, I should like to use most of the time available to report briefly on research which I carried out last summer, with the aid of the Social Science Research Council, on managerial attitudes in Great Britain, Norway, Sweden, and Western Germany. All of these countries are characterized by the coexistence of private, public, and co-operative enterprise, in varying forms and proportions. It was the specific aim of my study to explore the perception by managers of the managerial function as such, managerial incentives and success, division of responsibilities and risk-taking, the qualities desired in executives, the leadership role of managers, and the impact on management of national and cultural differences.

My project was meant to be a pilot study, and no quantifiable results were aimed at. Those interviewed, however, included a cross-section of managers in large private corporations and medium-sized family enterprises in a variety of industries, and managers of publicly and co-operatively owned enterprises; also union officers and shop stewards and research workers and public servants in related fields. The managerial sample included many persons who had had executive experience both in private and in public or co-operative enterprises.

The appointments were based on suitable contacts and introductions, and the interviews were semistructured—the prepared questionnaire was used in an informal and flexible way. The total number of interviews was 134, including 75 managers, 19 union officers and shop stewards, and 40 public servants and researchers. The results obtained should be interpreted as raw material in formulating pertinent questions, in throwing some light on the multitude of variables involved, and in posing some promising hypotheses for future testing. With this qualification, the results can be summarized as follows:

1. The ownership situation carries far less weight in determining the basic attitudes of managers in most kinds of enterprises, especially the large ones, than has traditionally been assumed by supporters of capitalism and socialism alike. Ownership, of course, remains of considerable importance in its legal and financial aspects, but for managerial attitudes other variables—such as size and organization—appear to be of equal or greater impact. This was emphasized by many of the managers themselves as well as members of other groups, including labor. I was especially impressed by the remarkable success of certain enterprises in Germany which have long been ownerless; they have been managed effectively by able men without anyone really knowing for years to whom these enterprises were going to belong eventually—to private owners, to the employees, to the state, or to foreign interests. The personnel director of one of these enterprises—a very large one—commented as follows: "We have assumed a certain basic capital for the balance-sheet, in a fictitious way; but there really are no stocks. Legally, it is an absurd situation. But we want to perform as if the plant belonged to us, that is, to both management and the employees."

2. The personal qualities of a manager are widely considered the most important element both in his attitudes and in his performance. Technical competence is taken for granted as a requirement in specific jobs, but for top management it is often rated less important than organizational gifts, vision, and a strong personality in general. For the rest, the personal qualities required in managers are frequently summarized as "character," meaning as a rule the ability to get on with people, to participate in teamwork, and to supply leadership without authoritarian traits. The significance of personality variations in managers was stressed especially by labor representatives in Sweden and Germany. Persons with the managerial qualities mentioned are widely judged as capable of performing well in any ownership form of comparable enterprises—private, public, or co-operative. Actually I found interchange of managers between these ownership forms to be fairly frequent, especially in Britain and Sweden.

3. Nonbureaucratic and competitive forms of management organization are almost universally regarded as essential if the best personal qualities of managers are to work out in practice, regardless of how the enterprise is owned. In particular, a sharp distinction is often made between those state enterprises which are subject to political controls and those which are organized as independent corporate units. Comparable yardsticks are applied to the organization of large private corporations. In Norway, where both bureaucratic and nonbureaucratic forms of state enterprise are represented, the sharp distinction mentioned is usually drawn by private managers as well as other people. For that matter, the head of an autonomous state plant in Norway pointed out that it was just as essential for him as for his private competitors "to have *time* to use commonsense"; that is, to enjoy both independence and relative freedom from routine duties.

4. Private management attitudes toward the government, not unexpectedly, are generally characterized by a desire to keep intervention down—a desire which is often shared by managers of co-operative enterprises and sometimes by officers of labor unions, too, even where their influence upon the government is strong. (The *functional* differences involved were stressed frequently by spokesmen for the Swedish co-operatives, labor, and government, which all favor the same ideological creed.)

The strong emotional, if not fanatic, undertone, however, which is so frequent in American business attitudes on the question of public intervention, is usually missing in the European countries studied. Certain areas of government intervention, even state ownership, are widely regarded as legitimate by private managers. The whole issue of government and business is discussed in Britain and Scandinavia on pragmatic grounds in each case, not as a matter of dogma or a quasi-moral issue of absolute character. The chairman of a large British concern told me that as a Conservative he would have put the nationalization of coal into his program, though it might have been suspect coming from a Conservative. He also approved of the nationalization of electricity and gas, as a device against a "parochial outlook," and he would add water supply. On the other hand, he was emphatically opposed to nationalization or public supervision in his own industry and

most others: "If we were open to investigation of all the silly things we do, we'd never get anywhere. We need authority to make mistakes."

Conversely, a socialist leader in Norway emphasized that his party no longer advocates nationalization or even intervention for its own sake, that they judge each case on its merits, that intervention should be confined to fields where private business fails or is inapplicable (because of war effects or large capital needs, for example), and that even there the trend leads away from centralized planning ("try to regulate the climate; don't try to count the raindrops"). Such attitudes are now fairly frequent in both ideological camps.

5. Delegation and decentralization of responsibilities is widely considered conducive to initiative and risk-taking on the part of individual executives; but top managers tend to emphasize that final decisions are unmistakably reserved for their own uncontestable authority. This again applies to all ownership types of enterprise, with some variations in emphasis or hopefulness. I heard a leading German banker give the following reason in explaining why he had quit the presidency of an important public enterprise: "I like to be with an institution where I can refuse a credit application without having to give a reason." Many public and co-operative managers in each country were no less emphatic in stressing the importance of individual responsibility, decentralization, and delegation of managerial authority. For example, managers of the public electricity and gas boards in Britain were practically unanimous in praising the decentralization in their industries compared with the older, centralized pattern in the nationalized coal industry, while executives of the latter were somewhat defensive on this point.

6. The managerial function as such is, of course, in part associated with the achievement of a profit or surplus for the enterprise; but it is widely perceived as exceeding this goal in many respects, even when the goal is qualified by long-range considerations. Additional elements of the managerial function are seen in striving for a firm financial basis and public standing, assurance of stable employment, up-to-date equipment and possible expansion in the interest of coming generations of managers and owners, and the performance of a public service of one kind or another. Rationalizations undoubtedly occur but the frequency of a broad conception of the managerial function, again with rather limited variation according to ownership, is certainly interesting. A somewhat extreme case was presented by the head of a medium-sized family enterprise in Norway, who is a supporter of Moral Rearmament and sees the real function of management in "helping to make people happy," by creating mutual confidence among all the groups in industry. Thus far, it is true, he has done little about it on the practical level.

The chairman of a large and profitable company in Britain commented as follows: "You have to give people a field in which they feel they can perform; satisfaction comes from *performance*, from fulfilling oneself (assuming the income is adequate). Remuneration *is* weighed in industry—as something to get out of your way as a problem, in order to do the things you are really interested in."

7. Managerial job satisfaction, accordingly, is related only in part to financial achievement in the sense of either profit or individual income. Or,

rather, profit is widely considered the indispensable starting point of managerial job satisfaction, not its true essence. The latter is mostly seen in doing the job itself; that is, in being active, getting things done, fulfilling an assignment, justifying the trust of associates and employees, building an up-to-date and durable structure, being considered successful by others, being respected, doing something useful, meeting a challenge.

The divisional manager in a British nationalized industry introduced himself with the words, "I am a capitalist," and wound up the lengthy interview with the words, "I am a violent antisocialist." But in between, he explained elaborately why he had quit his prosperous business in the same industry, why he had accepted the government job (after first heading a committee against nationalization), and why he opposed current schemes of denationalization as impairing efficiency (interestingly, he slipped once in referring to his government board as "my company"). His reason for accepting and carrying out the assignment, despite hostility to nationalization in general, was that he welcomed the opportunity to prove that he could handle a very big job. He was now proud of his financial and organizational achievement and enjoyed thoroughly the importance of his job. Moreover, he loved this particular industry which, he said, was "in his blood," and was going to remain loyal to the job still to be done in it, regardless of ownership.

Another element of managerial satisfaction was exemplified by the head of a medium-sized family enterprise in the British Midlands, who emphasized that aside from the balance sheet, the reputation of the company in the town mattered very much: "We all belong here. We were brought up that way."

8. Human relations of a desirable type rank high in the scale of managerial satisfactions. Distinct traces of paternalist attitudes can still be found, especially in older managers and in family-type enterprises. In fact, the family background or history of certain enterprises—including some very large ones—is often considered an asset. At the same time, the importance of good communication of the give-and-take type is now widely recognized. Various types of joint consultative committees are being tested in all of the countries mentioned. On the other hand, direct participation of employee representatives in managerial decision making has thus far been attempted only in the German steel and coal industries and is quite controversial there at this point.

The director of a German employers' association felt that "every employer has the shop council he deserves" and that there is something to be said for "the workers sharing the employer's worries." However, he also felt that the codetermination scheme went much too far in encroaching on property rights, in bringing alien elements into each enterprise, and in confusing the accustomed dividing lines between unions and management. This last point was virtually confirmed by some labor representatives, too. However, the *Arbeitsdirektor*—one of those strange new hybrids who are approved by the unions but are part of top management—in a large private enterprise pointed to the loosening up of industrial relations under this

act: "People remain in permanent conversation now; those old terms exploiter and agitator are no longer used; the employees now feel that they are no longer at the mercy of an inscrutable management." In the three other countries, however, I found very little interest on the part of either labor or management in any comparable scheme for codetermination, though joint consultation was endorsed, in varying forms and degrees of enthusiasm, by the majority of those interviewed.

9. Varying national and cultural traits appear to be of considerable significance in explaining managerial attitudes in each country, especially the attitudes toward employees and their organizations. Where the population has come to believe generally in persuasion and co-operation—often after a stormy industrial history—management interprets its social role and executive leadership function with restraint, and labor reacts accordingly. Despite outward similarity of the technical forms of industrial management, therefore, the actual attitudes and behavior patterns of both management and labor vary considerably according to the general value system of the population concerned.

A few of the executives interviewed, it is true, saw little difference between managerial problems of the various countries, but most of those who had had first-hand experience abroad took a different view. The head of a Swedish bank felt that most Swedish businessmen would be considered radical socialists in the United States. A Norwegian industrialist who is familiar with Germany contrasted the German readiness to be disciplined with the Norwegian desire to be told "why" and to be held in esteem. The chairman of a large British concern with international links thought the national differences in the way in which one gets co-operation to be most significant even when the forms of industrial organization are similar. He claimed that in the experience of his company in France, for instance, "no rules were possible," but that significant differences also existed within Britain; for example, between the courteous ways of both managers and employees in the Midlands and the intensely emotional reactions of their colleagues in Wales.

Systematic testing of the tentative results and hypotheses that were just presented and illustrated, with possible quantification of the additional data to be secured, would seem to be very promising. Such a study would require the prolonged co-operation of research institutes in every country to be included. More areas with diversified types of enterprise ownership should be added to the sample. In such co-operation, American participation could provide methodological leadership as well as a co-ordinating influence. The international exploration and comparison of the various determinants of managerial attitudes could put greater realism into the continuing debate on the merits and trends of economic institutions.

W. W. Cooper: The requirement of reviewing two papers within the limited time allotted to a discussant makes it desirable to confine attention to a few selected points from the many covered in these papers. So far as

possible, both papers will be discussed simultaneously and my own comments introduced as seems appropriate. I shall then conclude with some general observations and suggestions.

At the outset it may be well to qualify my remarks by noting that both papers apparently represent only parts of larger pieces of work to which I have not had access. It may be helpful, also, if I note that a fair assessment of these papers requires a rather broad view of economics as the science which is concerned with describing, predicting, assessing, and prescribing methods for changing economic institutions; i.e., institutions which are viewed as being primarily devoted to organizing and allocating scarce resources. Furthermore, these institutions need to be considered in both their formal and informal aspects.

Both papers are concerned with new directions for research in economics and both draw from "alien" disciplines. Drawing on the literature of business and administration Mrs. Penrose seeks to incorporate into economic theory the processes of entrepreneurial (or quasi-entrepreneurial) recruitment that firms have available. By this means she seeks to explain the growth of firms (over time) as well as limits to their size at any point of time. Mr. Hickman proposes to study managerial motivation by drawing on the constructs of sociology, psychology, applied anthropology, and related fields. In particular, he seeks to provide an empirical basis for establishing the range and relative importance of various managerial motivations, including profit maximization.

This general statement of their objectives already provides an example of important differences in the approaches of the two authors. Mr. Hickman's approach is empirical; Mrs. Penrose's is theoretical. This remark requires elaboration in order to avoid possible misinterpretations. Mrs. Penrose, in the traditional manner of economists, poses her problem in the context of certain large "facts" which appear to demand explanation: The fact in question is that firms at any particular point in time are clearly limited in their size and yet these firms by various devices which are evolved by themselves or others—e.g., training of a larger managerial class and development of new devices for recruitment, co-ordination, etc.—are enabled to grow beyond these limits at subsequent times. Her formulation can, at least conceptually, lead to empirical validation and reformulation The important point is that her approach, even though resting in part on alien disciplines, seeks to provide a basis for systematic synthesis and change of the existing body of economic doctrine or theory.

Mr. Hickman does not take his facts for granted -other than some obviously inadequate and perhaps unguarded methodological statements culled from certain economic texts. He proposes to begin by collecting the necessary facts. Moreover, his approach rests squarely on the methods and knowledge of the disciplines he proposes to use. His paper does not make clear how either these methods or knowledge, or indeed his own findings, will be systematically used to synchronize with or to alter the existing discipline of economics. It is possible, of course, that this question is premature (or that it has been answered elsewhere), or that Mr. Hickman will be content with the cumulation of a body of factual information which he feels is

important in its own right. The task of assessment would have been facilitated if he had clarified the status of this matter.

Both papers promise an access to new problem material which is welcome in an area of economics which has not provided an adequate bridge for this purpose. An adequate bridge would, I believe, provide for two-way traffic. It would not only enable economists to move across it in search of the facts that their theory (or motivation) seems to require, but would also enable the world of economic institutions to bring to economics the kinds of problems which ought to be occupying our attention in the quest for new knowledge (and new light on old knowledge). The kinds of interrelations and communications that have now been achieved between governments and economics at the macro level might prove equally fruitful in the area that deals with the business firm at the micro level.

Of the two papers presented here, Mrs. Penrose's seems to offer the most promise in this direction. This may seem strange in view of the fact that her paper appears to be much more closely aligned with traditional economic formulations. Indeed her propositions can be regarded as rather simple extensions of the observations of Kaldor, Chamberlin, and others on the status of the entrepreneur as a fixed factor guaranteeing the ultimate appearance of diminishing returns to limit the size of firms. There is a difference, however, which may emerge more strongly in subsequent work. To explain the existence of these limits and, simultaneously, to explain growth beyond these limits, Mrs. Penrose has adopted the expedient of splitting the entrepreneur into a variety of planning agents. By this means she is able to fix the amount of entrepreneurship that the firm has available at any point in time and allow it to grow over time. This represents a step away from the traditional viewpoint wherein the business firm is treated as an elementary economic unit composed of an entrepreneur and selected factors of production This simple entrepreneur-factor model of the firm as an organization is adopted for economic analysis, not, it may be argued. because economists are unaware that it is oversimplified for individual firm analysis, but because it is adequate for purposes of industry and general social analysis. I believe that this argument is subject to serious qualification in many respects. It leaves many questions unasked and unanswered. It also seriously hampers our ability to test many fundamental economic presuppositions.

In any event, Mrs. Penrose has taken, I believe, a step toward repairing the deficiency. Efforts to push further in this direction will, I think, lead inevitably toward analysis of the structure of business firms as a means of explaining their behavior. The difference in approach that I am attempting to portray may, perhaps, most easily be understood by reference to regarding the atom and the cell as the elementary units for analysis of matter and living organisms in contrast to regarding them as units with a structure and organization which require representation both in their own right and as part of the general study of physics and biology. By further movement in this direction we may secure a more adequate model of business firms which will assist in building the kind of bridge previously referred to. This may add to the layer of "aggregation problems" that economics now confronts but

it need not divert it from the task of social analysis—any more than modern physics has been diverted from the task of explaining physical behavior or any more than biology has been diverted from the task of explaining the behavior of organisms. In many cases our units, the firms, are so gigantic (or occupy such positions) that an adequate explanation of their behavior will suffice for an explanation of industry behavior as well. In other cases the devices of "representativeness" can be employed to advantage. Techniques of stratification and clustering can also be used if required.

It seems to me that Mr. Hickman is moving in a different direction. Unless he is willing to make rather strong assumptions which would equate managerial motivation and business firm behavior, his proposed agenda of discovery, even if successful, will not necessarily provide us with adequate descriptions, predictions, or assessments of these economic institutions. Failing these assumptions (and their validation), his analysis can provide us only with a means for gaining insight into the opinions, utterances, and behavior of a managerial "class." This is not to say that his analysis will be irrelevant to business firm behavior even in this extreme. Such class behavior might by a circuitous route—e.g., through its effects on government, public opinion, or the behavior and opinion of subordinates, union officials, etc.—affect the behavior of business firms. The point I am seeking to make is not that Mr. Hickman's findings will be valueless but that underlying his seemingly radical proposals is a model of the business firm which is of the same kind as the traditional economic version—an organization in which entrepreneurs, managers, or some dominant group of managers manifest their wishes and the firm behaves accordingly. For example, the entrepreneur "selects" an optimum transformation or cost function because he wishes to maximize profits. A study of the literature of standard costing or cost accounting practice will reveal that this is not the case. (See, e.g., James L. Dohr and Howell A. Ingraham, *Cost Accounting Principles and Practices* [New York: Ronald Press, 1946], Chapter 28.) Optimum costs, even when known, are regarded as undesirable bases for guiding and controlling behavior. Organizational (and psychological) considerations arising from the systems of delegation and control employed by modern business enterprise enter into these optimality rules in a way which is not comprehended by the traditional economic model of the firm. I might add that these considerations also enter into the methods of cost record keeping and estimation in a way which may make the resulting costs unsuitable from the standpoint of traditional economic analysis, even though essential to survival and maintenance of the firm as an organization.

Both papers invite far more attention than can be devoted to them here. Both are incomplete, imprecise, unclear, and unbalanced. But this criticism needs to be interpreted in the perspective of what the papers being reviewed are attempting to achieve. It is unfair, and perhaps dangerous, to demand such perfection and clarity from papers which constitute pioneering efforts in new directions as might be demanded from papers which restrict themselves to areas which have already been explored and partially settled.

Although she utilizes much of the traditional apparatus of economics in the form of indivisibilities, idle capacity (overhead) costs, etc., Mrs. Penrose's

model can also be represented by the differential equations of biological growth. (*Vide* V. A. Kostitzin, *Mathematical Biology* [London: Harrap and Co., Ltd.].) By splitting the enterpreneur into groups of planning agents, however, she has begun to introduce something which is to be found neither in traditional biological growth models nor in traditional economics. A further step consists of introducing hierarchical arrays of such agents as the common method for effecting recruitment and securing integration and control. She can avoid some of the difficult and tortured translation of traditional definitions and categories of cost to be found in her paper, I believe, by recognizing explicitly that she has departed from the model which gave them their original meaning. This is implicit, for example, in her description of planning "agents" as unused "factors"—as unused or wasted resources from the standpoint of operations, even though perhaps fully utilized from the standpoint of planning for future activities. J. M. Clark's concept of idle capacity and overhead cost does not sit any more gracefully and easily in this context than does E. A. G. Robinson's concept of "unbalanced additions." Nor is the problem resolved by reference to long- and short-run costs and profit maximization.

The distinction between planning and operations drawn by Mrs. Penrose is a real and significant one. I believe that she can more fruitfully proceed by maintaining this distinction than by assuming that planning agents become operating agents when their plans are put into effect. Preserving these distinctions will require introducing what Professor H. A. Simon (*Administrative Behavior* [Macmillan, 1948], page 9) calls "vertical" specialization into the model of the firm as well as the "horizontal" specialization which is envisioned in the usual process of labeling variables in the production function. A really good planning agent is likely to remain in the planning hierarchy (in a so-called "staff" capacity) rather than become an operating agent (in the so-called "line" organization) even when his plans are adopted. For concreteness, one might think of an operating agent in terms of the usual production foreman and a planning agent in terms of the usual industrial engineer (standard setter) or budget officer.

By introducing a hierarchical array of planning agents Mrs. Penrose will have introduced a new array of problems (e.g., the phenomenon of agent promotion within the hierarchy) into economics. As she correctly notes, this will also help throw new light on old problems as well; e.g., the problem of handling uncertainty at various levels of entrepreneurship or quasi-entrepreneurship within the firm over time. (It is for this reason that I have persistently referred to these persons as agents to designate a category lying between the traditional entrepreneur and factors of production.) The addition of another hierarchy of operating agents will add still further elements of richness. In particular, it will expose the problems of co-ordination and control that are most easily thought of in terms of still a third hierarchy of agents—a group that may be thought of as control agents (e.g., accountants). The systems of internal control maintained by such personnel are designed and maintained for this purpose within the context of the delegations made within and between the other two hierarchies.

A moment's reflection on these arrays will reveal, I believe, why the ac-

counting system must be maintained in terms of the documented historical cost record of the accountant rather than the undocumented opportunity costs of traditional economics. Control may be visualized as the process of securing conformance between plans and actions—a process, it should be noted, which may require adjusting plans to actions as well as the reverse. (See E. L. Kohler, *A Dictionary for Accountants* [Prentice-Hall, 1952], page 108.) Clearly it is as undesirable to allow industrial engineers (planning agents) to set arbitrary standards of performance as it is to allow production superintendents (operating agents) to behave arbitrarily with respect to these standards. This is the nub of the problem of internal control and system design as visualized in accounting, especially if one views it in the context of a system of authority delegations which makes it desirable to minimize upper level intervention in operations and plans. Efficiency can then be viewed in terms of the levels at which the controls operate (e.g., costs and volumes) as against possible alternatives. Opportunity cost thus may become an ancillary device for the accountant although a primary device for operating and planning agents.

Models constructed along these lines will, I believe, provide more adequate bases for understanding, predicting, and assessing the behavior of individual business firms engaged in allocating scarce resources. They will, of themselves, suggest new problems and methods of attack. Perhaps even more important, such models and studies should contribute toward building a more adequate bridge between economics and business firms.

I am afraid that I have few suggestions to make in connection with Mr Hickman's paper. A good deal depends on whether one agrees with his optimistic assessment of the state of the knowledge and the methods of the sciences on which he proposes to draw. I do not feel wholly qualified to render a judgment on this although, in common with many other economists, I have myself been disappointed in past attempts to draw on these disciplines I remain to be persuaded, however, that we will be able to use these techniques without a good deal of selection and adaptation, although I should hasten to add that I feel the same way about techniques drawn from other fields as well. (That this is true even in such purely methodological fields as statistics has been made clear by recent work of the Cowles Commission and others in relation to problems of structural estimation and identification.) For example, what I am told are Professor Linton's applied anthropological constructs of status and role may be suitable approximations for analyzing an informally organized society. It is by no means clear that they will prove equally useful in discussing entities, such as business firms, which have important elements for formal organization as well. Lazarsfeld, Newcomb, and others may have reported some success in applying these constructs to studies of the American soldier in a military organization which does have important formal aspects. But it should be realized that the relative permanence of status designations in such a military organization may be misleading in studying (competing) business organizations. Perhaps a more apt analogy is in terms of a play being put together and operated by a director who retains the right to edit the script and change both status and roles in the light of his judgment of

the actor potentials at his disposal and possible competing plays which are (or will be) produced at the same time.

I have already indicated my uncertainty as to how Mr. Hickman proposes to translate his findings (and methods) into the institutional entities with which managers, qua managers, are concerned. Perhaps by beginning with already available data, such as the Commerce Department-SEC series on plant expenditures, he could effect such a translation. The types of methods he employs in terms of self-theory (self-directed depth interviews, content analysis, etc.) are likely to prove quite expensive even if he restricts his attention to such ongoing series. If he proposes, instead, to employ himself in studying motivations, aspirations, etc., of a managerial class, the task is likely to take on truly forbidding proportions. Even modern sampling methods would require huge numbers to achieve any degree of representativeness from some five million firms of varying sizes scattered over a multiplicity of industries and regions—and status, self, and role are likely to vary to some extent with each of these properties. Of course, he may restrict his studies to a handful of firms and managers. He would then face, it seems to me, a rather difficult problem of generalizing his findings concerning the relative importance of different kinds of motivation in a form which would command the confidence and respect of others. Such empirically oriented studies as he proposes would require this kind of confidence and respect if they are to have the effects he indicates.

I am afraid that I can do little more than point out these possible pitfalls to Mr. Hickman. One way to circumvent some of them would involve the construction of adequate models utilizing, at least tentatively, the kinds of findings that Mr. Hickman might conceivably envision as an end product of his studies. Such a course would involve some degree of change in emphasis and timing in Mr. Hickman's proposed agenda. In any event I have already devoted sufficient attention to suitable models of the business firm in my comments on the paper by Mrs. Penrose

PRICE AND WAGE FLEXIBILITY

ECONOMIC CONCENTRATION AND DEPRESSION PRICE RIGIDITY

By JOHN M. BLAIR
Federal Trade Commission

On January 17, 1935, the Seventy-fourth Congress of the United States issued Senate Document No. 13, *Industrial Prices and Their Relative Inflexibility*, thereby touching off what became one of the most vigorous controversies in recent economic literature. On one side of the issue was Gardiner C. Means, who, as Economic Adviser to the Secretary of Agriculture, had prepared the document which was then, in his words, "commandeered" by the Senate. With him were Ralph C. Wood and, at the time, J. Kenneth Galbraith. On the other side was a more numerous host, including Willard Thorp, Rufus Tucker, Jules Backman, Edward S. Mason, Don D. Humphrey, Alfred Neal, Ernest Doblin, and others. Following the publication of the Senate Document, the controversy progressed from general arguments in the economic journals to elaborate statistical works, the most ambitious of which were prepared by Means, Thorp, and Neal. The outbreak of World War II had the effect of severing the strands of argument, and since that time the whole controversy has remained more or less in a state of limbo.

The controversy ranged over a number of economic issues, only one of which—the relationship between economic concentration and price flexibility—will be discussed in this paper. Among the issues which will not be examined are the economic effects of price rigidity, the relationship between price and production behavior, the history of price rigidity, the various statistical measures of price change, the adequacy of the data used to measure price behavior, etc. Obviously, each of these topics could, in itself, provide the subject for one or more papers. And even on the one topic to which this paper is limited, time does not permit a discussion of the general and theoretical arguments offered in the controversy.

The principal evidence was offered by Gardiner C. Means on the one side and by Willard Thorp and Alfred C. Neal on the other.[1] Putting

[1] National Resources Committee, *The Structure of the American Economy*, prepared under the direction of Gardiner C. Means, Pt I, 1939, p 142; Temporary National Economic Committee, Monograph No 27, *The Structure of Industry*, by Willard Thorp and Walter Crowder, 1941, p 357; Alfred C. Neal, *Industrial Concentration and Price Inflexibility* (American Council on Public Affairs, 1942), pp. 91, 92, and 118

it briefly, Means found that an inverse relationship between the level of concentration and the amplitude of price change did exist. Thorp found that it did not. In Thorp's view, differences in behavior were associated not with differences in concentration but with differences in the characteristics of the product. Neal found that "price change is closely associated with direct cost change and is not due to concentration."

Means's analysis has been criticized on the grounds that the price data which he employed, the BLS wholesale price series, do not reflect hidden or secret discounts. Thorp's study is subject to criticism on two grounds: that he employed no standards, as did Means, to eliminate products which are not meaningful for this type of analysis, and that the price data which he used—the census realized prices—may fluctuate merely because of a change in the relative importance, or "weights," of the various individual products within a census product class. Neal's study, which is also based on census data, is open to the same objection, plus the additional criticism that his analysis assumes that during a downswing an industry's direct costs remain proportional to the average weighted price of its products. According to Neal, it is reasonable to assume that during the Great Depression a shift from high-priced to low-priced goods within an industry "would be reflected in the average direct cost index also"—and reflected in the same degree and extent!

What is offered here is a new approach which will bypass some of the more important limitations inherent in the previous studies. Each of these previous studies involves comparisons of different products with varying degrees of concentration. But, as was pointed out during the course of the controversy, products may differ from each other, not only with respect to concentration, but they may also vary with respect to such other factors as elasticity of demand, cost behavior, and adequacy of price data, each of which has been cited as an explanation for the appearance of price rigidity. If instead of comparing different products the same product is examined during two depressions, the effect of these other variables can largely be isolated, since it need then only be assumed that, as between the two depressions, they were affected by no significant change.

Although the Great Depression of 1929-33 obviously suggests itself as the later period to be used in such a comparison, there remains the problem of finding a depression which antedates—though not too greatly—the emergence of high levels of concentration. This problem is aggravated by the fact that in many American industries concentration has been high since around the turn of the century. It happens, though, that immediately prior to the great consolidation movement of 1897-1903 this country experienced a rather severe depression, begin-

ning in 1890 and lasting for several years.[2] In this study 1897 has been selected as the terminal year, since, like 1933, it appears to be a year in which the deflationary forces finally exhausted themselves. Although the depression of 1890-97 was a serious one, no depression in American history has approached in severity the depression of 1929-33. Thus, all other things being equal, a showing of equal flexibility is not to be anticipated since prices would be expected to decline less in the earlier than in the later depression; a showing of greater flexibility in the earlier period would be all the more remarkable.

The price data used in this analysis are the wholesale price series of the Bureau of Labor Statistics. In most cases the description of the product is virtually the same in both periods, although this is not an essential requirement. Price series covering both depressions are available from the Bureau of Labor Statistics for 168 commodities, of which 122 are used in this analysis.[3]

The first step in the analysis is to show the price changes for products which, by and large, were atomistic areas in both depressions. If Means's argument is correct, such products would be expected to show no significant change in price behavior; they certainly would not be expected to show any decrease in their flexibility. Chart I shows

[2] According to the long-term index of "American Business Activity," prepared by the Cleveland Trust Co., the general period was one of depressed economic conditions, with a downswing in 1893 and 1894 ("Panic of 1893"), followed by a very brief upturn ("Recovery of 1895"), which was in turn followed by another downswing of about equal severity in 1896 and 1897 ("Silver Campaign Depression"). Warren and Pearson's long-term index of physical production shows a decided dip ending in 1895, followed by a lesser downturn in the next two years. To the extent that price trends can be assumed to mirror the general state of economic conditions, the available information would suggest that the low point was not reached until 1896 or 1897. The all-commodity wholesale price index of the Bureau of Labor Statistics (with 1913 at the base of 100) declined from a level of 80.5 in 1890 to 66.7 in 1896, rising by only a tenth of a percentage point, to 66.8, in 1897. The majority of the individual commodity groups did not reach their low point until 1897. In describing the period, the Commissioner of Corporations used such terms as "depressed conditions," "commercial depression," "slack demand," "acute depression," etc. (*Report of the Commissioner of Corporations on the Steel Industry*, Pt. I, 1911, pp. 63, 72, 75.)

[3] The products for which price series are available but which are not included in this analysis fall into the following groups: fabricated metal products (17 items); chemicals (12 items); stone, clay, and glass, other than plate and window glass (8 items); petroleum and coal other than anthracite (5 items); nonferrous metals other than copper, lead and zinc (3 items) and miscellaneous products (1 item). The 17 fabricated metal products consist of simple hand tools and fixtures (e.g., saws, axes, chisels, doorknobs, etc.) which are relatively unimportant items and for which information on concentration in the earlier depression is lacking. The chemical and drug items were omitted because of the conspicuous unreliability of the BLS price series for this particular group. The stone, clay, and glass products were omitted because information on long-term changes in concentration is unavailable; this is particularly true of products sold on a regional or local basis within which significant changes in concentration may have taken place. Price series during both depressions were available for only two petroleum products, Pennsylvania crude oil—which is hardly representative of crude oil production—and kerosene—which by 1933 had nearly passed into economic oblivion. In addition to copper, lead, and zinc, price series were available for only three other nonferrous metals—quicksilver, tin, and silver—the prices of which are largely determined by developments abroad or by monetary policy.

CHART I

the price changes in 1890-97 and 1929-33 for farm products in the upper grid and foods in the lower. Each grid is bisected by a line of equal change. Products falling below and to the right of the line had greater price declines in the later than in the earlier depression, with the reverse being true of products falling above and to the left of the line. As will be noted, most of the farm products fall below and to the right of the line; i.e., they showed greater flexibility in the 1929-33 depression than in the earlier period, as would be expected in view of the greater severity of the later depression. This was true of all but 4 of the 19 farm products for which price data are available. The exceptions are potatoes (18), oats (11), barley (1) and hops (10). The change in flexibility of the latter two is largely explained by the unusual circumstance of the repeal of Prohibition; thus the price of hops, which declined by 56 per cent during 1890-97, rose by 174 per cent during 1929-33.

Food products present much the same pattern. Of the 38 items for which price series are available, all but 9 showed greater flexibility in the later depression. The exceptions are three types of dried fruit—dried apples (17), prunes (19), and raisins (20); one type of canned fish—canned salmon (16); and five other processed products—salt (38), soda crackers (26), molasses (28), granulated sugar (29) and coffee (30). Some of these exceptions are worthy of comment.

In the salmon industry, only two of the half a dozen leaders were in existence at the time of the 1890-97 depression. Pacific American Fisheries, Inc., the largest fisher and canner of salmon in the world, did not come into existence until 1902 when, under the name of Pacific Packing and Navigation Company, it was organized "as a consolidation of some sixteen concerns located on Puget Sound and the coast of Alaska engaged in the business of catching and canning salmon." (*Moody's Manual* [1904], page 1516.) Three of the other principal enterprises were not formed until the twenties. By the time of the later depression, the industry was fairly well centralized, with eight companies in 1934 producing more than half and two companies more than a quarter of the output. Moreover, there appear to be both price leadership and a high degree of price uniformity in the industry.[4]

[4] "Although no cooperation or agreement has been proved to exist among the canners, there has been great uniformity in the opening prices [at which about 90 per cent of the pack is sold] since 1905; nearly all canners follow the prices of one or two large companies, and refuse to quote prices until those of the large firms have been announced The Alaska Packers Association has taken the lead in declaring the prices of all grades except one and its prices have been followed by nearly all the other canners in declaring their prices. . . Both the uniformity of the prices declared and the uniformity of time of declaration suggest that the prices of one or two leading firms are used as a guide." (Arthur R Burns, *The Decline of Competition* [McGraw-Hill, 1936], p 139)

The same general type of situation applies to the salt industry. In that field the two leading companies—International Salt Company and the Morton Salt Company—were not formed until after 1897. The former, which now produces about 25 per cent of the industry's output (*Standard & Poor's Corporation Records*, December 8, 1949, page C-2-5), was organized in 1901, acquiring in the next four years the capital stock of eleven independent firms. Similarly, the latter was not formed until 1922, when it was organized as a successor to a line of companies originating in Chicago during the mid-nineteenth century.

In the soda cracker industry, neither the National Biscuit Company nor the Loose-Wiles Company were in existence at the time of the earlier depression, the former having been organized in 1898 and the latter in 1912. According to *Moody's Manual* of 1901: "National Biscuit Co. was incorporated under the laws of New Jersey, Feb. 3, 1898, for the purpose of carrying out a plan to purchase the principal cracker manufactories in the United States. . . . The company owns many baking plants and controls the greater part of the trade in this line east of the Rocky Mountains." (Page 985.) In 1901, it owned fifteen plants. By 1935, National Biscuit and Loose-Wiles, together with United Biscuit Company, sold 74 per cent of the biscuits and crackers produced by the more than 330 American baking establishments, with National Biscuit Company accounting for approximately 42 per cent. (Federal Trade Commission, *Agricultural Income Inquiry*, Part 3, 1938, page 41.) According to the Federal Trade Commission: "In the cracker industry it is stated that manufacturers must and do follow the lead set by the National Biscuit Co. and Loose-Wiles." (*Report on Open Price Trade Associations*, 1929, page 78.) Likewise, the two principal producers of molasses—the American Molasses Company and Pennick & Ford, Ltd.—were not organized until after 1897. The American Molasses Company was incorporated in 1905 as a consolidation of two formerly independent firms: N. W. Taussig Company and Eastern Refining Company. Pennick & Ford, as originally constructed, was not organized until 1898. It was not until 1920 that it was consolidated with the Douglas Company, another important producer, which had been organized in 1903.

Chart II shows the price behavior in both depressions for two other atomistic areas: textiles and lumber. In both, the scatters resemble those of farm products and foods. Two-thirds of the thirty textile products showed greater flexibility in the later depression. Half of the exceptions consisted of one type of commodity: wool products. Similarly, in all but two of the thirteen lumber and wool products price flexibility was greater in the 1929-33 period; the exceptions are bed-

room chairs (12) and matches (13), the latter of which is worthy of note.

While the Diamond Match Company was formed ten years before the beginning of the 1890-97 depression, it was not until 1901 that it entered into an agreement with the British firm, Bryant & May, Ltd., under which the latter agreed "to refrain from manufacturing or selling matches in North America." And it was not until 1903 that it entered into a similar agreement with the Swedish Match Company, under which the latter "agreed not to manufacture matches in the United States except by arrangement with Diamond Match Co."[5] Inasmuch as the safety match had been a foreign development and sales by foreign companies had been an important factor in the domestic market, it was not until these cartel agreements were made that the domestic market could be said to have been controlled. But during the 1929-33 depression, the Diamond Match Company exercised unquestioned control over the domestic market, not only through its position as the leading producer, but also through its holdings in other match companies. In 1939 the stockholders of the Diamond Match Company owned the shares of the Ohio, Lion, Universal, Federal, and West Virginia match companies. Diamond's president held 51 per cent and Diamond itself held the other 49 per cent of the stock of the Berst-Forster-Dixfield Company. These seven concerns, together, produced nine-tenths of the nation's output of matches. (Clair Wilcox, *Competition and Monopoly in American Industry* [TNEC Monograph 21, 1941], page 191.)

Apart from these exceptions, however, the general pattern in each of these four atomistic areas—farm products, foods, textiles and lumber—is the same. As would be expected from the unmatched severity of the Great Depression, prices tended to drop more in 1929-33 than in 1890-97. Against this background, the distribution of price changes in the steel industry becomes of special interest. Chart III shows the price changes in both depressions for nine iron and steel products.

As will be noted, the pattern is the reverse of that of the atomistic areas. With one exception, hot-rolled sheets (7), the observations fall above and to the left of the line of equal change; i.e., prices dropped less in the later than in the earlier depression. Findings pointing to the same conclusion were reached by Abraham Berglund in his study of price behavior before and after the formation of the U.S. Steel Corporation (specifically in 1898 as compared to 1902-14) and by George

CHART III

Stigler in his comparison of the actual to the total possible number of price changes during 1898-99 as contrasted to 1939-40.[6]

Measured on any basis, concentration in the steel industry during 1929-33, while lower than in the years immediately following the formation of the U.S. Steel Corporation, was far higher than in 1890-97. The Commissioner of Corporations[7] states: "In 1890 there were scarcely any consolidations of the modern type in the steel industry. [The industry] was characterized by the competition of a large number of independent concerns." The only area in which concentration was at all noticeable was in the simpler and heavier forms of steel. But even here it took seven companies to account for half of the output, as represented by steel ingot production. According to the commissioner: "These concerns were . . . distinct entities with respect to ownership. . . ." (*Ibid.*, page 65.) In 1937 only four companies accounted for 71.7 per cent of the value of product of open-hearth and Bessemer steel. (TNEC Monograph No. 27, *op. cit.*, page 463.)

Not only was the industry in the earlier depression composed of a "large number of independent concerns"; vertical integration was generally conspicuous by its absence. The Commissioner of Corporations states: "Thus, the production of ore, broadly speaking, was a business by itself, and comparatively few iron and steel companies had extensive holdings of ore lands. . . . Moreover, a substantial proportion of the country's pig iron was produced by 'merchant' furnaces, which sold their product instead of manufacturing it into more finished articles. Even the larger manufacturers of steel bought considerable quantities of pig iron. . . most manufacturers of finished articles purchased their supply of semifinished steel instead of producing it." (*Report of the Commissioner of Corporations*, *op. cit.*, page 66.)

It is true that during the 1890-97 period the steel companies made repeated attempts to control the market through pools and gentlemen's agreements. But it is also true that these loose forms of control proved to be relatively ineffective, tending to disintegrate whenever demand began to fall off. Vernon Mund writes: "During the recession of 1896-97, all of the variously reported pools and price associations appear to have collapsed and the demoralization of trade became acute." (Vernon A. Mund, *Open Markets* [Harper & Bros., 1948], page 163.) (It should

[6] Abraham Berglund, "The United States Steel Corporation and Price Stabilization," *Quart. Jour. Econ.*, November, 1933, George J. Stigler, "A Theory of Delivered Price Systems," *Am. Econ. Rev.*, December, 1949, p. 1152.

[7] *Report of the Commissioner of Corporations on the Steel Industry*, Pt. I, 1911, p. 63. It should be noted that the period under examination in this study antedates the last two years of the century which saw the formation of a number of important consolidations, most of which were, in turn, absorbed by the U.S. Steel Corporation in 1901. (Cf., *ibid.*, p. 79.)

be noted that pools for a number of the industry's most important products were not formed until after the 1890-97 depression had run its course. Thus the structural steel pool and the steel plate pool were not formed until 1897 and 1900, respectively.)

In their final judgments, the authorities seem to be in complete agreement. Speaking of its early years, Myron Watkins describes the industry as "a competitive trade." (Myron W. Watkins, *Industrial Combinations and Public Policy* [Houghton Mifflin, 1927], page 123.) Charles R. Van Hise concludes that "during the period before consolidation, competition had been severe and prices alternately high and low, depending upon the trade conditions and the extent of cooperation." (*Concentration and Control* [Macmillan, 1921], page 113.) The Commissioner of Corporations is explicit: ". . . as a rule the ownership of iron properties was widely scattered and, in this, as in the manufacturing branch of the industry, competition *rather than concentration* was the distinguishing characteristic. . . ." (*Report of the Commissioner of Corporations, op. cit.*, page 66. Italics added.)

The distribution of the copper, lead, and zinc products shown on the lower grid of Chart III is in sharp contrast to the scatter of the iron and steel products. With only one exception—zinc sheets—these nonferrous metals were characterized by greater flexibility in the later than in the earlier depression. It is true that the concentration ratios of manufacturing production for these products are relatively high. It is also true that their prices are extremely flexible. But it does not follow that this association constitutes an exception to Means's argument. The reason lies in the fact that the available domestic concentration ratios for these products substantially overstate the control of the market.

In the first place, these commodities have long been sold on a world market and their prices are immediately responsive to international developments. Hence figures on domestic concentration substantially overstate the control of the market, and the cost position of the US producers accentuates the overstatement. Moreover, they are produced in scattered areas of the world under widely differing conditions, a circumstance which has given rise to numerous conflicts among the different producers.[8] In the second place, concentration figures based on domestic production overstate the actual control of the market because of the important role played by secondary metals: "Copper is

[8] For a discussion of the attempts to establish effective cartels for these products in the later depression, see *International Control in the Nonferrous Metals*, edited by William Yandell Elliott (Macmillan, 1937), Chaps. VIII, X, and XII, by Alex Skelton, and Chaps IX, XI, and XIII by Elizabeth S. May. Similar attempts during the earlier depression are described in the US Industrial Commission, *Report of the Industrial Commission*, Vol. 1, 1900, p. 93, and *Engineering and Mining Journal*, May 18, 1895, and January 5, 1895.

practically indestructible. . . ." In 1930 scrap dealers and secondary refiners supplied 35.9 per cent of the country's copper requirements. In the lead industry, the automobile storage battery reservoir forms "a huge circulating fund"; by 1933 the proportion of secondary to domestic primary lead was 86 per cent, while in zinc the proportion in 1932 was 23 per cent. (Skelton, *op. cit.,* pages 625, 772.) Finally, much of the output of the independent lead and zinc mines can and does find its way to the market through the medium of custom smelters. Inasmuch as these smelters operate on the basis of a fixed margin between the ore price and the refined metal price, it is to their interest "to operate at a high level of capacity, regardless of price." The resulting conflict with the interests of the integrated companies "became apparent from the commencement of efforts to agree on a united policy." (*Ibid.,* pages 727, 711.)

A special factor in the great price decline of copper between 1929 and 1933 was a bit of apparent business stupidity which has few parallels in modern industrial experience: the raising of the price from around 11 cents a pound, where it had remained for several years, first to 18 cents and later for a hectic fortnight to 24 cents. Since industrial output and, with it, the demand for copper were falling rapidly, these prices resulted in a fantastic increase in stocks, and the price subsequently collapsed, dropping to a low of 5.7 cents in 1932. (Cf. May, *op. cit.,* pages 525, 567.)

The final chart, number IV, presents in its upper grid the price changes for four products of the glass industry, two for plate glass (1 and 2) and two for window glass (3 and 4). As between the two depressions, the plate glass items show a great decline in price flexibility and the window glass products a great increase.[9] There is reason to believe that in the former, concentration rose, while in the latter, it fell.

The early growth of the plate glass industry in this country was largely the work of one man—J. B. Ford—who was "an intelligent entrepreneur of the most versatile type." Up to the time when he built his first plant, there were only five plants in the industry, with a combined output of only $355,000. By 1890, there were sixteen plants and the aggregate output had increased more than tenfold, to $5,953,000. Most of this expansion came about as the result of Ford's activities. From the point of view of its effect upon economic concentration, his method of operation was both unusual and significant. After constructing his

[9] Because the consolidation of most of the industry into the Pittsburgh Plate Glass Company took place in 1895, the price comparison for the first depression is between 1890 and 1894 rather than between 1890 and 1897. These first four years of the decade constituted a period of substantial economic decline

first plant, "Ford built one new plate glass works after another, managing each for a short time, *then selling out* to free himself for construction of larger and better plants, representing in every case successively greater capital investment." (Pearce Davis, *The Development of the American Glass Industry* [Harvard University Press, 1949], pages 165, 166. Italics added.) Toward the latter part of the depression of 1890-97, the industry witnessed a great consolidation, out of which emerged the Pittsburgh Plate Glass Company as the nation's dominant producer:[10] "In 1895, through a reorganization, it [Pittsburgh Plate Glass] acquired all but three of the factories making plate glass in the country." (*Ibid.*, page 239.) Since the turn of the century, Pittsburgh Plate Glass has easily dominated the industry. By the twenties the company accounted for approximately 50 per cent of the United States output, "at which point it appears to have been maintained." (Burns, *op. cit.*, page 224.)

In striking contrast to the plate glass industry, price flexibility in window glass was much greater in the later than in the earlier depression. Obviously, the greater severity of the 1929-33 depression would explain only part of the extensive difference in price behavior. For over a decade prior to the earlier depression the window glass industry in the United States "was ruled by the joint power of the combination of workers and the combination of employers." (Davis, *op cit.*, page 131.) Or as another authority put it: "In no branch of the [glass] industry during the period 1880-1920 did organizations of laborers, employers, and wholesale dealers wield as much monopolistic power for as long a time as did those involved in the production of window glass." (Scoville, *op. cit.*, page 217.) Through Local Assembly 300 Knights of Labor of the Window Glass Workers of America, rigid limitations were imposed as to the amount of output to be "blown" per hour, per week, per month; on the number of months worked per year, which were gradually reduced by 1885 to nine; on the amount of the labor supply, etc. "It is thus clear from the beginning of its national history, L. A. 300 assumed rigid control of window-glass production." On their part, employers were organized into the American Window Glass Manufacturers Association, which, it is said, "decided how many and what works should be closed, what wages should be paid (in negotiation with the national union) and what prices charged."[11] In 1895 a

[10] Its predecessor was the New York City Plate Glass Company, organized in 1881. The name was changed to Pittsburgh Plate Glass Company in 1883. But it was not until 1895 that the consolidation was effected. (Warren Scoville, *Revolution in Glassmaking* [Harvard University Press, 1948], p. 239.)

[11] Davis, *op. cit.*, p. 130. For a further description of the detailed methods of restriction used by the union, see Department of Commerce, *The Glass Industry*, Misc. Series No. 60, 1917, pp. 291-293.

selling pool was founded, known as the American Glass Company, which handled the business of 85 per cent of the window glass factories then in existence. The effect of this new organization upon the price level was almost immediate. "The formation in 1895 of the selling pool . . . permitted the price of windowpanes to be pushed upward, not only absolutely, but also relatively to other commodities." (Davis, *op. cit.*, page 176; Scoville, *op. cit.*, pages 230-231.)

In the later depression, concentration in window glass, as compared to other industries, was still relatively high. But as compared to the almost complete control of the industry during the latter part of the 1890-97 depression, exercised through the selling pool and supplemented by the long-standing bilateral organization of workers and employers, the market did not appear to be as tightly controlled. The skilled workers and the use which could be made of their organization to control output had been eliminated by the introduction of mechanized processes. In 1937 it took four companies to account for 85 per cent of the production of window glass. (TNEC Monograph No. 27, *op. cit.*, page 455.) Hence, it would appear that the increase in price flexibility of window glass was accompanied by a lessening of the control of the market.

As will be seen from the lower grid of Chart IV, the showing for anthracite (1 and 2) resembles that of the window glass industry. Prices dropped much more in the later than in the earlier depression; indeed, in the earlier period they rose. From the available information it would appear that the direction of change in concentration parallels that of the window glass industry.

For a considerable period of time prior to 1890, the anthracite industry had been under the close control of a few railroad companies which, through the issuance of large amounts of securities, had been able to purchase most of the anthracite-bearing lands. Concentration of control in this industry is facilitated by the fact that these deposits are highly centralized in a small area, comprising less than five-hundred square miles, in five counties of northeastern Pennsylvania. By 1890 the so-called "line" companies—those owned by the railroads—had obtained possession of more than 95 per cent of the anthracite reserves. (TNEC Monograph No. 21, *op. cit.*, page 179.) The industry had also experienced nearly two decades of attempts to control the market involving at least five separate agreements, or "combinations" as they were termed. (Cf. Eliot Jones, *The Anthracite Coal Combination in the United States* [Harvard University Press, 1914], page 229.) Like most such arrangements, the history of these agreements was typically one of temporary success, followed by recurrent noncompliance and breakdown, and then by reconstitution on a somewhat modified basis.

COMPARISON OF PRICE FLEXIBILITY IN TWO DEPRESSIONS 1890-97 AND 1929-33
CHART IV

Although other factors were occasionally involved, the root cause of their failure was invariably the same; namely, the refusal of one or more of the leading companies to remain content with its allotted share of the market. (Cf., *ibid.*, pages 43, 45, 48, 50.)

During the depression of 1890-97 there were two organized attempts to control the market, only the latter of which is relevant to the price comparison used in this analysis. This second attempt resembled in form the old allotment plan but differed in substance in that on this occasion the different producers generally did abide by their allotted shares of the market: "The division of tonnage was well adhered to by the companies. *In every case the deviation of shipments from the percentage allotted was less than one-half of one per cent.*" (Jones, *op. cit.*, page 56. Italics added.) The success of the plan is indicated by the increase in price, the average price of stove coal rising from $3.13 a ton in 1895 to $3.79 in 1896 and to $4.01 in 1897. (*Ibid.*, page 56.)

As contrasted with the earlier period, the most important difference in the later depression was the loss in position of the line companies to new large independent firms "who could not be controlled." (William R. Pabst, Jr., "Monopolistic Expectations and Shifting Control in the Anthracite Industry," *Review of Economic Statistics*, February, 1940, page 52.) With the oncoming of the depression, the line companies began to reappraise the value of their tremendous holdings: "The practice of leasing mines to independent operators, large and small, in the years after 1929 indicates the speed with which the line companies hastened to take account of the revisions in expectations." Between 1929 and 1933 the large independents increased their share of the industry's production from 24.8 to 37.7 per cent. For the most part the important independents were new entrants: "The development of these new large independent producers is the most important element of the internal change of the industry." (*Ibid.*, pages 52, 47, 48.) As compared to earlier periods the control held by the line companies had declined substantially. By 1937 the eight line companies accounted for only about 60 to 65 per cent of total production; in 1923 their proportion had been 74 per cent[12] and in earlier years considerably higher. Thus there can be little doubt but that the increase in price flexibility in the anthracite industry was accompanied by a decrease in concentration.[13]

[12] TNEC Monograph No. 21, *op. cit.*, p. 181. These percentage figures are not strictly comparable with those presented by Pabst since, following the Anthracite Coal Industry Commission, he designates ten firms as line companies, whereas TNEC Monograph No. 21 designates only eight as line companies.

[13] Pabst advanced the argument that although (*a*) "the line companies appeared to be acting in coordination," (*b*) "they appeared to be holding their prices up and letting production fall, bringing capacity in line with their potential demand," (*c*) "their adjustment

Two decades ago, one of the liveliest issues engaging the attention of economists was price rigidity—particularly the relationship between such price behavior and the structure of industry. Largely because of the war and the subsequent abnormal sellers' markets, the issue seems to have been all but forgotten. The industry-by-industry analysis presented in this paper shows that in four major areas of the economy—farm products, foods, textiles, and lumber—prices were flexible in both depressions, as would be expected from Means's argument, since these areas were generally atomistic in both periods. Moreover, the analysis also shows *increased rigidity, following the concentration of the industry*, in such diverse fields as iron and steel, salmon, salt, biscuits and crackers, molasses, matches, plate glass, window glass, and anthracite (the last two in an inverse manner).

Now that the abnormal postwar sellers' markets appear to have come to an end, it may be highly appropriate for the economic profession to focus its attention again on the subject of price inflexibility. If one agrees with this observer that price rigidity during a downswing is economically injurious, the reasons for examining the factors which might contribute to such price behavior are self-evident. The results of this analysis, taken in conjunction with Means's own findings, suggest that one of those factors—and an important one at that—is economic concentration. But even if one holds that price rigidity is not harmful, further examination should be made of the manner in which such prices are set, the considerations behind their determination, the economic effects of their being imposed at alternative levels, etc. If this paper has done no more than to contribute to a reopening of interest in this whole question of depression price behavior, it has more than served its purpose.

---

was the kind that might be expected from the dominant enterprises in a declining industry beating an ordered, strategic retreat," and (*d*) "the independents . . . were acting on the whole in a way to justify the term 'competitive irrationality,'" nonetheless ". . . the hypothesis that the shifting control in the industry results from differences between the adjustments of competitive and monopolistic producers, in respect to prices and costs, cannot be maintained." The reason that it cannot be maintained, he holds, is that "the individual independent operators did not step up production, but generally, from the largest to the smallest, lost in about the same degree as the line operators." What he is referring to is the behavior of those independents who were in business throughout the period. His observation does not hold true, as he recognizes, of the "new" independents, who accounted for most of the gains shown for the independent group. These firms greatly increased their output and in general followed the norms of competitive behavior.

FULL EMPLOYMENT, WAGE FLEXIBILITY, AND INFLATION[1]

By KENYON E. POOLE
Northwestern University

I

Considerable disagreement has existed during the years since World War II over the extent to which unions have succeeded in exercising an independent effect on wages and prices. Since unions are a form of monopoly, they are in a position to affect the supply of labor.[2] Consequently it is generally agreed that wage rates under unionism are bound to be different from what they would be under a system of unilateral wage changes granted by employers to an atomized labor force. But this measure of agreement does not carry us very far in evaluating the inflationary effect of unions. What we want to know is (1) whether or not union policy contributes to the intensity of the inflationary spiral during a period of partially or entirely deficit-financed military spending, (2) whether it will do so during a peacetime boom in the private sector of the economy, and (3) whether union policy can contribute to a creeping inflation independently of either peacetime or wartime boom spending, and in the absence of a legacy of liquid assets from a previous inflationary period. The present paper is concerned primarily with the third of these alternatives, and thus considers the impact of a rise in cost on the level of spending. Care must be taken to bear these three cases separately in mind when facing up to the question whether or not the existence of unionism injects an "inflationary bias" into the economy.

The effect of unionism on the price level is one aspect of the broader question of the impact of changes in costs on prices and sales. The four

[1] I am indebted to the Graduate School of Northwestern University for aid for research and to the Brookings Institution for its interest in a broader project of which this is a part. Allen Vander Meulen, Jr., was very helpful in the preparation of this paper.

[2] The literature is full of warnings that unless the monopoly power of labor is curtailed or unions use their power with restraint, free enterprise will be jeopardized. Cf., for example, J. M. Clark, *Alternative to Serfdom;* the papers by G. Haberler, E. Chamberlin, and J. M. Clark in D. M. Wright, *The Impact of the Union* (Harcourt, Brace, 1951); and C. E. Lindblom, *Unions and Capitalism* (Yale University Press, 1949); and the criticism by J. Dunlop, *Am. Econ. Rev.*, June, 1950. The evidence for this contention does not seem very strong. Demand inflation is responsible for much of the upsetting effect on democratic institutions that has often been attributed to the power of the unions. Labor may on occasion find itself in a strong position politically, but in a healthy democracy any tendency to make excessive use of a strategic political position ought to produce its own corrective.

links in the chain connecting changes in wage rates with changes in the demand for labor are the relation of wage rates to labor costs, of the latter to total cost, of total cost to price, and of price to sales and output. (Cf. A. M. Ross, *Trade Union Wage Policy* [University of Chicago Press, 1948], page 80.) Clearly there is great variation in the free play in these links from firm to firm and from industry to industry as well as over time.

In assessing the likelihood that unions can force the pace of inflation, the first step is to weigh the effect of a rise in costs on prices. It is accepted that if cost rises are to be reflected in prices, assuming productivity and the volume of transactions unchanged, the rise in cost must cause an increase in the quantity or the velocity of money or both. It has often been pointed out that the world's major inflations have not originated on the cost side. They have resulted either from a bank-financed boom in private investment or from government deficit spending in time of war. Subsequent further inflationary movements, after the initial burst of private or public spending, are likewise to be attributed to the demand side. The public, in drawing upon its liquid assets amassed during the boom, is merely perpetuating a demand inflation. Experience in past inflations, however, is not relevant to the question whether, under conditions of long-continued full employment, the economy would have an inflationary bias in the absence of a legacy of liquid assets from a period of bank-financed inflationary spending.[3] Much of the discussion of inflationary bias in recent years is of limited application, because it tacitly assumes some such period as the decade following World War II. Certainly we are interested in the extent to which the existence of unions and other monopolistic organizations act to accelerate price rises during such a period, particularly if circumstances should dictate years of inflationary government and business spending. But we are also interested in the role of costs—in particular, wage costs—during periods in which demand inflation is not present.

In the present context, an economy is said to have an inflationary bias if, in the absence of a demand inflation, increases in costs set in motion a train of events that lead directly or indirectly to the increases in liquid assets and spending which are necessary to permit the rise in costs to be passed on in higher prices. The bias is much more marked if the initial rise in costs and prices establishes an expectation of a still further rise. A cost rise that is limited to a particular firm or industry is likely at most to encourage a temporary increase in borrowing to meet higher working capital charges. If, however, the rise in cost is

[3] Cf W A. Morton, "Trade Unionism, Full Employment and Inflation," *Am Econ Rev*, March, 1950, and the comment by M. Bronfenbrenner, *ibid*, September, 1950

widely diffused throughout the economy, firms might be prepared to increase borrowing (and banks to permit them to do so), on the assumption that a higher rate of borrowing is appropriate to a higher level of aggregate investment. Consumers likewise may respond to the rise in prices by reducing savings or by expanding installment borrowing. Whether savings are reduced or installment buying increased, the result may be an indirect rise in commercial bank lending, in the former case to businessmen who had previously been borrowing these savings and in the latter to the merchants who are enlarging their credits to customers. These responses, however, do not point in the direction of a spiral of inflation, or even of creeping inflation. Indeed they may be merely temporary, in which case the price level must fall back again to its previous level.

The probably rare appearance of a pure cost inflation in the private sector, however, does not eliminate the possibility that the reaction of the government to cost rises may be calculated to freeze higher costs into higher prices, or even to precipitate an inflationary spiral. If the government feels constrained to counteract any extensive cost-induced unemployment with work-creating fiscal measures, prices may reach equilibrium at a higher price level or may conceivably interact with costs to set up an inflationary spiral. Is there evidence that there has been such an inflationary bias in this country?

If the consequence of a rise in costs were known beforehand to be an immediate and fairly substantial decline in employment, there would seem to be no doubt that an inflationary bias could exist. For no government would dare to refrain from forestalling this unemployment by creating deficits. In practice, however, unemployment usually makes its entrance gradually. Thus a period of doubt is ordinarily experienced, during which debt-conscious administrations are likely to be hesitant to undertake what may prove to have been a premature program of deficit spending or tax reduction. If they wait very long, however, the downswing may become so pronounced that the problem would be one of avoiding deflation rather than inflation.

It seems likely that the view prevalent during and after the depression—namely, that henceforth governments must take remedial steps immediately on the appearance of "Beveridge" unemployment (fewer vacant jobs than unemployed workers)—has been significantly tempered by fears of inflation during recent years. The argument could be made that even if the effect of excessive wage demands were rather considerable unemployment, the probable response in terms of government fiscal policy is hardly likely to have significant purchasing power effects. The unemployment is obviously not "Keynesian," and thus

would not call for action under a Keynesian public works spending program. This type of unemployment is in any case difficult to remedy through aggregative fiscal measures.

Experience in the recessions of 1948-49 and 1953-54 indicates that both Democratic and Republican administrations prefer to react cautiously to moderate downturns. Other issues dominate unless unemployment rises above the figure that is generally accepted as "tolerable." But if this is so, presidents would hardly be likely to recommend immediate action against the relatively small and widely distributed amounts of unemployment that may result from an aggressive wage policy. This view receives support from both the Truman and Eisenhower recession programs. Unemployment stood at 6.0 per cent in June, 1949, as compared with 3.4 per cent in June, 1948; and consumer prices had declined by 3 per cent from the August, 1948, high. The President and Congress, however, were more concerned with the impact of tax relief on the level of the public debt than with the elimination of all vestiges of unemployment. Truman's policy was to bank on an early upturn, while merely laying plans for public works in the event of a more serious decline in business activity. It was stated in the "Midyear Economic Report" of July, 1949 (page 6) that "the kind of government action that would be called for in a serious emergency would not be appropriate now." One reason that the Truman administration was loath to adopt antidepression policies in the spring of 1949 was, of couse, the constant fear of a continuation of the inflationary rounds of wage increases that were experienced in 1948. In the absence of such a fear, the possibility does indeed exist that the appearance of even a small amount of unemployment might produce a quick response in the form of intentionally created federal deficits.

The reaction of the Eisenhower administration to the recession of 1953-54 was very similar. Here again unemployment, according to President Eisenhower's statement of August 12, 1954, had risen from 2.4 per cent in July, 1953, to 5.1 per cent in July, 1954. Prices, however, remained virtually stable during this period. The attitude of the administration toward moderate increases in unemployment has been that "the need for constant vigilance and preparedness by government does not, however, justify constant stirring or meddling. Minor variations in activity are bound to occur in a free economy. . . ." (*Economic Report* of the President, January, 1954, page 113.) Evidently both political parties are torn between a desire to avoid an increase in the national debt and the necessity of keeping public reaction toward unemployment below the political boiling point.

As the argument stands thus far, it is contended that unemployment resulting from a rise in costs is not likely to be so quickly remedied by

deficit-financed public spending or tax reductions that the economy can be said to have a cost-inflationary bias. If, however, unemployment can be eliminated by a rise in government spending without a rise in the debt, an inflationary bias may nevertheless exist. The fear of deficits as a reason for delay in adopting counteracting measures would disappear. An increase in the size of a balanced budget may be inflationary at full employment, provided the prospect is for a continuing high-level aggregate demand. A part of the additional taxes falls on savings, and it can be assumed that the firms which are denied the opportunity to borrow these diverted savings will turn to the commercial banks. Assuming Federal Reserve and commercial bank co-operation, the probable result is a rise in total public plus private spending under inelastic conditions of factor and commodity supply and an upward pressure on prices. The situation is different, however, when unemployment has already appeared or even if a downturn from full employment conditions seems imminent. Taxpayers are indeed still likely to attempt to maintain consumption levels by reducing savings; but it is now probable that at least a part of these savings would have been voluntarily relinquished by businessmen who anticipate a further downturn. Consequently the hoped-for increase in bank-financed private borrowing will not materialize, and no basis exists for the contention that in these circumstances a rise in costs would generate the additional purchasing power necessary to sustain it.

II

A rise in wage cost at full employment in the absence of a demand inflation may or may not establish the conditions for a cost inflation. It could have one of four different effects on the price level.[4] Prices might fall. They might remain at the same level as before. They might rise uniquely with the rise in wage rates. Or an inflationary wage-price spiral might be set in motion. The first of these alternatives might occur if under stable full employment conditions a wage rise suddenly occurred which caused business losses and initiated a contraction of investment, incomes, and prices. In both 1921 and 1930 union wage rates

[4] Much disagreement exists over the consequences of creeping inflation One view is that continuously rising prices and incomes cause distortions that must relatively soon lead to a crisis and depression Opposed to this is the contention that we must resign ourselves to a long-term upward price trend, and that a major problem is to avoid hyperinflation. The view that a persistent inflation is sure to build up gradually a resistance that will halt the upswing stresses such factors as changes in the level of productivity, the rate of new investment, the foreign balance, money market liquidity, the rate of interest, and the elasticity of price expectations. Cf. D. Copland, "The Full Employment Economy, with Special Reference to Wages Policy," *Oxford Econ. Papers*, October, 1953; G Haberler, *op. cit*; and W G Broehl, "Trade Unions and Full Employment," *So. Econ. Jour.*, July, 1953. For the view that in a full employment economy a moderate inflation might be expected for years to come, see S. Slichter, *Business Week*, October 25, 1952.

continued to rise after the downturn. (Cf. W. H. Chartener, *Wages in Deflation*, Editorial Research Reports, June 13, 1949.) The second alternative is a possibility when a consequence of the higher wage rates is either a decline in the rate of return to other factors or a reduction in costs in response to the pressure on firms to increase efficiency. The third, which has been called "static inflation," can occur when, assuming an elastic money supply, price policy is geared to changes in cost. It can also occur as a result of a conscious fiscal policy designed to retard inflation. The fourth—the inflationary spiral—could be initiated by a price rise associated with a wage rise if the increase in worker consumption spending were not offset by a decline in investment and if an interaction were set up between costs and prices. It is proposed to say a few words about the third and fourth of these cases.

The literature is well stocked with models that demonstrate the conditions under which, when wage rates rise, prices must rise by the same amount.[5] Moreover, the frequent publicity accorded in the postwar years to the quick price responses to wage increases has appeared to give empirical content to the findings of these models. Inferences from neither the models nor the empirical evidence, however, have general significance. The former are limited either by the restrictive assumptions of the static cost and demand curves of the individual firm or by those of equally restrictive aggregate economic models. Inductions from the empirical evidence, again, are usually complicated by the presence of demand inflation and are susceptible to the dangers of reasoning *post hoc, ergo propter hoc*. Many instances can be found in which price rises in response to wage increases have later been followed either by price reductions or by the omission of price rises that would otherwise have been made. The wide range of possibilities is illustrated by two examples selected almost at random from recent experience. In France, wholesale prices and wages responded quickly to the 15 per cent rise in minimum wages enacted in September, 1951. Because the rise was general and the underlying situation inflationary, increases in cost could be quickly passed forward and the entire wage-price

[5] Reference may be made *inter alia* to the treatment of wage-price-profit relationships in the *Treatise on Money* and the *General Theory*. See also A. Lerner, AEA *Papers and Proceedings*, May, 1946, p. 331, and the comment by S. Slichter, *The Challenge of Industrial Relations* (Cornell University Press, 1947), p. 79; M. W. Reder, "The Theoretical Problems of a National Wage-Price Policy," *Can. Jour. Econ. Pol. Sci.*, February, 1948, A. Flanders, *A Policy for Wages*, Fabian Tract #281, pp. 31 ff.; A. T. Peacock and W. J. L. Ryan, "Wage Claims and the Pace of Inflation," *Econ. Jour.*, June, 1953; and, with reference to Harrod's model, A. G. Pool, *Wage Policy in Relation to Industrial Fluctuations* (Macmillan, 1938), pp. 116-117. Peacock and Ryan are concerned with the cushioning effects of lags under collective bargaining and under wage escalator arrangements. For an examination of the assumptions under which a wage change will cause an equal change in prices, see T. Mayer, "The Effects of a Wage Change Upon Prices, Profits, and Employment," *Econ. Jour.*, September, 1951

structure tended to be restored at a higher level. By contrast, because of the highly competitive nature of the American textile industry, New England textile companies in the same year were not able to pass on wage increases escalated by the rise in the consumers' price index. After the introduction of the cost-of-living escalator in 1951, textile prices dropped, some by as much as 20 per cent between the years 1950 and 1952.[6]

The immediate price response to a rise in wage rates will depend on the evaluation by the firm of the market situation, in conjunction with the pricing practices of the industry, as well as on the importance the firm may attribute to the impact on public opinion of a price rise made directly in response to a rise in wage cost. One element in public opinion is the reaction of the union, whose attitude in part reflects its opinion of the effect of higher prices on real wages and employment. Its objections, if any, are likely to have their greatest effectiveness in a delicately balanced political situation, when business may be encountering difficulty in explaining a high rate of profit. Even then firms may be able, in some industries at least, to protect themselves with labor-cost and materials-cost contracts, which permit automatic price increases with a minimum of publicity. However, it is likely to be true that in the absence of a demand inflation the passing forward of cost increases is not likely to become a political issue. The price increases are simply too unimportant.

For several reasons a rise in cost may not be followed by a rise in price. For example, if full employment has continued for some time, markets are likely to have become more favorable to buyers. Unions may, however, have the power to achieve further wage increases. The effect on investment may be negative and prices may fall. Again, if a wage bargain is settled on the expectation of a price rise, the disappointment of this expectation may mean that wage increases have been made that cannot be passed on in higher prices.[7] Gains in productivity make possible wage increases without the need for corresponding price rises.[8] It is probable that the spread of industry-wide

[6] H. C. Eastman, "The Economic Effects of the French Minimum Wage Law," *Am Econ Rev.*, June, 1954, pp 375-376; company testimony, Bates Arbitration case, March 3, 1952

[7] Although cases are rather rare in which explicit account is taken of anticipated price rises in wage agreements (an example is the Austrian 5th price and wage agreement, July, 1951; cf. Bert Zoeteweij, "The Adjustment of Wages to Changes in the Cost of Living," *International Labor Review*, July-December, 1952, p. 101), the expected course of prices is a factor which is always present in wage bargains.

[8] During the defense period, up to the spring of 1941, wage increases appear to have been more than offset by increases in productivity. (BLS Bulletin 1009, Chap. III, "Development of Wage-Price Policies," H. M. Douty.) For an attempt to test the proposition that it is difficult in competitive industries for workers to get productivity increases translated into higher wages, see A. M. Ross and W. Goldner, "Forces Affecting the Inter-industry wage Structure," *Quart. Jour. Econ.*, May, 1950.

bargaining, if characterized by pattern bargaining, would result in many wage increases that could not be followed by compensating price rises. Competition from foreign producers may prevent price markups. The conclusion seems to be warranted that the variety of circumstances in which wage and other cost increases may occur is so wide that wage and price flexibility at full employment has to be studied largely on the basis of individual cases.

In the event that a rise in wages or other costs is reflected in increased products price, the possibility exists that an inflationary spiral may be initiated. An important cushion against the spiral effect, however, is the absorption of part or all of any induced increase in the money supply by the initial rise in prices. This could result in equilibrium at some higher price level. The effect can be produced artificially by taxing the desired amount of purchasing power out of the income stream, provided allowance is made for the possible inflationary effects of the additional taxes.

Equilibrium at a higher price level would not result, however, if two or more escalators interacted rigidly (for example, a cost-of-living escalator and agricultural price parity) at each step in the process inducing the increase in the money supply required to permit an inflationary spiral. The marked increase, in recent years, of escalator devices designed to guarantee shares in the national product multiplies the chances of a cost-push inflation that is separate from the demand-pull of an inflated money and asset supply. It is quite possible that in an economy characterized by the widespread use of escalators, the monetary authorities would find it difficult to resist political pressure to adapt the money supply to the requirements of a constantly rising price level.

Yet it is questionable that the general adoption of escalators would in practice contribute significantly to a spiraling inflation. A striking feature of these devices is the readiness with which, in some foreign countries, at least, steps have been taken to soften their rigidities in the event that they threaten to produce unwanted economic effects. For example, particularly when governments participate with firms and unions in developing an escalator agreement, a number of escape clauses and limitational devices have been concocted to retard its operation in the event of the threat of an inflationary spiral, though of course by no means all have been used in any one escalator agreement. Among these devices are the restriction of escalation to the minimum wage or to the basic wage, escalation of only a percentage of the basic wage, ceilings on escalation, limitation through price controls, devices for delaying escalation, lags between the collection of

price data and the application of the consumers' price index in the escalator formula, and so on.

In addition to those limitations on escalators that are in part intended to minimize the danger of an inflationary spiral, cushioning may also occur by virtue of the heterogeneous purchasing power effects of cost-price rises. The more numerous the escalators, the more ambiguous are the possible purchasing power effects. The probability increases that they are not all in the same direction, but by partially neutralizing each other, tend to damp the upward impulse. Some escalators tend to encourage consumption, but at the same time they may cause an increase in cost that discourages investment. Other escalators may preserve profit rates at the expense of consumption. The multiplicity of escalator arrangements makes it very difficult to draw conclusions. These mechanisms range from wage cost-of-living and productivity escalators, through agricultural parity formulas and the formidable array of business price markup devices, to more novel contrivances like price-index bonds and proposals to escalate social security benefits for changes in the cost of living. In addition, there are a number of special types of rigidities which probably should not be classed as escalators, such as price leadership, horizontal wage (or pattern) escalation, equalizing tariffs, and the like. Thus we cannot say for sure that an escalated cost rise, even when supported by a co-operative monetary policy and magnified by interaction with at least some other types of escalators, will necessarily give rise to a spiral of inflation. Incidentally, it would be interesting to study the circumstances in which escalators tend to breed escalators. The more widespread the practice of escalation, the smaller the reservoir out of which the protected groups can hedge themselves against inflation and the greater the pressure on all groups to participate in the protection. Under certain assumptions, the result could be an accelerated rate of adoption. Again, rising real incomes and the increasing importance of the small saver provide fertile ground for fostering the popularity of parities and escalators.[9]

III

We come now, very modestly, to the question posed at the beginning of this paper: Has there been a tendency either to exaggerate

[9] For the Swedish plan for hedging pensioners against inflation as well as assuring them participation in productivity increments, see Alan Peacock, "Social Security and Inflation," *Rev. Econ. Stud*, 1952-53, pp. 169-173. The Christiansen Corporation has recently offered employees an issue of cost-of-living debentures, with a ceiling of 150 and a floor at the issue price of 100. (*Management Record,* June, 1953, p. 200.) These are merely random examples of the wide variety of experiments that have been made in many countries, a number of them going back to the early twenties.

or minimize the effects of unionism on wages and prices in the propagation of a cost inflation? If the effects have been exaggerated, have they nonetheless been significant? One is struck by the difficulty of answering this question unambiguously. It is common to make specific comparisons that may have little or no general application. In individual instances it can sometimes be asserted that the direct effect of the union was either to accelerate or retard wage increases. It is more difficult to understand what this proves about the over-all impact of unionism. In arguments intended to minimize the importance of union power to influence wage decisions, the procedure has often been to consider a situation in which, if the union had been suddenly dissolved, wages would have risen more rapidly. This ignores the role of the unions in events up to that moment, and attributes no importance at all to the threat of unionism as a factor affecting wages in nonunionized industry.

An illustration of this type of thinking is the suggestion that collective bargaining may be a less effective way of achieving wage increases than is reliance on the free play of market forces.[10] It is true that unilateral wage increases can be made rapidly, while the reopening of contracts and the process of collective bargaining are more time consuming. But this is no valid basis for evaluating the general effects of unions on wages. Would the same unilateral increases have been made if unions did not exist? Again, wage increases are sometimes made in order to prevent unions from getting a foothold in the industry. Although such raises appear in the statistics on the nonunion side, they are actually attributable to the existence of unions. Another point is that firms are said to dislike to grant wage increases in organized industries because unions will resist wage reductions even if the price level subsequently falls. But, as Slichter points out, even in unorganized industries account must be taken of the effect of a wage decrease on worker morale. More generally, there is no reason to minimize the influence of unions merely because they crystallize employer opposi-

[10] Cf., for example, M. Friedman, in Wright (ed.), *The Impact of the Union*, pp. 204 ff.; A. Rees, "Postwar Wage Determination in the Basic Steel Industry," *Am. Econ. Rev.*, June, 1941; W. A. Morton, "Trade Unionism, Full Employment and Inflation," *ibid.*, March, 1950; Clark Kerr, "Labor Markets: Their Character and Consequences," AEA *Papers and Proceedings*, May, 1950, p. 228; K. Boulding, "Collective Bargaining and Fiscal Policy," AEA *Papers and Proceedings*, May, 1950, pp. 306 ff. The opposite position is taken by Haberler, *op. cit.*, pp. 34 ff.; S. Slichter, "Do the Wage-fixing Arrangements in the American Labor Market Have An Inflationary Bias?" AEA *Papers and Proceedings*, May, 1954, p. 331. For an examination of some of the statistical work done on the effects of collective bargaining (not of the institution of unionism as a whole) on wage rates, see M. Bronfenbrenner, "The Incidence of Collective Bargaining," AEA *Papers and Proceedings*, May, 1954, pp. 297-299. He concludes that the evidence, though partial and contradictory, is in favor of "some slight tendency" for union wages to lead nonunion wages, but that collective bargaining has not had any important effect on aggregate income distribution.

tion to wage increases. Still another argument is that by taking account of local conditions in bargaining, unions are often really accepting the nonunion wage level. But unions could hardly do otherwise than take account of local conditions, along with other considerations.

The fact that union leaders may pursue a go-easy policy has been used to discount the impact of the unions on wage rates. Variations in union aggressiveness have indeed often resulted in important effects on wage rates, and it is possible that union policy could be so moderate that its relative effect is deflationary. (An example that might be cited is the "New Wage Policy" adopted by the AFL when Green succeeded Gompers as president. The tying of high wages to high productivity was associated with a decline in union militancy.) If inflation proceeds at a rate in excess of what is regarded as politically tolerable, union leaders may have to be satisfied with trivial face-saving gains that do no more than preserve their power with the rank and file. In this reaction they are simply yielding, as they must, to the complex of economic and political forces which determine the degree of public support for their policies.

It has often been pointed out that a union characteristic that can contribute to the alleged inflationary bias in the American economy is the fact that labor policies are the product of the internal politics of the unions, and that immediate monetary gains are uppermost in the minds of the leaders, virtually to the exclusion of the welfare of the country as a whole.[11] The argument often goes on to state that union leaders have to bargain for the concessions that will call forth the greatest measure of support from the rank and file. This means, for example, that the employment effects of wage bargaining may be assigned little importance when the leaders are concerned only to command the approval of employed union members or when, in a declining industry, the union is trying to reduce membership. The reverse, however, could just as easily be so and will be so when the leaders have reason to believe that employment considerations are uppermost in the minds of the rank and file. The extremes are illustrated in two recent cases. In their race with the steel workers to upset the government's wage stabilization program during the period 1950-52, the United Miners matched aggressiveness with the United Steel Workers, ignoring the unemployment and short time already existing in the coal industry. On the other hand, the Massachusetts shoe industry

[11] This issue is discussed by, among others, S. Slichter, "The Government of Trade Unions," Chap. 4 in *The Challenge of Industrial Relations;* Broehl, *op. cit.;* J. Dunlop, "The Economic Model of a Trade Union," *Wage Determination under Trade Unions* (Macmillan, 1944), Chap. III; and Arthur M. Ross, *Trade Union Wage Policy* (University of California Press, 1948)

provides an instance in which a union has agreed, under the so-called "grade system," to wage reductions in the interest of reduced unemployment.[12] A more recent example occurred in the summer of 1954 at the Studebaker plant. In intermediate instances, unions have often justified an aggressive bargaining policy on the ground that the employment effects of higher wage rates could be neither predicted nor estimated.

A familiar criticism of the American labor movement is that it lags behind European unions in the appreciation of the effects of its actions on prices and on economic welfare as a whole. There is ground for believing that part of the reason for American labor's self-centered view toward economic matters is the difficulty of arguing convincingly that an aggressive union policy is more inflationary than a supine one. This difficulty is not likely to be removed until more detailed models of the determinants of income and prices have been developed than are now at hand. Another factor that is partly responsible for aggressive union activity in this country is the high productive capacity and relatively favorable international economic position of the United States, which provide a certain amount of slack in the bond between wages and prices. Despite the high level of personal income, the consumer price index has been virtually stable since the end of 1951, and a number of markets have become buyers' markets, as the growth of the merchandise discount houses testifies. The situation has been quite different abroad. In some foreign countries, where the balance-of-payments or investment programs seemed to require it, unions have been very effective in holding down wage rates despite the protests of the rank and file. In assessing these cases, it has to be borne in mind that if the unions had not shown a policy of restraint, direct controls would probably have been imposed. Therefore we cannot say surely that even in these instances the net effect of the unions on wages and prices has been negative.

An illustration of fluctuating union aggressiveness is offered by the experience of Britain. Rising living costs after World War II had led to a more aggressive union policy and in 1947 to the breakdown of the wage-stabilization policy inaugurated in 1940. Yet the unions responded favorably to the government's plea for wage stability in order to avoid worsening the balance of trade. The failure to halt the rise in the cost of living, however, resulted in another shift in union policy a few months later. On balance, over the entire period, the policies adopted by the unions played a part in restraining inflation. (Cf. J. T. McKelvey, "Trade Union Policy in Post-war Britain,"

[12] S. Slichter, "Do the Wage-fixing Arrangements in the American Labor Market Have an Inflationary Bias?" AEA *Papers and Proceedings*, May, 1954, p. 342; J. P. Shultz and C. A. Myers, "Union Wage Decisions and Employment," *Am. Econ. Rev.*, June, 1950, pp. 364 ff.

Industrial and Labor Relations Review, October, 1952.) In Germany, too, the unions have for many years supported a policy of low wages in the interest of both the export market and a high rate of capital formation. Although (as the strikes of August, 1954, have indicated) the attitude of the unions necessarily stiffens after many years of abnormally low wages, the high proportion of Germany's national income that has been saved and invested in recent years is in considerable part testimony to the modest demands of the trade-unions.

Many statistical comparisons between union and nonunion wage rates have been made in an effort to draw general conclusions on the impact of the unions on wages and prices. Unfortunately they may suffer from the fact that union and nonunion wages are interdependent. Partial studies, restricted to a particular industry or period of time, cannot tell us how high wage rates would have been if labor had never been organized or what they would be if labor policy were integrated under a unified labor movement.

There is, to recapitulate, one set of circumstances in which creeping inflation, which might develop into an inflationary spiral, would be definitely attributable to the power of the unions. At full employment, even in the absence of a demand inflation, unions would be strong; and widespread, aggressive wage demands could be responsible for adversely affecting cost-price relationships to the point at which unemployment developed. If the unemployment were very substantial and if the government responded with deficit-financed re-employment measures, full employment might be preserved at the cost of a constantly rising wage-price level. But experience under neither Democratic nor Republican administrations provides a basis for a fear that this is likely to occur. The opinion is ventured here that even if a labor-oriented administration were to adopt this policy, long before the inflationary stage was reached the opposition of nonlabor political elements would have forced its surrender.

IV

Whatever doubts may be raised over the likelihood of a pure wage-cost inflation, past experience with demand-cost spirals indicates that under certain circumstances aggressive union policy can be expected to play a part in the chain of events that contribute to inflation under full employment conditions. A number of proposals have been made to eliminate this inflationary effect of unions. In general, however, they are unsatisfactory, for either they do not hold forth much promise of success in the foreseeable future or they threaten to produce undesirable economic or political effects. One suggestion is to protect labor through cost-of-living subsidies, avoiding inflation by using progressive taxation to prevent effective demand from outrunning supply.

Apart from the narrow limits to the further use of redistributive taxation and the possibility that investment and output in the future would be adversely affected, this plan does not provide unions and union leaders a reason for existing. Many economists believe that in a free enterprise economy, unions are an indispensable element in the multilateral monopoly struggle for shares in the national product.

Another suggestion is to control prices, leaving it to the employers to deny the wage increases that would eat into profits. (Cf. Gösta Rehn, in Ralph Turvey, editor, *Wages Policy Under Full Employment* [Hodge, 1952], page 49.) Why should the business community give political support to such a suggestion, unless employer resistance were backed by a far severer Taft-Hartley than advocates of the proposal would probably be prepared to countenance? A milder version is for the public in some sense to "reserve its approval" for the employers who oppose excessive wage claims. This proposal has no operational usefulness. It would be better to permit the public to act in the only way it can; namely, by turning away from labor at the polls. Some proposals make their appeal to the union itself: learn to use monopoly power with restraint and thus avoid government control; do not make the union leader too dependent on the favor of the rank and file and thus grant him a measure of freedom for statesmanship; or deposit part of the responsibility for wage policy in the hands of the government. In cases of national emergency, to be sure, an appeal can be made to the union on the basis of public interest; for example, acceptance of a policy of wage and price restraint in order to avoid devaluation or of a low wage policy to encourage a rapid rate of business saving and investment. The general criticism of these suggestions is that except during an emergency they are difficult to implement. Where should the line be drawn? If union leaders are too independent of the membership, the spirit goes out of the unions; and if too dependent, a highly aggressive wage policy may be unavoidable. And what record is there of a power group imposing restraints on itself?

More novel, and probably not very seriously meant, proposals are such devices as: a series of sudden price deflations, engineered in order periodically to get down the whole wage-price structure without the discouragement to investment and consumption that is associated with a slow deflation; the stabilization of the prices of basic commodities by the commodity money plan; and the wage-money plan. (See Boulding, *op. cit.*, pages 318-319.) Still another expedient would be to immobilize a part of increases in wages through some form of profit sharing, thus increasing the proportion of national income devoted to saving and investment. A. Vermeulen ("Collective Profit Sharing," *International Labor Review*, June, 1953) offers a plan for restraining

labor costs in the interest of long-term investment acceleration, while avoiding the increasing inequality of wealth which he believes is ordinarily associated with unaggressive union policy.

V

Because of the rather limited prospects for the acceptance and fruitfulness of any of the above proposals as a permanent defense against cost inflation, it might be worth while for economists to take a second look at the circumstances in which a prolonged creeping inflation, not attributable to demand, is possible or probable. Observers are divided on this point; but there is little in our past experience that leads one to suppose that in the absence of wars, prices would be likely to rise indefinitely. If, however, prices are not likely to do so, the case is weakened for taking seriously any of the doubtfully viable proposals that have been made to soften the wage demands of unions.

Again, there is need for a greater measure of agreement on what is meant by the "limits of tolerable inflation." The concept has no precise meaning, either economically or politically. Within these limits, such inflation as might occur would, by definition, not be worth combating. At the same time the undesirability of an excessive amount of creeping inflation is beyond dispute. The evaluation of alternative meanings of the concept is outside the scope of this paper, but it is suggested that no meaningful definition is possible without allowing for the institutional changes that can be expected to occur as a result of a gradual inflation. The limits of tolerable inflation tend to be extended by the manufacture of devices for hedging various groups against a secular price rise. Thus the argument that bondholders, for example, would resist a gradual expropriation by a fall in the purchasing power of money has to be evaluated in the light of the possibility of escalating debt obligations with a cost-of-living index. Similar defenses might be erected to protect insurance policy holders, social security beneficiaries, and persons with relatively rigid earned incomes. However unlikely the general adoption of these devices in this country may appear on the basis of past experience, the picture might alter considerably if we were confronted with continuous inflation. Quite a different view is that the tremendous growth in fixed claims in recent years, when projected into the future, may strengthen inflationary sentiment among the active earning segments of the population, as well as on the part of those politicians who are concerned to bring about a rise in the proportion of national income taken by government factor purchase expenditures. In a society in which some groups favor inflation and others oppose it, the outstanding characteristic of the limits of tolerable inflation would appear to be their variability.

DISCUSSION

GIDEON ROSENBLUTH: Mr. Blair's revival of an old controversy is most timely. With the decline of agricultural prices in recent years and the appearance of "rolling readjustment" in business conditions generally, there is renewed public interest in the apparent rigidity of certain prices. The paper is also timely in terms of the history of economic thought. Gardiner Means argued in the thirties that concentration of market control had increased, that price rigidity had increased, and that the latter trend was due to the former. Critics soon produced evidence to show that price rigidity had not increased since the nineties or even earlier times, and more recent studies have suggested that concentration has not increased in the last fifty years. Surely the time was ripe for someone to point out that the denial of the first two parts of Means's thesis could be construed as support for the third. If neither concentration nor price rigidity had increased, the two might well be related.

Blair's method is novel and ingenious, and he has given us a number of most interesting case studies. Information, both qualitative and quantitative, from a great variety of sources, has been skillfully combined and brought to bear on the difficult question of the trend in concentration. Of particular interest is the discussion of the degree of market control in the period preceding the great merger movement—an area still largely unexplored.

Can we regard Blair's findings as establishing that concentration is a significant factor making for price rigidity in the American economy? To answer this question I should like to discuss briefly the interpretation of the findings and the nature of the sample.

The essence of Blair's new approach is described in his paper as follows: ". . . contrasting a product's price behavior in two depressions—before and after the industry had become highly concentrated."

This method is applied directly to only two industries: steel and plate glass. Other industries are discussed, either in order to provide a backdrop (farm products, food, textiles, and lumber) or to provide a contrast (copper, lead, zinc, window glass, anthracite). It is doubtful whether results based on a sample of two industries can safely be generalized. Moreover, the interpretation of the results for steel and plate glass is not beyond question. The steel industry is well known for discrepancies between quoted prices and actual terms of sale, and Nelson found evidence of a similar discrepancy (though probably less important) for plate glass (Appendix 1 of the National Resources Committee study, *The Structure of the American Economy*, 1939, pages 182, 183). Blair presents evidence to show that secret discounts were not unknown in the earlier depression. But if discounts are important and variable, the quoted prices used by the Bureau of Labor Statistics are not a reliable guide, and the fact that we do not know whether discounts were more important in the second depression than in the first surely cannot increase our confidence in the reliability of the price data.

The price behavior of plate glass suggests an additional difficulty. It is common practice to measure price flexibility, as Blair does, by the price decline between two reference dates common to all the price series studied, and not by the decline in each price between its own specific peak and trough. This must mean that a spurious impression of rigidity is created for those series that do not closely coincide with the general business cycle in their fluctuations. Surely a price should not be called rigid merely because the market forces that cause it to fluctuate do not exactly coincide in their timing with those influencing other prices. Plate glass would appear to be a case in point, since the two price indexes which declined by only 4.3 per cent and 4.8 per cent, respectively, between 1929 and 1933, fell by as much as 30 per cent and 32.4 per cent between 1929 and 1935.

It may be argued that this is too pessimistic a view of the general significance of the findings. The number of industries in which increasing concentration is found to be associated with increasing rigidity is, after all, in fact greater than two. In addition to steel and plate glass, there are canned salmon, salt, soda crackers, molasses, and matches—all of which are discussed in some detail. But these five industries were selected by a process that involves some bias. They were singled out for special study because they displayed increasing rigidity, in contrast to the majority of industries in the foods and lumber groups. If all the industries in these groups (and in the textiles and farm products groups) had been examined with equal care, one might have found a considerable number with increasing concentration and constant or decreasing rigidity. There are seventy-five products in the study with constant or decreasing price rigidity for which concentration change was not specifically examined. One cannot simply assume that none of them would show increasing market control on closer study.

It may be further argued that acceptance of the hypothesis that concentration and price rigidity are related should not be made to depend on cases of increasing concentration alone. Are there not cases in which decreasing market control is associated with decreasing price rigidity?

Evidence is presented suggesting decreasing market control in two industries: window glass and anthracite. These two industries also display a greater price decline in the second depression than in the first. But, as pointed out by Blair, we cannot regard this as evidence of decreasing rigidity, owing to the greater severity of the second depression. We have, in fact, no way of distinguishing between cases of constant price rigidity and cases of decreasing price rigidity.

The great majority of the industries included in the study have constant or decreasing price rigidity and the author suggests that there has been no significant change in concentration. (This applies to the farm products, foods, textiles, and lumber groups, as well as to the copper, lead, and zinc products.) These findings are of course consistent with the hypothesis that market control leads to price rigidity. But they are equally consistent with the hypothesis that market control has nothing to do with price rigidity, and that neither of them changes much over time.

I have said enough to suggest that the findings of this paper cannot be

generalized unless a larger number of industries can be found in which decreasing or increasing concentration and price rigidity can be clearly identified and the association between them studied. There is room for further research.

If further investigation confirms the existence of a correlation between increasing concentration and increasing price rigidity, other possible influences on the amplitude of price fluctuations would have to be considered in order to determine whether there is in fact a net influence of concentration on rigidity when other factors are held constant. For example, the studies that have demonstrated a close relation between price rigidity and rigidity of direct costs cannot be ignored (e.g., A. C. Neal's study, *Industrial Concentration and Price Inflexibility,* 1941). Hence the movement of direct costs in 1890-97 and 1929-32 ought to be compared in the industries under study. I shall consider some other factors later in this discussion.

There would perhaps be less resistance on the part of many economists to the acceptance of the idea that concentration leads to price rigidity if they were given a good theory to explain why this should be so. It is true, of course, that price rigidity would not exist under conditions approximating perfect competition. At least this is true if rigidity of price is measured in relation to average costs. Hence some degree of market control is necessary for price rigidity. But what has not been shown is why those possessing market control should find price rigidity desirable.

There have of course been attempts at such a demonstration. One old favorite, the kinky oligopoly demand curve, has, I think, been adequately dealt with by Stigler in his article in the *Journal of Political Economy* in 1947. Another is the idea that monopolists dislike the unfavorable publicity that would result from a rise in their selling prices, and do not lower prices in depression for fear of having to raise them again. This hardly seems plausible when one considers the great volume of unfavorable publicity accorded the alleged price rigidity of products made by large corporations in the thirties.

I find it more reasonable to believe that some of the conditions that make price rigidity desirable (i.e., profitable) have nothing to do with market control (though of course firms can only adjust to them if they have some market control) while others, which are related to market control, apply only to a limited number of cases. Hence one would expect the correlation between concentration and rigidity of price in relation to cost to be significant but very weak. This is in fact what A. C. Neal's careful study shows and is consistent with Means's findings and those of the present paper.

Among the first group of conditions, I think the desire to minimize cyclical fluctuations of demand is important. This would help to explain not only actual cases of price rigidity but also the many cases in which rigidity of the quoted price is combined with flexibility in the actual terms of sale (by varying discounts and allowances, credit terms, freight absorption, etc.). The effect of price changes on expectations has often been discussed. If a price reduction, made in response to falling demand, leads to the expectation by buyers of further price adjustments, demand will fall even more rapidly.

Where fluctuating demand imposes heavy costs on the firm (because of heavy overhead and difficulty or cost of producing for inventory), both upward and downward price rigidity may therefore be desirable. Even more desirable may be the policy of keeping quoted prices rigid while varying the actual terms of sale. The rigid quoted price serves to influence buyers' notions of what is normal and to discourage the expectations of further concessions, while changes in the terms of sale accomplish the static adjustment to changing demand.

Empirical studies of price rigidity suggest that this concern with buyers' expectations may be an important factor. Very strong contrasts are found between the rigid prices of durable goods and the flexible prices of nondurable goods. Similarly the rigid prices of capital goods contrast with the flexible prices of consumer goods and producers' materials. (See, for example, F. C. Mills, *Price-Quantity Interactions in Business Cycles* [New York, 1946], pages 46, 47, 54.) Purchases of durable goods, such as capital goods, can be postponed, so that the buyers' price expectations are important, and the cyclical variability on the demand for these products is well known.

Neal has suggested that the sellers' expectations as to future market conditions may promote price rigidity by raising user cost in depression. Since user cost is a more important factor in capital intensive industries, it may be worth while to investigate whether capital intensity is correlated with price rigidity. Perhaps part of the weak correlation between concentration and price rigidity simply reflects the fact that both are related to capital intensity.

Among the second group of conditions, the cases where market control involves collusion have been frequently pointed out. Every revision of a price agreement opens the door to controversy and thus imperils the continuance of the agreement. Hence frequent revisions are avoided. Collusion is, however, probably not typical of situations of market control in the American economy today.

Mr. Blair deserves our thanks for reopening this important controversy, which has never been satisfactorily settled, and for suggesting promising new lines of research.

FRANK C. PIERSON: The paper presented by Mr. Poole, to which I will confine my attention, steers a middle course in an area where extreme positions were once the order of the day. He makes a three-way distinction between inflation in periods of deficit-financed military spending, in peacetime booms in the private sector, and in periods of creeping inflation independent of either peacetime or wartime boom spending, which I find both helpful and dangerous —helpful in avoiding the tendency to generalize too broadly from the special circumstances surrounding such severe inflations as 1946-48, but dangerous in suggesting that long-run inflation can be anything other than the net result of a series of short-run situations. Thus, any long-term inflationary bias which union wage policy may impart to the economy cannot be disassociated from the role which unions play in different phases of particular, presumably successive, cyclical periods.

The fact that, currently, the subject of union wage policy as a cause of

inflation may strike some as rather quaint, if not downright quixotic, is symptomatic of the rapidly changing world in which we live. Even the more optimistic projections foretell a further rise in unemployment in 1955 over 1954, despite an expected increase in real national product. Similarly, discussions of longer range prospects are giving increasing attention to the problem of structural unemployment, suggesting that long-term growth influences in the private sector may well not be strong enough to keep the economy close to its full employment potential. In this kind of environment, the question of union wage policy as a cause of inflation becomes something less than the burning issue of the hour.

Reference to the current position and longer term prospects of the economy underscores the importance of distinguishing between different types of full employment or high-employment situations in analyzing possible inflationary effects of union wage policies. If it is assumed that the economy, in a single leap as it were, suddenly achieves full employment, that labor and physical resources are literally fully utilized or even overstretched, and that supply inelasticities are much in evidence, analysis of the role played by unions leads to one set of answers. If, on the other hand, the economy is assumed to be moving rather gradually towards full employment and that severe labor and other resource scarcities are not developing, a quite different set of answers is obtained.

Economists—quite rightly, in my judgment—have given increasing attention to the possibility of inflation developing under conditions of less than full employment. The general rationale of this view is that wages and prices may rise rather quickly in conjunction with relatively small increases in aggregate demand and employment. (The 1933-37 period is sometimes cited as a case in point.) The converse of this proposition also deserves attention; namely, that despite the continuation of generally prosperous conditions, small increases in unemployment are quite likely to occur and when they do, they quickly lead to a slackening off, if not complete cessation, of inflationary influences. Speaking particularly of union wage policy, this is one of the main lessons to be derived from the last two recessions, 1948-49 and 1953-54. In both periods, wage increase pressures attributable to unions declined markedly and the increase in the general level of money wage rates, even allowing for gains in fringe benefits, was hardly more than the oft-cited 2 or 3 per cent average annual increase in physical output per man-hour.

The other side of the coin is the long-run effect on wages and prices which can be attributed to union policy during successive contraction periods. Since it seems clear that under collective bargaining wage rates are less likely to fall in periods of declining demand than under conditions of nonunionism and, therefore, that any rise in wage rates will start from a higher base than would otherwise obtain, the effect of union wage policy over the long run is to make prices generally higher than they would be in a world without trade-unions. Indeed, it is in periods of falling demand or of continuing general unemployment that union policy doubtless has its greatest effect on wage rates and prices. As already noted, in the 1948-49 and 1953-54 contractions, the level of money wage rates was not only maintained but was even increased some-

what. Isolated cuts occurred, but only as last-resort measures to cope with extreme situations. Lacking collective bargaining, there can be no doubt but what wage reductions, and hence price reductions, would have been more widespread in these two periods. If account were taken of all the other price-sustaining influences operating in periods of declining business activity, the possibility of any significant drop in the general level of wages and prices seems remote indeed.

For a variety of reasons which need not to be enumerated here, most economists would not recommend widespread wage cutting as a way of dealing with cyclical declines. I share this view and presumably Mr. Poole does too. But are we prepared to deal with the consequences of the alternative policy; namely, that wages and prices will follow an upward trend over time, rising in expansions considerably more than they fall in contractions? Mr. Poole notes that in both the 1948-49 and 1953-54 recessions the government was slow to resort to deficit financing as a way of dealing with the decline in business, suggesting that any inflationary pressures stemming from this quarter need not be taken too seriously. As a bit of contrary evidence, he might well have mentioned the fact that in the 1954 Congressional elections the Democrats were on the whole singularly successful in exploiting the small increase in unemployment which had occurred in the immediately preceding period. From the viewpoint of long-run relationships, however, the point deserving greatest emphasis is that the general level of wages and prices showed little tendency to decline in either of these two contractions. With wage and price cuts removed as a way of coping with business recessions, the long-term trend in the money-price level can hardly be anything else but up.

This makes Mr. Poole's analysis of union wage pressures in periods of expansion or high employment doubly important. If unions not only prevent money wage rates from falling in contractions but also push them up markedly in expansions, the long-term prospect for the value of the dollar would seem to be decidedly dark. Again, Mr. Poole is inclined to take an optimistic view, arguing there is no convincing evidence that unions exert an independent influence on wage rates in expansions and that a rise in wage rates need not necessarily mean a corresponding rise in the total quantity and/or velocity of money. Those who take issue with these two propositions have to go pretty far afield, citing political or other indirect influences exerted by unions of an equally vague or tenuous nature to buttress their argument. Compared to such factors as heavy replacement needs, large accumulations of liquid assets, bursts of investment spending, consumer buying on credit, and the like, union wage policy can hardly be more than a minor element in peacetime inflations. This being so, proposals designed to hamstring unions on the grounds they are a major influence making for inflation in expansions would seem to fall far short of the mark.

The foregoing suggests that the only significant long-run inflationary influence that can be properly attributed to unions results from their efforts to hold up wage rates in periods of decline or depression. The inflationary effects of union wage policies in periods of expansion appear to be relatively minor and it is in these periods, of course, that inflationary pressures are most active and

of greatest consequence. This is not to argue that unions can or should escape the effects of measures taken to ward off or control inflationary developments in periods of cyclical or longer term expansion. On the contrary, if a vigorous counterinflation program is undertaken by the monetary and fiscal authorities, the unions are likely to be among the first groups to feel its repercussions in terms of increasing job insecurity, employer resistances, and antistrike sentiment among the membership. Nor would many argue that the unions should be immune from the consequences of policies required to preserve general economic stability, especially since the unions' continued existence as free institutions clearly depends on the successful execution of such policies. What is important is to keep inflation control measures on as broad and impersonal a basis as possible, with all groups carrying their share of the burden and no one group benefiting from the weaknesses or difficulties of any other. A program to check inflation by singling out a particular group for punitive action is hard enough to defend in terms of social equities, but it is even more questionable in terms of effective economic policy.

PRICING IN TRANSPORTATION AND PUBLIC UTILITIES

SOME IMPLICATIONS OF MARGINAL COST PRICING FOR PUBLIC UTILITIES

By WILLIAM VICKREY
Columbia University

As a preface to a discussion of the role of marginal cost pricing, it is perhaps well to state explicitly that in common with any other theoretical principle, the principle of marginal cost pricing is not in practice to be followed absolutely and at all events, but is a principle that is to be followed insofar as this is compatible with other desirable objectives, and from which deviations of greater or lesser magnitude are to be desired when conflicting objectives are considered. On the other hand, I propose to maintain that marginal cost must play a major and even a dominant role in the elaboration of any scheme of rates or prices that seriously pretends to have as a major motive the efficient utilization of available resources and facilities.

Some of the conflicting considerations may be mentioned briefly. On a mere mechanical level, there is always the cost involved in the determination, publication, and administration of a rate structure. The relative importance of this consideration obviously declines as the value of the unit of sale becomes larger, so that, for example, one could expect that more refinement would be justifiable in the case of overseas airline fares than for short-haul train trips. Ability of the consumer to respond intelligently is also a limiting factor of a somewhat similar force. Thus a service used frequently by the same individual, such as local transit, will bear relatively more complexity than a service used rarely, such as parcel checking. And services used primarily by business firms, whose choices among alternatives are in the hands of relatively expert specialists, will also bear more complexity. Thus freight tariffs can stand being fairly complex, though this is by no means a justification of the present jumble.

Another consideration that may in some cases operate to require modification of pricing policies based on marginal cost is the desirability, other things being equal, of minimizing inequalities in income. In an ideal world where there existed an ideal income tax capable of producing any desired distribution of income without administrative expense or deleterious effects on incentives, it would be possible to leave

to this measure all redistributions of income, and determine rates on the basis of securing the best possible allocation of resources. In practice, however, such measures of redistribution always have, at the margin, some deleterious effects, so that if modifications of the pricing scheme can be shown to have significant effects on the distribution of income, it will in general be desirable to depart at least to some extent from the strict marginal cost price system. For provided that the departure is small enough, it will in general be possible to provide for some improvement in the distribution of income with a cost in terms of impairment of incentives and misallocation of resources that is less than if the same improvement had been achieved through additional direct redistributive measures, such as increased income taxation. In many cases, however, the relation of the pricing structure of a particular utility service to the distribution of income will be slight or uncertain; in which case the distributional considerations will be correspondingly irrelevant. It is indeed likely that in most cases the magnitude of the modification that would be appropriate on this basis would be small. A major exception may be in the pricing of local transit services, where the incidence of a fare increase, regarded as a tax, is far more regressive than any substantial revenue for which it might be considered a substitute. This consideration would argue for pushing transit fares below the level that would otherwise be appropriate and even, possibly, below marginal cost.

Another point at which prices based on marginal cost may require modification in practice is where such prices come into too violent conflict with popular notions of equity. For example, it is clear that on marginal cost principles, transit fares should be substantially higher during rush hours than during off-peak hours. Yet a proposal of this sort is likely to be considered inequitable by many if not most of the lay population on such grounds as that rush hour riding is less comfortable, is more of a necessity, is more heavily concentrated among low-income groups or at least among working people; or is, according to some naïve method of cost allocation (as by first computing a cost per vehicle-mile and then dividing this by the average load at various times), less costly. Some of these notions of equity may be considered to be valid in their own right, as the above consideration for the relative income level of the rush hour riders would be if the facts as to the income distribution of riders actually bore out the assumption. Other notions of equity may be so strongly held as to require, as a matter of practical politics, some consideration in the design of rate structures if the proposals are to succeed. But while the economist may have a role to play in the design of such compromise measures, these compromises should in most cases be regarded as inferior solutions to be

superseded by better ones as soon as public opinion can be educated to a more rational view.

Other considerations of a general nature, such as the desirability of promoting decentralization, health, intersectional and international enlightenment, and so on, may have a bearing on the selection of rate structures. But the modifications that might be justifiable on such grounds are in many cases minor and of an uncertain general direction, and as very little of the opposition to marginal cost pricing stems from such considerations, I will leave them with this brief acknowledgment.

By far the most important of the considerations that conflict with the strict application of marginal cost pricing is the need for revenues. Many of the more extreme advocates of marginal cost pricing for decreasing-cost industries seem tacitly to assume that the government has some perfectly costless and neutral source of revenue that is capable of very substantial expansion without ill effects. Such a state might be approached, for example, if we had an income tax free of its multiple defects, evasion proof, with no marginal costs of administration or compliance, and including in its base not only money income but all forms of direct income in kind, including an imputed value for leisure. Needless to say, this is far from the case. A convenient way to express the degree of departure from the ideal, for present purposes, is to estimate a marginal cost of public funds, which will be a percentage indicating the added administrative costs, compliance costs, and indirect losses through the misallocation of resources and the distortion of incentives that will result from increasing the level of public receipts. Such a cost will of course vary from one governmental unit to another. Purely as an offhand indication of the orders of magnitude involved, one may hazard the guess that in small units with a good community spirit or in large units operating with a good civil service and efficient administration, under favorable conditions and with low over-all tax levels, it is conceivable that the marginal cost of public funds might get below 10 per cent, while under unfavorable circumstances, say in a corruptly administered medium-to-large city, excessively circumscribed in its taxing powers, the figure might well exceed 50 per cent.

Obviously, it will not pay, on any concept of the public welfare, to carry a marginal cost pricing policy all the way to the limit, so that the last dollar of subsidy barely yields a dollar's worth of benefits to the using public, when the securing of this dollar for the subsidy imposes burdens of more than a dollar. In the simple case where all demands are perfectly independent, the indicated solution is to have all prices exceed marginal cost by a percentage equal to the marginal cost of public funds divided by the elasticity of the demand controlled

by each particular price. Another way of arriving at substantially the same result is to consider prices made up of a base price at marginal cost plus an excise tax. Such excises on public utility rates would receive special consideration as possibly involving lower administrative costs, in the case where their imposition would take the form of the removal of a subsidy that might otherwise be indicated, or where administrative costs would be reduced by reason of the public ownership of the utility. But other than this there would be no justification for higher excise taxes on utility services than on other goods and services.

There is, however, very little to be said for the shibboleth that the rates should be above marginal cost by an amount just sufficient to produce revenues just covering average cost, however this may be defined. To be sure, there are often political and administrative advantages to having operations of a public utility carried on by independent agencies, whether private or public, rather than as governmental departments on a par with other nonrevenue producing agencies of government. It is often argued that this can only be done if the agencies are financially self-supporting. But to me this would be taking a far too defeatist attitude towards our ability to develop appropriate political institutions. Surely the fact that excise taxes are levied on a number of particular products, such as automobiles, gasoline, photographic equipment, and the like, will not be held to have seriously impaired the independence and efficiency of management of these industries, nor, conversely, if for good and sufficient reasons the taxes should be replaced by corresponding subsidies, would one expect the performance to be notably worse. To be sure, abuses occur in the distribution of subsidies, but except where the basis of the subsidy is ill-conceived, these abuses are but the obverse of tax evasion that occurs with excise taxes.

Similarly, if an independent public authority, instead of being required merely to meet its own expenses, is in addition required to turn over to the appropriate governmental unit a stipulated percentage of its gross receipts, either as an explicit excise tax or as an "in lieu" payment, I do not think anyone would imagine that this in and of itself would operate to impair the efficiency and independence of the agency, provided only that the amount is computed in a suitable manner and that the rates and methods of computation are fixed on a reasonably permanent basis. There seems to be no inherent reason why a subsidy cannot be handled in the same manner. There would, to be sure, be a somewhat greater temptation to attach conditions to the subsidy and thus open the door to interference with the independence of the management, and individuals may differ as to the extent to which and the occasions on which this would be desirable. But there is no necessity for this, and if independence is indeed considered a sufficiently impor-

tant objective, there should be no great difficulty in specifying the manner of payment of the subsidy in such a way as to slam the door on such political interference. There need be no greater political bickering over the level of such a subsidy than over the rate of an excise tax.

This is not to say, however, that there are no impediments to the pursuit of a thoroughgoing marginal cost pricing policy by independent agencies. In particular, attempts to adjust prices to variations in marginal cost produced by the installation of large units of capacity or by unforeseen scarcity or surplus may, in the case of a public agency, produce financial difficulties of a sort that may well give rise to demands for revision of the subsidy provisions that would be too strong to resist. Even so, if this breakdown of independence could be resisted and the substantial fluctuations in earnings weathered by appropriate financial measures such as borrowing or the accumulation of reserves, such fluctuations would yield better resource utilization than a policy of keeping earnings as even as possible from year to year.

In the case of a regulated private utility, the incentives that would result from such a short-run marginal cost pricing policy for delaying expansion so as to raise marginal costs and with them the rates that would be warranted and consequently profits, would produce additional difficulties. If to prevent this the regulatory agency is empowered to dictate the installation of capacity, little discretion indeed would be left to private management, even if regulation could be kept from breaking down under the added administrative burden. Thus whether the agency be public or private, it does appear that it would be difficult to preserve political independence and still provide for the variations of rates in accordance with short-run excess or deficiency of capacity.

But whatever the conclusion as to the desirability of actual payment of subsidies, there can be little question that to require utility users to bear tax burdens in addition to paying the entire average costs is undesirable. The situation is bad enough when utilities must pay income taxes, property taxes, and other general taxes on the same basis as other industries. To impose in addition special discriminatory taxes and excises is completely unjustifiable under any but war emergency conditions. A first step in the direction of marginal cost pricing would be the removal of all such discriminatory tax burdens, such as the federal excises on transportation and telephone service. A second step would be the exemption of public utilities from the payment of such general taxes as can readily be abated without creating difficult administrative problems. This would include all in-lieu taxes, as well as property taxes on property improvements and movables specifically designed and used for utility service, and possibly taxes on land as well, though where property such as land is convertible to other uses,

its exemption when normally devoted to utility uses might give rise to incentives for artificially extending the utility operation to cover an unnecessarily large area of land for the sake of extending the scope of such an exemption. Exemption from income taxes raises rather troublesome issues of allocation and accounting where utility companies carry on nonutility activities or otherwise compete directly in subsidiary operations with nonutility companies. But in general there is room for a very substantial step in the direction of marginal cost pricing through tax adjustments without getting involved in outright subsidy. Of course, such a program need not be carried out all the way to the limits suggested by the above considerations if for other reasons it is found desirable to keep prices further above marginal cost than this would make possible. Moreover, this argument would not preclude special taxation of utilities exploiting a scarce natural resource such as water power or natural gas, as a means of retaining for public use the pure economic rent arising in such situations.

Another argument that is often made for avoiding subsidies is that only by requiring customers in the aggregate to pay the full cost of the service can it be made absolutely certain that the service was worth providing. To do this, however, would be somewhat analogous to a playgoer who always rushes home before the end of the last act in order to see whether the TV show that he missed by going to the theater seemed better or worse than the play. Destructive testing is occasionally necessary, but to adopt a policy of applying an injurious test in every case is surely wasteful. Even if only those services are provided that could, it is estimated, pay for themselves, it will ordinarily be far better to operate such services at marginal cost. Even so, policy would err on the conservative side and many worth-while services would fail to be provided because they could not be made to pay for themselves in this way. There is no point in aiming at the wrong target merely because it is easier to tell if you hit it. Moreover, in practice, decisions as to whether to provide a service must be made fairly far in advance with a more or less permanent commitment of capital involved; so that, in practice, whether a service can be made to pay for itself must be estimated in advance and these estimates are almost as uncertain as estimates of whether the service is worth while on an over-all basis. Even if a service cannot pay for itself, this is no indication that it is not worth while. If a mistake is made in such forecasting, marginal cost pricing at least minimizes the resulting waste and salvages what can be retrieved, while an attempt to recover the full costs as nearly as may be often compounds the original error by allowing excess capacity provided in error to remain unused.

Another important consideration to be kept in mind is that marginal

cost pricing will not be adopted everywhere simultaneously, and where closely competing services continue to be rendered at rates substantially above marginal cost, reduction of the rates under consideration to marginal cost might well produce a poorer allocation of resources than somewhat higher rates. Indeed, if the only consideration were the allocation of a given demand between two closely competitive forms of service, the proper price for the service under consideration would be one that makes the differential between the prices of the two services reflect the differential in marginal cost, at least where the application of this principle leads to a unique result. It should be noted that it is an equal absolute differential and not an equal percentage relationship that is sought. This may cause difficulty where the units are not directly comparable, especially where different consumers would have different substitution ratios and discrimination between them is not feasible. For example, if air express rates are to be set so as to preserve the proper cost differential over established surface handling charges, some allowance should properly be made for the lighter packaging that would often be practiced for air shipment, and this allowance might vary considerably from customer to customer.

There may also be several competing services, differing in the degree to which their rates exceed marginal cost. In which case some sort of compromise will be necessary, with the influence of each competing service weighted according to the appropriate cross-elasticity of demand. For example, if rates for water transportation are to be set, it may not be possible to do this in such a way as to cause the rate differentials to agree with the marginal cost differentials for both rail and truck shipments, if the rates for these latter are not to be disturbed. Of course, where a single agency, such as the ICC, has control over the rates of all of the competing services, all of the rates can be adjusted together to a common margin above marginal costs and there is no difficulty in preserving the competitive relationships among the various services whatever the general level of rates decided upon, except possibly where it is necessary to distort the relationship in order to give the agency providing each service a fair return and no more on its investment. In such a case the problem might better be met by the imposition of appropriate discriminatory taxation on one or more of the operating agencies so as to bring their rates into an economical relationship with the highest rather than to permit traffic to be uneconomically diverted because of differing relationships between the marginal and average cost of the several competing services.

Of course, in a general sense every service competes with all other commodities and services for purchasing power and for the use of resources, and it is sometimes claimed that, since imperfect and monopo-

listic competition prevail fairly widely in the private sector of the economy, producing prices considerably above marginal cost on the average, therefore public utility prices should likewise be above marginal cost by a like percentage. This argument must be used with caution, however. At most, the presence in the economy of a substantial sector that appears to be genuinely competitive in the relevant sense would bring the average discrepancy between marginal cost and price down to a more moderate figure than would be thought of if attention is focused primarily on the imperfectly competitive sectors. Moreover, in applying such an argument it must not be forgotten that self-produced commodities and services, not produced through the market, also compete in this way. Such nonmarket production, including the utilization of leisure time, constitutes a very large area where there is no market friction, monopoly behavior, or taxation to drive a wedge between the marginal cost and the marginal value to the individual. Services that compete with such self-produced products would need to be priced particularly close to marginal cost if the best attainable allocation of resources is to be reached.

On the other hand, complementarity relations must be considered, also. It might be desirable to price at less than marginal cost a service that happens to be strongly complementary with services that have established prices unusually far above marginal cost. A somewhat inadvertent example of this is the practice of allowing the use of feeder highways at charges often substantially less than marginal cost, balanced in some instances by the charging of tolls substantially in excess of marginal cost on bridges, tunnels, and the like. Conversely, services that are strongly complementary with leisure or nonmarket production might warrantably be priced further above marginal cost than otherwise. This proposition might be held to indicate higher rates for recreational travel, amusements, and the like, except for the fact that there are also strong substitution relationships to be taken into consideration as well and that accordingly the demand for such services is often highly elastic.

The taking into consideration of complementarity and substitution relationships in the application of marginal cost pricing is thus an extremely complex matter that cannot be reduced to any simple rule of thumb. Except for a few special situations, however, it does not seem that complementarity relationships would in themselves require any but relatively minor modifications of marginal cost pricing practices.

But whatever arguments may be advanced for departing in various degrees from a strict marginal cost pricing policy, no sound pricing policy can be developed without using marginal cost as one of the prin-

cipal determinants. Indeed, while marginal cost pricing has been discussed most frequently in a context of decreasing cost situations and subsidies, marginal cost has an important role to play even where economies of scale are absent and there is no problem of self-liquidating versus subsidized operation. Adequate consideration of marginal cost in the setting up of a price structure often leads to structures quite different from those in general use, wholly aside from the question of the proper general level of rates. Even where economies of scale are substantial, marginal cost considerations may be much more important in relation to the structure of rates than to the level.

To illustrate the structural importance of marginal cost pricing, let us consider the following example. A daily train is to be operated from A to B, and possibly to continue on to C, and return. Constant returns to scale prevail over the range of operations contemplated and costs are of three kinds: 20 cents per seat per day for capital and similar charges on the equipment, independent of the distance operated; 30 cents per seat for operating expenses for each leg of the trip; 10 cents per passenger for each leg of the trip for wear and tear on the equipment, cleaning, and service to passengers. It is assumed that equipment can be found to make the train up to any desired number of seats at strictly proportional costs but that it is impractical to change the consist of the train at B and that if it is to run through to C at all, the entire train must be run. Demand for the AB leg is linear, ranging from 2,000 at a price of zero to a maximum price of $2.00 that the most eager passenger is willing to pay; demand for the BC stretch is one-fourth as great, ranging up to 500 passengers at a zero price, with the same maximum price.

Some simple calculations will show that if the train is operated between A and B only, with the capacity exactly adjusted to the traffic, average and marginal costs are 50 cents per trip, and that at this fare there will be 1,500 riders each way, yielding a total consumer's surplus of $2,250.00 per day for the round trip. On the other hand, if the train is operated through to C, marginal cost for the BC portion of the trip is only 10 cents, since there will inevitably be empty seats, while the marginal cost for the AB trip will be 80 cents, the cost of providing additional seats for this trip having risen because the additional seats, if provided, will now have to be carried all the way to C. At fares equal to these marginal costs, there will be 475 BC passengers, whose consumer's surplus for the round trip will be $902.50, and 1,200 AB passengers, with consumer's surplus amounting to $1,440.00, or a total of $2,342.50. As this is a case of constant returns to scale, we can expect that revenues at marginal cost rates will just meet costs, and this is indeed the case. The net welfare product is thus in each case

the consumer's surplus generated, and accordingly the second mode of operation is to be preferred to the first, and this is, indeed, the optimum mode of operation.

Now in principle, in a case where there are constant returns to scale, it should be possible to allocate costs in such a way as to produce allocated costs identical with marginal cost. And yet I venture to suggest that in a case such as the above the optimum result shown would not be reached by any of the usual cost allocation procedures unaided by marginal cost concepts. The concept of marginal cost cannot be dispensed with as a tool for making cost allocations even in the constant returns to scale case.

To be sure, the above example is a little unusual in that although it is not strictly speaking a case of increasing returns, it is a case where indivisibilities enter through the assumption that it would not be possible to provide the service in two or more trains, with only some of the trains operating through to C. Thus the rather unusual result arrived at would not occur in a case where the production process is perfectly divisible and where accordingly competition is possible. But such cases do occur in varying degrees of complexity embedded in a context of decreasing costs. Yet in many cases the more dramatic results of the application of marginal cost pricing will not be a reflection of the degree of decreasing cost, but rather of the pattern of cost interrelationships produced by the indivisibilities.

Indeed, if the only implication of marginal cost pricing were that in decreasing-cost industries the price structure should be reduced more or less uniformly by a percentage reflecting the amount by which the elasticity of the long-run production function falls short of unity, one might be justified, in many cases, in feeling only a very restrained enthusiasm. For example, studies I have made of the marginal costs for railroad freight service indicate a level in the neighborhood of 80 per cent of average costs, on a long-run basis. Subsidies of the order of 2 billion dollars a year, which would be indicated in order to enable rates to be cut to a marginal cost level, would produce a net gain in national product of some 250 billions, assuming an elasticity of demand of about unity. In view of what has been said above concerning the marginal costs of public revenues, this would seem to have relatively little to promise. Actually, in such a case one could probably rest content with recommending that taxes bearing on freight transportation in one way or another be abated as far as administratively possible.

Passenger service is a somewhat different matter, however. While if we measure output of passenger service in terms of passenger car miles it is possible to arrive at a figure somewhat comparable to that for freight service, this is not the end of the story. The degree to which this

service is actually utilized is positively correlated, to a considerable degree, with the density of traffic: a 10 per cent increase in traffic generally requires an increase of considerably less than 10 per cent in the space that must be provided to give an equivalent quality of service. Moreover, as traffic density increases, the quality of the service tends to increase, in terms of frequency, variety, speed, and sometimes in quality of equipment. Or to put it another way, the fact that passengers will not wait as readily as will freight for the accumulation of trainloads of minimum cost size means that trainloads are generally smaller than would produce a minimum average cost per passenger and thus there are substantial economies of scale from increasing the number of passengers per train to be compounded with the economies of having more trains per year per route. All of this is rather difficult to evaluate, but it seems not impossible to place the marginal cost of passenger service as low as one-third of the average cost, particularly on lines where the density of traffic is fairly low and the average haul short. Some support for the more extreme point of view may be found in Gilbert Walker's figures comparing main line with local and branch line passenger service costs in England, given in an article in the *Oxford Economic Papers* for March, 1953.

It is fashionable in railroad circles to bemoan the present deficit shown for passenger operations as constituting one more unfair burden thrown upon railroad freight traffic, placing it at an improper disadvantage as compared with truck traffic. But if it is true that the elasticity of costs for passenger service is substantially lower than for freight, this would justify a substantial discrimination in favor of passenger service. The existing relation between passenger and freight rates may thus be more desirable, on the whole, than one where passenger service is required to meet all of the costs for which it is incrementally responsible as a whole, to say nothing of a share in the costs that are inextricably joint as between passenger and freight service. Of course, an even better allocation of resources could be obtained if railroad passenger services could be subsidized from general tax funds rather than, in effect, from a special tax on railroad freight service.

In another area, it is often claimed that telephone service is rendered under conditions of increasing rather than decreasing costs. It is claimed, with some justice, that the central office equipment required to furnish interconnections between subscribers increases more rapidly than in proportion to the number of subscribers. Comparisons of costs between large and small communities also seem to indicate increasing costs. But this is not the whole story. Much of the outside plant of telephone companies can be installed, under given outside conditions,

at much lower unit costs at high densities of service than at low; long distance service in particular seems to have a strong decreasing cost characteristic. The economies of scale in the outside plant would seem to be sufficient in most cases to much more than offset the diseconomies of scale in the switching plant. Nor is the urban-rural or large town-small town comparison quite appropriate. While it is true that a large exchange will usually find that the conditions under which the outside plant must be installed are more costly than a small exchange, this is not caused by the size of the exchange but is only an associated condition. Actually, if in some given city such as Detroit, for example, one were to imagine that nine-tenths of the customers taken at random had never installed a telephone, I would be very much surprised if it would have been possible to design and construct a telephone system to serve the remaining tenth of the subscribers at as low a cost per subscriber as is obtainable with the existing pattern of service, particularly if the amount of use per telephone were to be held approximately the same. Moreover, even were it true that costs under given circumstances tended to go up more than in proportion to the number of subscribers, this might be considered offset by the increased value of the service rendered when a subscriber can reach a larger number of other phones in the community. Thus telephone service is by no means to be excluded from the candidates for subsidy if marginal cost pricing is adopted as a general principle.

One of the major characteristics of marginal cost structures is the rather marked variation in such costs as between-peak and off-peak demands, whether the peak be in terms of daily, weekly, or seasonal fluctuations, or even as between congested and uncongested sections of route. In the ideally simple case, where demand is exactly predictable and capacity is a sharp and rigid limit, the appropriate marginal cost price is one which covers only the utilization or service costs as long as demand at that price is below capacity, and which is at other times or places just sufficient to keep effective demand at the capacity level, capacity being in turn adjusted so that the amounts obtained over and above the service costs during such periods of capacity use are just enough to cover the marginal costs associated with an increase in capacity. The marginal cost of a peak period unit may be thought of as the opportunity cost involved in depriving the next most eager consumer of the service, or of a cost arrived at by taking the marginal cost of an increment of capacity and deducting as a credit the excess of the value of all other units of service which the increment of capacity makes it worth while to produce and sell over their respective direct variable costs.

The picture is of course often complicated by the fact that various

different capacity limits often operate on the same service at different times and in different ways. In the very short run, for example, the number of seats scheduled to be operated on a given train may be fixed; with some advance notice, cars can be added or dropped, but perhaps only by shifting equipment from some other service; over a longer period, schedules can be adjusted and eventually adjustments to track layout can take place. The appropriate measure of the peak also varies: where the timing is crucial, as with transit service, limitations imposed by track or roadway capacity operate on the basis of a volume measured over an interval of say five or ten minutes; with respect to the availability of equipment, the peak is determined by integrating over a period equal to the time taken for a round trip, say ninety minutes.

Capacity limits on output of nonstorable services often operate to produce rather drastic fluctuations in marginal costs that are regular and predictable enough to be used as the basis for rate making. For subway service in New York, for example, it has been estimated that the marginal cost of a fairly long rush-hour trip would be on the order of 30 to 50 cents, while a comparable nonrush-hour trip would have a marginal cost of only 8 to 10 cents, and rush-hour trips in a direction opposed to the major flow of traffic would in most cases be a surplus by-product service with a marginal cost substantially zero. Costs per passenger mile will vary equally drastically for different portions of a single trip on a single train. An evening rush-hour trip from Coney Island to Bedford Park in the Bronx would have a zero marginal cost for the Brooklyn portion of the trip, a cost rising to about 5 cents per mile for the upper Manhattan portion of the trip and falling off to 1 or 2 cents per mile for the Bronx portion of the trip.

Capacity limits are, however, not always rigid. The usual way of expressing a somewhat elastic capacity limit is in terms of a more or less sharply rising marginal cost curve. In many cases, however, while the capacity limits on the volume of service offered are quite rigid, elasticity at the capacity limit is provided by impairment in the quality of the service offered. It may not be possible to run more trains or longer trains on a given route, at least in the short run, whether from lack of track capacity or of equipment; an increase in traffic will be accommodated by having a larger proportion of standees, or more intense crowding. Costs to the operating agency may be very little affected, and in this sense one might say that marginal cost is very low; the cost, however, is to be measured in terms of the deterioration in the value of the service to the former passengers. It is not often realized how great a marginal cost computed in this way can easily be. If the addition of 20 passengers to a car already containing 200 passengers creates increased crowding, that the original passengers would on the

average pay 3 cents each to avoid, this is a cost of $6.00 to be divided among the 20 passengers causing it, resulting in a marginal cost of 30 cents each. Or as demand approaches the theoretical capacity, the slack necessary to insure taking care of customers as they apply may vanish, with the result of longer and longer queues or delays in getting service. The queue or the delay may operate to cut down to some extent the demand for service, but in general this will be an inadequate deterrent without substantial increases in the rate as well, since the operative deterrent for the individual is the average delay, not the much greater increment in total delays that will be caused by the addition of one person to the demand: not only will the additional customer have to wait while he works his way to the head of the queue, but all customers after him will have their waits increased by the time required to service the added customer, until such time as either the queue is entirely worked off or some potential customer is discouraged by the increased length of the queue.

In an extreme case where the control of the queue may require diversion of resources from the providing of the service, as for example may occur in some situations in telephone service, overload may even reduce the amount of service that can actually be rendered below what it would have been had demand been more moderate. For example, repeated attempts of thwarted subscribers to place calls may absorb the time of operators or of certain types of common equipment in an automatic exchange such as registers, senders, markers, and the like. Considerable additional complexity of central office equipment is often necessary to prevent paralysis in such contingencies.

Fairly extreme results also tend to occur in poorly controlled situations such as curb parking. Very marked differences in the amount of time which a would-be parker will have to spend in finding a place to park, and also in the distance that he will have to walk to get to his ultimate destination, on the average, according to whether, out of say 1,000 parking spaces in a given area, 999 are, again on the average, occupied, or whether the average occupancy is only 995 or 990. Again, the deterrent to say the 990th parker is only the amount of time he will have to search, and he takes no account, ordinarily, of the added searching time that his occupancy of a space will impose on those who come after. Metering of curb parking space on marginal cost principles would thus require rather substantial fluctuations in the rate per hour as the degree of occupancy fluctuates in the neighborhood of 100 per cent.

In summary, then, marginal cost pricing must be regarded not as a mere proposal to lower rates generally below the average cost level but rather as an approach which implies a drastic rearrangement of the

patterns and structures of rates. Indeed, it is this restructuring of rates that is likely to be the greatest contribution of marginal cost pricing to the improvement of the over-all efficiency of our economy, while the further gains that might be obtainable from the reduction of rates from a self-sustaining level to a marginal cost level, once the pattern of rates has been made to conform as closely as possible to marginal cost, are likely to be relatively small. The issue is thus not primarily one of subsidized versus nonsubsidized operation, though this is still an important issue. The dominant issue is one of whether the pattern of rates should be based on tradition, inertia, and happenstance, or whether it is to be developed by a careful weighing of the relevant factors with a view to guiding consumers to make an efficient use of the facilities that are available.

Perhaps some indication of the outstanding absurdities that occur in present utility rate structures may be worth while in conclusion. For example, in New York a new vehicular tunnel was opened a few years ago from the Battery to Brooklyn. Since it is a new facility and undoubtedly much more easy and pleasant to use than the old East River bridges, it must, forsooth, be made to pay for itself by the imposition of tolls starting at 35 cents, the practical consequence of which is to encourage continued heavy use of the Manhattan bridge for all trips for which that route is shorter than the tunnel, with the result that the streets near the Manhattan end of the bridge are the scene of some of the worst traffic congestion in the city. Marginal cost considerations would call for the collection of a substantial toll on the old East River bridges, at least during hours of heavy congestion, and a smaller toll or none at all for the tunnel, even though this might mean that the users of the bridges might be "paying for" the tunnel.

In suburban railroad service, the lowest fares offered are almost invariably the weekly and monthly commutation tickets used predominantly by commuters who travel almost exclusively in the rush hour when marginal costs are highest; next highest are multiple-ride tickets used by family members, often at the rush hours, but somewhat less frequently so. Users of one-way or round-trip tickets, on the other hand, are more likely to be off-peak or even counter-rush riders with very low marginal cost. Nor can this pattern be defended on the basis of elasticity. The daily commuter rides from almost absolute necessity, in most cases, whereas the occasional trips of other family members are often dispensable trips; further, the use of the family car for such trips is much more often a strong competitor, since the car is then not needed at home, the schedules are less frequent and convenient than in the rush hour, and many persons may be riding together. To be sure, in the long run there is elasticity to the daily commuter traffic in that

the fares influence the decision to move to the suburbs, but even to the extent that this is a significant factor, it will be some weighted average of the commutation and multi-trip ticket that would be the relevant rate to be considered by the prospective suburbanite. Political pressures seem to be partly responsible for this state of affairs: regular commuters have both a sufficient stake and a sufficient appeal to the public sentiments to bring effective pressure to bear on regulatory bodies. Some roads have been of late making tentative progress towards putting in a reduced rate type of ticket good only during the nonrush hours, but the attempt in most cases seems to have been rather half hearted, as the rate offered is usually still higher than that available in the multi-trip family ticket. Marginal cost pricing here would go much further than this and just about reverse the entire pricing structure.

The same delusion often gets a foothold in the local transit field. Philadelphia, probably on the basis of political pleas, has recently adopted a plan for selling strips of ten tickets, good for one week only, which of course are used predominantly by the high-cost rush-hour riders.

The rapid obsolescence of that great American institution, the open-section Pullman car, is in many ways the work of an inefficient pricing policy, itself in large measure the product of inefficient working arrangements between the Pullman Company and the railroads. No serious attempt seems ever to have been made to vary rates so as to balance the demand for upper and lower berths, so that what was and could still be a device for furnishing a satisfactory low-cost service is fast being relegated to the scrap heap.

And so it goes. One may, for various good and sufficient reasons, hesitate to embrace marginal cost pricing in all of its ramifications as an absolute standard. But no approach to utility pricing can be considered truly rational which does not give an important and even a major weight to marginal cost considerations. And when adequate weight is given to such consideration, important changes in present pricing practices will be indicated in many areas.

APPLICATION OF MARKET PRICING FACTORS IN THE DIVISION OF TRAFFIC ACCORDING TO PRINCIPLES OF ECONOMY AND FITNESS

By FORD K. EDWARDS
National Coal Association

The basic issue here under consideration would appear to be whether the transportation pricing mechanism, as it now operates, gives recognition to the inherent advantages of each mode of transportation. Does the pricing mechanism guide the traffic to the agency most fit to do the job? The annual bill for services rendered the nation by its regulated carriers reporting to the Interstate Commerce Commission now runs to nearly 20 billion dollars, and to nearly double this if one includes all other for-hire transportation and private trucking. Could a redistribution of the traffic among the agencies of transportation, as effected by pricing, reduce this sum total cost to the economy?

It seems desirable to first look at the economic motivations, principles, and structure of transportation pricing; secondly, to sketch out some of the problems and experiences bearing on the division of the traffic according to fitness and economy; and, thirdly, to try to formulate some working principles for the recognition of inherent advantages in competitive situations.

Definition of Fitness and Economy. It may be said that the shipper who buys transportation services seeks to employ his funds most effectively. He seeks to minimize his total transportation costs; and by total costs is meant the combined total of the carrier's tariff charges and the shipper's own expenses incident to the receipt, delivery, packaging, etc., of the freight. Fitness and economy to him mean rates and services.

Taking the economy as a whole, however, fitness and economy are believed to be achieved when the nation's traffic is so distributed among the agencies of transportation that the aggregate costs for all transportation (including shipper supplementary expenses) are lower than they would be under any other basis of distribution. Taking the nation's transportation plant—rail, highway, water, etc.—substantially as we find it, this objective would be achieved when each shipment is transported by that agency whose long-term out-of-pocket costs to handle it, when combined with an evaluation of the shipper's costs and conveniences (packaging, loading, etc.) produce the lowest sum total expense. The long-term out-of-pocket or incremental costs here imply a period

sufficiently long for changes in traffic volume to have had their full effect on the carrier's operating practices and plant. When the traffic is handled by the carrier with the lowest incremental costs, the portion of the carrier revenues carried down to "contribution" and "net" is maximized and that consumed in the coverage of out-of-pocket costs is minimized, assuming identical rates.

But the shipper knows little or nothing about carrier out-of-pocket costs, and in any event would be guided not by such costs but by the tariff rates which he must pay, factors of service and convenience considered. However, where two agencies of transportation compete, each carrier's effort to find the rate most profitable to itself will normally bring about a set of rate relationships between agencies which will roughly reflect relative fitness and economy. The urge to maximize profits will normally cause the carrier having significantly lower out-of-pocket costs, and hence the greater flexibility in adjusting its charges, to drop its rates to a point where it can get a very large share, if not the preponderance, of the competitive traffic.

Carrier Motivations. Carrier motivation centers around the maximizing of net revenues. Maximizing profits means maximizing the contribution to burden earned from each kind of traffic or, indeed, from separate movements of a given kind of traffic where grounds exist for differentiating one haul from another on the same traffic.

The mental arithmetic the carrier's traffic man is presumed to go through in pricing out each of his "differentiated" transportation services is set out in Table 1. It is merely the application of the universal endeavor of all who sell to determine that level of the price which, volume considered, will be most profitable to themselves. It is explained most descriptively as maximizing the contribution (over out-of-pocket costs), or as the marginal revenue-marginal cost analysis (equating marginal revenues to marginal costs).

It is a matter of arithmetic that when price reductions made to induce new business reach a point where the increase in total revenues resulting from the last few units added does no more than equal the increase in expenses incurred thereby, one has reached the point of diminishing returns. At this point the contribution to overhead burden (be it high or low) is at its maximum as Table 1 illustrates. (See line 6, columns 5, 6, 7.)

This whole proposition was neatly summed up fifty years ago with the explanation that the traffic manager lowers rates whenever it will increase net earnings; i.e., as long as gross earnings continue to increase faster than operating expenses. (A. T. Hadley, *Railroad Transportation* [1900], page 261. The schedule of figures in Table 1 sums up the end product of all the rate-making elements encompassed in the all-inclusive but rather ambiguous terms "value-of-service" or "ability to

TABLE 1

SCHEDULE OF PROJECTED RATES, VOLUME, CONTRIBUTIONS TO BURDEN, MARGINAL REVENUES AND MARGINAL COSTS*

Line	Rates Per Carload	Projected Volume Carloads	Total Revenue 1×2	Total Out-of-Pocket Costs†	Contribution to Burden 3−4	Marginal Revenues per Carload‡	Marginal Cost per Carload§
	1	2	3	4	5	6	7
1	$50	0	$ 0	$ 0	$ 0	$—	$—
2	48	10	480	320	160	48	32

4	44	30	1,320	960	360	40	32
5	42	40	1,680	1,280	400	36	32
6	40	50	2,000	1,600	400	32	32
7	38	60	2,280	1,920	360	28	32
8	36	70	2,520	2,240	280	24	32
9	34	80	2,720	2,560	160	20	32
10	32	90	2,880	2,880	0	16	32

* For extended analysis of the marginal revenue concept see *Economic Analyses*, Kenneth E. Boulding, 1948, page 526. It is important to note the assumption in Table 1 that added business can only be generated by price reductions, and that because of an assumed inability to differentiate between markets, the rates on all traffic which would move at $48, $46, etc., per carload, must be reduced to maintain uniformity. At rates near $40 to $42 per car the "contribution" to overhead burden (and net) becomes maximized at the figure of $400 (column 5). At a rate of $40 per car, column 1, the marginal revenue of $32 has been equated to (equals) the marginal cost of $32, columns 6–7. At this level the traffic in question does not burden other traffic; indeed, at any rate other than $40–$42 the ability of the traffic to "contribute" would not have been fully exploited, and to that degree, an unnecessary burden would be cast on other business of the carrier. The difficult problem, of course, is the determination of the volume of traffic which one may reasonably expect to induce with any given rate adjustment Were it not for this factor, rate making could be reduced to a combination of cost finding and arithmetic. Obviously, a working knowledge of the variable or out-of pocket costs is necessary These latter are taken as those expenses which are found to vary directly and proportionately with volume at the level of the firm's output most pertinent to pricing for the future. This is basically a matter of cost behavior within the industry. As J. M Clark pointed out (*Economics of Overhead Costs*, 1923, page 223), one can estimate the effect of added increments of business by observing the behavior of costs for a group of firms whose volume of output has been fluctuating over a period of time, or by taking a single period of time, comparing the costs for firms with a wide range of output. The Cost Section of the Interstate Commerce Commission has made wide uses of both approaches (Statement 4–54).

† Computed at $32 per carload.

‡ The marginal revenue is the added total revenue derived from selling one more unit. Thus, divide each increase in revenues, column 3, by the corresponding increase in carloads, column 2.

§ The marginal cost is the added cost incurred in producing one more unit, $32. Thus, divide each increase in column 4 by the increase in column 2.

pay.") Referring to the Act, Table 1 represents an application of the rate making rule, Section 15(a); that is, a giving of consideration to the effect of the rates upon the movement of the traffic. This latter, a basic ingredient of all market pricing, is no doubt inherent in the concept of a just and reasonable rate under Section 1.

Equilibrium Position Toward Which Transportation Rate Structures Tend. The existing rate structure of each carrier or mode of transportation presumably has evolved after much trial and error, through the

so-called "contribution to burden" or "marginal revenue" analysis, as illustrated in Table 1. It is as though the carrier's traffic manager took each piece of traffic and, starting with out-of-pocket costs as a floor, added such margin, considering the responsiveness of the traffic to the rates charged, as would maximize the contribution. The influence of regulation has here been to place such rate ceiling on the traffic with an inelastic demand as is necessary to no more than make the carrier come out whole (including return); also to prevent exploitation of traffic "wedded" to one carrier or one mode of transportation and literally at the carrier's mercy. The end product is subject to "smoothing out" to avoid undue discrimination between competing shippers.

In short, a rate structure tends toward an equilibrium position under which the rates on each commodity having an elastic demand settle to that margin above out-of-pocket costs as will maximize that commodity's contribution toward the overhead burden and the net. (The fully distributed cost concept does not provide a norm for setting the specific level of a rate. Where fixed or joint costs are present, "full costs" represent a philosophically insoluble problem. If arbitrary statistical apportionments are made, they do not reflect shipper response to the rate set.) As the contribution of traffic with an elastic demand is thus brought to its maximum, the burden resting on the remaining traffic having a comparatively inelastic demand is lessened, thus permitting the rates on this traffic also to settle to a lower level than would otherwise be possible.

The rate structure is the end product, in principle, of an endless equating of marginal revenues to marginal costs in each differentiated transportation market. Each class of freight constitutes a separate market which may be further differentiated by areas, directions of movement, or even point-to-point, where the intensity of the demand (volume, intercarrier competition, etc.) differs. Piecemeal breakdowns of markets permit differential pricing; i.e., the fixing of prices to attract specific additional tonnage and net revenue without sacrificing needed revenue on traffic of the same general kind presently moving freely elsewhere. Different ratings on live dry cell batteries from dead batteries is a classic illustration.

As one might expect, the universal application of the principle of "maximizing the net" in a myriad of highly differentiated markets has created an enormous range in the relation of rates to the out-of-pocket costs. Of the 199 commodity classes of rail freight traffic for which the relation of revenues to out-of-pocket costs was available in a 1951 study made by the Interstate Commerce Commission staff, twenty classes moved at rates significantly below (over 10 per cent below) their long-term out-of-pocket costs, nineteen classes moved at or near

out-of-pocket costs (within a range 10 per cent below to 10 per cent above), fourty-four classes moved at rates ranging from 111 to 149 per cent of out-of-pocket, eighty classes at levels 150 to 200 per cent, and thirty-six classes at levels 200 to 300 per cent or higher of out-of-pocket.[1] Revenues on individual commodity classes ranged from 20 to 30 per cent below out-of-pocket to 600 per cent above. Rates on the same commodity might vary from out-of-pocket to near 200 per cent above out-of-pocket depending on the intensity of competition on individual point-to-point movements or different lengths of haul. Revenues averaged 150 per cent of out-of-pocket costs for all carload traffic combined.

Probably the most significant comparisons are those based on the dollar contribution which each class of freight makes toward the overhead burden, for it is this factor which the carrier seeks to maximize.

Some commodity classes produce tens or hundreds of millions of dollars of contribution toward overhead burden and the net (see Appendix). Other traffic creates millions or even hundreds of millions of out-of-pocket losses. The rail passenger-train service accounting deficits, now running to over 700 million dollars, result in out-of-pocket losses estimated at between 400 and 500 millions. The rail less-carload out-of-pocket losses were computed by the Commission's Cost Section at over 100 million dollars in 1952.

In the motor carrier field the range in the relation of rates to out-of-pocket costs is not so extreme, though very substantial variations are to be found. In a southern motor carrier study made by the Commission's Cost Section[2] the revenues on single line minimum shipments within the South ranged from some 70 per cent of out-of-pocket costs on short hauls to nearly 140 per cent on long hauls. They averaged 98 per cent on all single line minimum shipments. In the heavier weight brackets revenues on single line shipments ranged from nearly 100 per cent of out-of-pocket costs to 150 per cent and, in a few instances, to nearly 200 per cent of out-of-pocket costs. The average for all single line and interline shipments was 119 per cent. Similar wide ranges were found in an earlier study (1945) covering ninety-five motor carriers in Western

[1] Based on ICC Statement 7-53, December, 1953. In terms of net ton-miles, a little over 4 per cent of the carload freight traffic moved at charges significantly below (over 10 per cent below) out-of-pocket; 12 per cent of the ton-miles moved at rates within striking distance of long-term out-of-pocket costs (10 per cent plus or minus); 44 per cent at charges 111 to 149 per cent of out-of-pocket; 25 per cent moves at charges 150 to 200 per cent of out-of-pocket; 14 per cent moves at charges 200 to 300 per cent of out-of-pocket; and about 0.5 per cent moves at rates which are 300 per cent or more of out-of-pocket.

[2] Statement No. 2-53, April, 1953. Out-of-pocket motor carrier costs taken as 90 per cent of the following: operating expenses, rents, taxes, and a 5 per cent return on the depreciated investment.

Trunk Line Territory when the traffic was broken down by weight brackets, mileage blocks, individual commodities, and directions of movements. (Supplemental report of the Federal Manager of Motor Carriers Transportation System and Properties.)

The purport of the foregoing is that the marginal revenue concept can produce a very wide range in the relation of rates to costs. On traffic where large out-of-pocket losses are incurred other contributing forces are obviously present.

Incentive Pricing as an Inducement to Economy and Fitness. In approaching the question as to whether transportation pricing, as it now exists, fully exploits the inherent advantages of the various modes of transportation, some useful contrasts can here be drawn between the utilities and the transportation agencies. A major key to the mass markets in electric power and natural gas has no doubt been the wide-scale use of incentive pricing. Block rates, volume rates, and other forms of quantity discounts are widely resorted to. One recalls the forecast of a utility executive that electricity would some day become so cheap that users would not exert the effort to turn their lights off. Perhaps this is far-fetched, but it no doubt represents the spirit underlying the electric power industry's approach to the marketing of its services, and natural gas is not far behind.

The basic motivation in utility pricing is to obtain the fullest possible utilization of existing plant and distribution facilities and, even more important, the far-reaching benefits of an increasing scale of output with its corresponding reduction in unit costs. Such pricing programs rest on a full and complete exploitation of the marginal revenue principle. Utilities not only differentiate between residential, commercial, and small and large industrial consumers, but each customer's consumption is so differentiated (by steps or blocks) as to encourage his maximum utilization of the company's plant and facilities. Even the small household consumer gets lower rates as his use increases.

In the illustration of the application of the marginal revenue concept in transportation (Table 1), the scope of the rate reductions was limited by the fact that any discount given to attract volume consumption was applied "across the board" to all the traffic. This method of attracting volume business is inevitably accompanied by an increasing "erosion" of net revenues on the business already at hand. The end effect in the illustration given was that it became unprofitable to charge less than $40 to $42 per carload even though it would be in the carrier's interest to take on added pieces of business at rates as low as $34 per carload. This would still exceed the out-of-pocket costs of $32 per carload. Referring to Table 1, column 3, the total revenues at $34 per carload totaled $2,720, the out-of-pocket costs $2,560, and the contribu-

tion to burden only $160. Under block pricing, the first ten carloads would continue to pay $48, the next ten $46, etc. The total revenues, if carried through to line 9, would have been $3,280, and the contribution $720. This is $320 more than the $400 economically attainable under a flat unit price of $42 per car.

Generally speaking, the rate problem appears to be one of so differentiating between markets, or users of the service, as not to unjustly injure one shipper in relation to another shipper in a common market. Where the business operations of each are dissimilar or the large shipper is in a position to exercise the advantages of bigness in any event, a failure to differentiate the markets may accomplish little purpose. Rather, it may operate to limit fitness and economy and the full exploitation of the carrier's capacity for mass output with its attendant possibilities for a reduction in unit costs and charges to all users of the service.

The application of block pricing principles in the transportation field is evidenced by the existence of less-carload or less-truckload rates versus carload or truckload rates; also by the application of LTL breakdowns of, say, 0-2,000 pounds, 2,000-6,000 pounds, etc. Beyond the carload or truckload rate level carrier efforts to apply the principle of incremental pricing have taken several forms. In the rail field they include heavier carload minimums, incentive rates which provide a lower charge per 100 pounds on that portion of the carload loading in excess of a given minimum loading, multiple-car rates, trainload rates, differentiation in the commodity itself (fine coal versus other coal), and special commodity point-to-point rates. Fourth Section relief is part and parcel of this market differentiation.

The shipper is under the same pressure to minimize his transportation costs as the carrier is to maximize his net. From his standpoint, the next lower "rate block" beyond the published carload or truckload rates may mean not only the foregoing rate possibilities but a turning to pipelines, conveyor belts, barge transportation, plant relocation, or the operation of the shipper's own highway or water operations. All factors considered, it is believed that in the transportation sector of the economy research has lagged in the application and use of incentive pricing as a means of realizing on inherent advantages.

A Case History—New Automobiles in Interstate Commerce. The recognition of inherent advantages among competing modes of transportation and whether such recognition could be obtained short of the exercise of the minimum rate-making power, were matters in issue before the Interstate Commerce Commission in Docket 28190, New Automobiles in Interstate Commerce. (259 ICC 475. The Commission report follows verbatim as to facts and discussion, the proposed re-

port of Examiner William A. Disque.) The Commission had launched a general investigation into the rates, charges, and practices in the interstate haulage of new automobiles by rail, by highway, and also by water when in conjunction with rail or highway. The rails had made sweeping and drastic rate reductions, particularly from assembly points for relatively short hauls, to overcome a heavy diversion of the traffic to other carriers. Whereas in the early thirties new automobiles had moved at first class, competition had brought the charges down to levels ranging from 30 to 100 per cent of first class, depending upon the severity of truck competition. Such of the rail rates as were below first class were frequently arrived at by deducting from motor charges certain amounts, generally some eight cents, estimated to offset the rail service disabilities.

The record developed that the shipper's routing was governed by the carrier's rates or charges, the shipper's own costs and conveniences (as related to each form of transportation), and even by subjective factors. Aside from rates, the items listed affecting mode of transportation included expedition, overnight delivery, nighttime deliveries, ready availability of service, regularity, dependability, flexibility, low-cost terminal storage, cleanness of automobiles on delivery, promptness in paying claims, and the cost of local haulage and unloading attached to rail movements. The rails sought to be left free to meet their competition and to publish rates necessary to obtain their "share of the traffic." They contended that they had spent millions of dollars in terminals, equipment, and other facilities to develop the traffic and intended to do their utmost to attract and retain all of it they could handle, at compensatory rates no further below a reasonable maximum level than necessary. They held that the Commission's staff cost studies demonstrated that their rates were generally between the out-of-pocket and fully distributed cost levels and could not, therefore, be condemned as noncompensatory (259 ICC 475, 533).

The motor carriers contended that inherent advantages in respect of service should be held paramount to other factors and should not be offset by other carriers through lowered rates. The motor common carriers argued that the time had arrived when the Commission should exercise its minimum rate-making power to save the revenues of all forms of transportation from further depletion; also to prevent the extinction of the motor common carriers. (*Ibid.*, page 530.)

As to contract highway carriers, the Commission noted that General Motors had helped develop seven contract motor carriers which hauled exclusively for it, that each of these seven carriers made its rates based on the transportation conditions under which it operated and without regard to the rates of other carriers (*ibid.*, pages 490-491),

and that these carriers co-operated closely with General Motors almost as if they were departments of its distributing organization. The contract carriers were assured a definite minimum volume of traffic so long as their rates were satisfactory to General Motors, a factor giving them a definite advantage over common carriers whose business was uncertain. These contract carriers felt that their real competition was with General Motors which was capable of setting up a highway transportation organization as a department of its own company.

The Commission found that under the interplay of competitive forces there had gradually evolved a distribution of the automobile traffic among the various modes of transportation which seemed to reflect the inherent service advantages of each agency more than it did the rates for the service. The water carriers held practically all the traffic from Detroit to Cleveland and Buffalo because they provided specialized mass transportation as well as good service at the lowest available rates.

The rails carried the major portion of the long-haul traffic because they provided the best mass transportation readily available for such traffic at lower rates than other agencies, except possibly the coastal and intercoastal water lines. The motor carriers, for very short hauls, had the advantages of generally lower costs, reflected in the lower rates than the other agencies maintained; also the best service. The latter factor, the Commission said, weighed heavily as a competitive factor in the motor carriers' favor within areas of distribution beyond those where their costs were the lowest (*ibid.*, page 555). For example, from the Michigan manufacturing points to Ohio, most of Indiana and Illinois, outside of Chicago, rail transportation of automobiles was virtually nonexistent. The Commission held that unless future rate changes were substantial in amount they would not appear capable of altering in any substantial degree the then existing general distribution of the traffic among the different modes of transportation (*ibid.*, page 539).

As previously noted, the highway common carriers, squeezed by rail rate reductions and contract carrier competition, asked the Commission to exercise its minimum rate-making powers. The Commission denied the application, observing that its minimum rate-making powers had been used sparingly (*ibid.*, page 535); that the application of such powers had been confined to instances in which it had found that a rate was so low as needlessly to sacrifice a carrier's revenue; that methods employed by a carrier to meet competition are primarily a matter of managerial discretion rather than regulation, so long as they are lawful (*ibid.*, page 531); and that "competition often is the process by which the public obtains reasonable rates." (*Ibid.*, page 532.)

The case history of Docket 28190 demonstrates, it is believed, a full-scale application of the contribution or marginal revenue concept to the pricing of the carrier services. It portrays the wide-open operation of market pricing factors in transportation with the fittest mode of transportation taking the overwhelming share of the traffic in the areas where it clearly had the inherent advantages, rates, and services considered. By such division of the traffic, economy and fitness were effectuated with the monetary benefits passed on to the users of the service and to the national economy as a whole. Wasteful transportation (by the less fit carriers) was minimized. Broadly put, the results would seem to be in accord with the national objectives of conservation of resources.

Before terminating this discussion, two additional factors bearing on fitness and economy should be noted. The provision by government of transportation facilities—highways, waterways, and airways, etc.—enormously facilitates entry into the transportation market. To the extent that the rates and charges of the for-hire carriers fail to reflect the economic cost of the public facilities used, their prices are deficient as a test of inherent advantages. Secondly, where heavy out-of-pocket losses are incurred, such as in the rail passenger and LCL services, the imposition of such burdens upon freight traffic seriously affects the carrier's ability to realize on its inherent advantages in the haul of the freight traffic. The rail passenger and LCL out-of-pocket deficits alone require freight rates on the carload traffic which contributes toward such deficits (i.e., more than covers its own out-of-pocket cost) to be 7 per cent higher than otherwise would be necessary to yield the same rate of return.

Summary. From the points developed herein, there may be deduced the following suggested working principles applicable to interagency competitive situations:

1. Fitness and economy are achieved on any given traffic movement when the shipment is so moved as to occasion the lowest sum-total incremental costs (carrier out-of-pocket costs plus shipper supplemental expenses). Carrier rates and services obviously are both involved.

2. The contribution or marginal revenue concept provides a wide scope for differential and incentive pricing through which the inherent transportation advantages of any given mode of transportation may be given recognition, its cost structure considered.

3. Taking the case history of new automobiles in interstate commerce, it appears that market pricing factors when given free play are capable of doing a pretty fair job in dividing business according to fitness and economy, at the same time preserving essential transportation services.

4. Any exercise of the minimum rate-making power by a regulatory agency inevitably results in a "government-created" division of the traffic between the carriers affected. This follows, inasmuch as traffic flow inevitably adjusts itself to any given rate relationship prescribed.

5. The justification for minimum rate orders or restraints would appear to be limited to situations where a "destructive" rate war clearly promises to worsen rather than strengthen the contribution or net revenue position of the fitter mode of transportation, the end result being but to purposelessly shift burdens to other users of the service. A similar problem arises where no one carrier has clear inherent advantages (rates plus service) over another. This situation most often obtains when rail competes with rail or truck with truck. The primary concern here is with the financial soundness of the fitter carrier. Such carrier should not find its net revenues worsened by the operation of the minimum rate authority when compared to that obtainable if price cutting had been allowed to run its normal course.

6. Whenever the "equality of opportunity" concept is invoked by a regulatory agency in the exercise of its minimum rate-making power, this term should be used in the sense of creating an equality of opportunity to fully develop one's economic capacities.[3] The term should not be used, it is believed, in the sense of creating an equal opportunity to divide the traffic or to "keep everybody in business." Minimum rates, if prescribed, should be such as to clearly encourage the traffic to move by the fittest mode of transportation.[4]

The foregoing working principles assume the pursuit of fitness and economy with a single-minded purpose and a minimum of government intervention in the operation of free market forces. There are, however, certain other considerations to be faced, including a reconciliation of fitness and economy with other parts of the national transportation policy.

One practical problem is the adequacy of the information, on costs in particular, upon which inherent advantages as between modes of transportation are determined. Another is the degree of restraint (and respect for out-of-pocket costs as a rate floor) which competing carriers or modes of transportation can be depended upon to voluntarily exercise in their rate cutting. (To the extent that any traffic fails to make the full contribution of which it is economically capable under the marginal revenue concept, it unjustly forces rates upward on other

[3] For a discussion of this theme, see *Big Enterprise in a Competitive System* (Brookings Institution, 1954), A. D. H. Kaplan, p. 40.

[4] In I. & S. 6172, Manufactured Tobacco, Va. and N.C. to Official Points (7/19/54), Division 2 permitted trucks to meet only the rail rate based on 36,000 pound minimum, but not the lower rail incentive rates. This seems to be an important precedent in the recognition of inherent advantages.

traffic upon which the carrier believes it has a monopoly.) The volume of the traffic now being handled at, or below, long-run out-of-pocket costs is disturbing.

Still another issue raised, and one going to national policy, is the consideration which should be given to the need for maintaining some surplus in transportation services and facilities for purposes of defense or simply to sustain some minimum measure of interagency competition. While these and other considerations no doubt are to be weighed, there does not appear to be any reason why they need deter an effective recognition of inherent advantages.

APPENDIX

U.S. RAIL REVENUE CONTRIBUTIONS ABOVE OUT-OF-POCKET COSTS—1951

Commodity Classes	Aggregate Dollar Contribution Above Out-of-Pocket (U.S. Total) (000)	Revenue as a Percentage of Out-of-Pocket Costs
1	2	3
Individual Commodity Classes		
Soybeans	$ 14,669	215
Soybean oil cake	4,835	127
Lettuce	6,933 Def.*	83
Cattle, calves, single deck	8,954 Def.*	83
Meats, fresh, NOS	19,404	134
Bituminous coal	286,494	135

NOTE: Commodity classes herein selected to illustrate some of the range in the relation of rates to long-run out-of-pocket costs.

DISCUSSION

E. W. Clemens: The distinction between marginal cost pricing as advocated by Professor Vickrey, price discrimination in which part of a firm's output is priced at marginal cost, and multiple-product production in which some few products are priced at or near marginal cost is essentially a distinction of degree and method rather than one of substance. Marginal cost pricing is a method by which production is carried to the point where marginal cost equals demand, the deficit, if any, being made up by subsidy. Price discrimination is a method by which production is carried to the point where marginal cost equals demand, the deficit, if any, being made up by a tax, in a manner of speaking, on those customers whose demand is more inelastic. Multiple-product production likewise tends to carry production to the point where marginal cost equals demand price in some limited number of markets. This is done by the normal management procedure of shifting resources between various products, restricting output on those products with a high inelasticity of demand, reducing prices and increasing output on those products with a high elasticity of demand, and "dumping" any idle capacity on the market by producing some products at a negligible profit margin; i.e., producing at marginal cost. (See E. W. Clemens, "Price Discrimination and the Multiple Product Firm," *Review of Economic Studies*, 1950-51, page 1.) In this connection, I might say parenthetically that Joan Robinson's two chapters on price discrimination represent a much more rational approach to the theory of the firm than the more conventional theories of monopolistic or imperfect competition, particularly since in all probability there is in our entire economy no firm which confines itself to a single product or establishes a single price for its output.

So complex are the production and demand functions that marginal cost pricing schemes seldom involve the establishment of a single price as the theory of Professor Hotelling originally assumed. Vickrey's paper contains numerous illustrations of this. In fact, the theoretical benefits of marginal cost pricing can be attained only under a multiple-pricing system. Thus marginal cost pricing and price discrimination both emerge as multiple-pricing systems. The difference lies in the fact that in one case prices are proportioned to some calculated measure of cost or marginal cost and in the other prices are graduated according to elasticity of demand. Professor Vickrey's method is the first and Dr. Edwards' the second. We thus have four general alternatives to average cost pricing: (1) subsidized marginal cost pricing at a single price, a case that can be ignored, (2) subsidized marginal cost pricing at a series of prices, (3) price discrimination without subsidy, and (4) multiple-product production.

Once this is established, marginal cost pricing does not appear as esoteric as it is sometimes made to appear. It represents the norm rather than a deviation from it. Despite the fact that I have been for a long time making this point, I think that the real problems are not the problems of theory but the practical

problems of application, many of which have been pointed out by Professor Vickrey and Dr. Edwards. Differences in view stem primarily from the differing significance we would attach to the many practical considerations involved.

Some of these considerations can be compressed into the single problem of determining marginal cost. The determination of marginal cost is a complex matter. The blithesome simplicity of Lerner's marginal cost concept in the *Economics of Control* must appear almost fantastic to anyone with the slightest familiarity with industrial techniques. Marginal costs in general and in specific situations are extremely difficult to measure and when calculated can be used only under elaborate and cumbersome assumptions. There is at the outset the problem of the proper units to be used (passengers, passenger-miles, cars, trains, etc.). Proper computation is difficult, notwithstanding Professor Vickrey's ingenious formulas. There is also the problem of the size of the price group. In many instances, the selection of one large enough for administrative economy precludes any of the gains of marginal cost pricing. A primary objective of practical rate making is that of keeping the number of groups as small as possible. There is the problem of joint costs and of the degree of jointness. There is the problem of determining and measuring peak demand (hourly, daily, yearly) and the significance that can be attached to random fluctuations of the peak. There are costs of entry and costs of withdrawal. There is the question of the distinction between short-run, long-run, and various series of intermediate-run marginal costs. Is depreciation a function of time or of use? Is it to be based on the past, present, or future costs? The incidental calculation of expected obsolescense resolves itself into a glorified guess at the future. Conceivably you might also have to guess at future interest rates. There is the problem of the proper share of administrative overhead to be included in marginal cost.

There is another consideration which to my knowledge has not been considered. The marginal customer is the customer who will first abandon service with any unfavorable change in circumstances. Service to this customer requiring the commitment of capital, or the incurring of fixed costs, carries with it a high degree of risk. This risk represents a concealed cost that is commonly ignored. The telephone industry, to which Professor Vickrey alludes as a possible further subject of marginal cost pricing, maintains that increasing saturation of telephone service has greatly increased the risks incident to the telephone industry.

The problems of demand are almost as knotty. Price is not an interpersonal measure of utility and there is question as to how far out of its way society should go to see that the marginal user receives service. One can question the social propriety of taxing citizens in New York to subsidize a deep freeze unit in Tennessee—or for that matter, the Aluminum Company of America, if such is the case. On the other hand, discriminatory pricing, or "maximizing the net," and to a lesser extent marginal cost pricing are established on the implied premise that the customer who needs the service most should be charged the highest price. For example, in the transit industry considerations of both demand elasticity and marginal cost would dictate the establishment of peak-time rates that would be highest for the customers least able to pay.

To some extent, the choice boils down to a price system where costs are recovered from users of service as a group, or from society at large through taxes. The ultimate and comparable incidence of a tax on selected users and a tax on society in general would be difficult to trace. I think it would be generally admitted that the efficiency of tax collection, all factors considered, would be pretty low, and the costs involved might well swallow any of the social benefits of marginal cost pricing. This would be particularly true if marginal costs, properly computed, were only slightly below average costs. Apart from this, discriminatory pricing and true marginal cost pricing appear to the customer as one and the same thing and are subject to somewhat the same afflictions.

The load accepted as the marginal load today may be the peak load of tomorrow. If service is at all uncertain, as it would have to be under strict marginal cost pricing, there would be a high degree of risk attached to any commitment to the service made by either buyers or sellers. Abandonment of service would be difficult without serious disruption of buyer economics. This would constitute an unseen element of marginal cost. Buyers are willing to pay a premium for certainty of supply, and producers will take less with certainty of demand. The administrative costs involved in establishing and administering a multiple-price system are considerable. Discriminatory pricing systems, whether based on costs or on elasticity of demand, create consumer resentment.

Opposition to discriminatory pricing policies may be based on something more than uninformed resentment. They may be injurious to the firm practicing them, to the competitors of that firm, and to the customers of that firm. If the weight of bargaining power rests with customers and particularly if the demand for the product of the entire industry is inelastic, the competitive battle between discriminating firms may ruin all, as in the early history of the railroad industry. If the discriminating firm is powerful, it may by a process of discrimination eliminate its competitors one by one, as the old Standard Oil Company once did. If some customers are larger or more powerful than others, they may ruin their rivals by extorting more favorable prices from price discriminating firms, as shippers have done in the past. These situations in multitudinous form have always been matters for public concern. It would be significant, but not necessarily controlling, that price differentials were or were not justified by costs.

I am not taking a stand against the position of either Professor Vickrey or Dr. Edwards, but I am saying that in almost all instances "other considerations" are more important than either "maximization of net" or "marginal cost pricing." Other considerations (to name only a few at random from many industries) include traffic control, urbanization, national defense, the maintenance of several sources of supply, preserving competition, conserving natural resources, and improving the general social and economic welfare of the community. The application of the marginal cost pricing principle, for example, to the utilization of exhaustible natural resources results in a serious perversion of social policy. The many considerations vary with each situation to such an extent as to preclude establishing general principles except in closely prescribed areas of the economy.

JAMES C. NELSON: Dr. Edwards states that relative economy and fitness within transportation are achieved "when the nation's traffic is so distributed among the agencies of transportation that the aggregate costs for all transportation (including shipper supplementary expenses) are lower than they would be under any other basis of distribution." With that concept of best allocation of resources within transport, I am in agreement. The emphasis here upon the historic problem of transport pricing for social economy echoes the fundamental and long-needed re-examination of that subject which carriers, shippers, the trade press, government agencies, and economists are now conducting both at home and abroad. Much good can emerge from this activity, but it should be recognized that pricing for a best allocation, in addition to dividing traffic according to relative cost and fitness, would also, so far as transport is a factor, have to locate agriculture, industry, markets, and population in such manner that no different locational pattern could reduce aggregate costs of production. (For relevant theory, see Tjalling C. Koopmans, "Optimum Utilization of the Transportation System," *Proceedings* of the International Statistical Conferences, Vol. V, 1947, pages 136-145; and Ralph L. Dewey, "Criteria for the Establishment of an Optimum Transportation System," AEA *Papers and Proceedings,* May, 1952, pages 644-653.)

Critical scrutiny must be given the main theoretical principle mentioned by Dr. Edwards as governing rate making. Carriers seeking to maximize their profits undoubtedly engage in mental arithmetic which, if extended to its logical conclusion, would equalize marginal revenues and marginal costs. Equalizing those things will clearly maximize profits where profits can be earned or minimize losses where profits cannot be earned. Assuming that the carrier's demand curve frequently is not horizontal and at different prices may have different elasticities, the rule urged by Dr. Edwards should receive close attention in pricing or in regulating to maximize profits, at least in the short run. The question which arises, however, is whether that rule is equally applicable in dividing traffic according to relative economy and fitness.

The railroads as a whole have not earned exceptional profits in the current high-level economy and they have returned to an excess capacity condition, particularly in passenger operations. More selective and competitive application of the marginal revenue-marginal cost principle—with its accompaniment in railroading, rate discrimination—might well increase volume and reduce excess capacity and also enhance profitability if care is taken not to quote rates below marginal costs. Assuming that most present rail facilities will be needed, to reduce excess capacity by incremental pricing to the extent that demand proves elastic would bring economy in use of durable and other transport resources to that extent. The added profitability (up to a point) would not seem objectionable in view of the demand for greater cost-reducing investment in improved motive power, special and larger freight cars, terminals for trailers on flat cars, new low-cost passenger trains of the Talgo type, and roadway improvement. Hence pricing effort should not only concentrate on demand as influenced by alternative transport agencies but also upon prices that will fully stimulate cost savings from volume and off-peak shipments.

However, as recognized by Dr. Edwards, whether carriers have adequate

knowledge of demand elasticities and of the behavior of costs to apply such pricing very perfectly must be faced. Though accounting and statistical data are favorable in transport, the long hesitation of the rails to quote truly low coach fares even though demand is elastic suggests that interpreting the demand curve is still fraught with uncertainty and risk.

Of greater concern in the problem at hand are the cases which justify doubt that a profitable application of the marginal revenue-marginal cost principle will always divide traffic according to relative economy and fitness. It cannot be overlooked that the existing traffic division has been influenced by the discriminating rate structure which Dr. Edwards has summarized. Thus, if the traffic division is failing to distribute traffic to the agency with the lowest long-term out-of-pocket costs, it might be well to look at the inducement which high discriminating rates, based on the marginal revenue principle, has offered to traffic movements by high-cost agencies.

After neglecting the discriminating effect in developing his example of how marginal revenue-marginal cost equality leads to a maximum revenue contribution, Dr. Edwards subsequently explicitly recognizes that rate discrimination will continue to result from marginal revenue pricing. In addition to bringing maximum justifiable profits, he implies that such discrimination will protect the existing regional pattern of industry. And he also implies that more enlightened discriminatory pricing may bring about an economic traffic division between road and rail. But does he recognize sufficiently the historical wastes that may in part be attributed to discrimination? And does he examine closely enough the cases where gaining the maximum revenue contribution may conflict with a redistribution of traffic to the low-cost agency?

Dr. Edwards properly notes the significant cases where railroads have been rendering services at less than variable costs; hence unprofitably if the cost assignment procedure is correct. If through improved pricing, new equipment, pooling of services, or more efficient management the unprofitable passenger and LCL services cannot be made to yield revenues above variable costs, they should be abandoned even under marginal cost pricing. So long as passenger trains are operated, every effort should be made to stimulate traffic as marginal cost must be extremely low. But it can be argued that the railroads' continued ability to render important areas of service at a loss and still make a profit on all operations has been dependent upon maintenance of high discriminating rates on important segments of traffic. Had the rate structure been less discriminating, perhaps shippers and consumers might not now have to pay millions additional freight revenues to support unprofitable services and society might have gained through an improved allocation of resources.

The possibilities that discrimination may underwrite an inefficient resource allocation do not end there. It is common knowledge that truck lines, particularly on long hauls, have concentrated on classes of traffic on which railroad rates are far above rail out-of-pocket or even fully distributed costs. Hence, to a considerable extent, the current problem whether to lower rail rates drastically below truck rates to encourage traffic flows by the low-cost agency has its origin in the great faith in discriminating pricing in the rail industry. This does not necessarily give cause for casting out discrimination, but it does raise

doubt that the particular discrimination pattern of the past can solve present-day problems. If there is some model of discrimination from marginal revenue pricing that would both maximize railroad profits up to the point that such profits are required and also shift the traffic between agencies so that it would flow over the least-cost agency more frequently than at present, that pattern should be articulated. (*Ibid.*, pages 144-145 and 648, respectively.)

Viewing the allocation problem as it exists today, the serious pricing questions concern the intimate details of how the low-cost agency carriers can reprice their services to encourage traffic for which their agency is low cost and to discourage traffic for which it is high cost (when rates are unprofitable).

Here, a conflict of interest inevitably arises: It concerns whether low-cost carriers would be better off profitwise without some of the competitive traffic and with high rates on remaining traffic than with all competitive traffic at rates low enough to attract it from the high-cost agency. Considering relative service advantages, it may often require marked reductions of present rates to achieve a shift in traffic to the low-cost agency. But if management thinks it more profitable with high rates and less traffic of a given kind, the profit-maximizing rule does not bring carriage of traffic, in the short or even considerably long run, by the agency with lowest marginal costs. Or if management decides to sacrifice present profits with rates low enough to shift all competitive traffic, then traffic flows by the low-cost agency but at low general profitability unless noncompetitive traffic can stand, and regulatory authorities will permit, very high rates upon such traffic.

One possibility for resolving this conflict is to reduce the low-cost agency's rates on competitive traffic as low as necessary, even as low as short-run marginal cost, and to subsidize low-cost carriers for any sacrificed revenue contribution up to a reasonable level. This method should effectively divert traffic to the low-cost agency except where service considerations are controlling and, if other classes of traffic continued to contribute existing revenues over variable costs, it would hold total subsidies below the level under across-the-board marginal cost pricing. Thus the advantages of some discrimination to minimize subsidy and some marginal cost pricing to facilitate relative economy would be combined. But this scheme has some obvious political and economic frailties. The railroad situation is hardly serious enough for public approval of this type of subsidy. And rates as low as marginal costs might not be required to attract traffic to the low-cost agency. Thus, traffic-diverting rates might make positive but varying contributions toward overhead costs and return. Hence, marginal revenue pricing with reasonable discrimination might be preferable after all—but only where it succeeds in shifting traffic to the low-cost agency.

The recent selective rate reductions suggest that in certain cases railroads must assume that enough traffic has been lost that it may pay them to reduce rates sufficiently to regain the traffic. In those cases, the demand curves faced by them may be horizontal down to a price under the high-cost agency's lowest price that will effectively divert the traffic. If the traffic-diverting rate is still above variable cost, it may pay the low-cost agency to lower rates and adhere fully to relative economy pricing. Below the traffic-diverting rate, low-

cost carriers might select rates that maximize the net above variable costs. But what about the many competitive situations in which railroads have not acted to reduce their rates drastically, such as in transcontinental markets with respect to high-rated manufacturers? Here traffic diversion mounts—on long hauls where mass carriers are thought to experience lower costs. Presumably it is not profitable for railroads to stop that diversion, though in time diversion may have a disastrous effect upon their traffic and profitability. In this difficult situation, the devil gets you if you do and he gets you if you don't!

It seems questionable that public support will develop for sufficient restriction of for-hire and private trucking to protect the security of the railroads in the numerous situations where they still carry such a large share of competitive traffic that it is more profitable to continue present discriminatingly high rates than to reduce them to stop diversion. Thus, it may pay the railroads to consider going all the way to a rate system that fully reflects their cost advantages and disadvantages in their rates. Professor Gilbert J. Ponsonby has proposed such a policy for Great Britain, where the railways have been freed of all regulation except maximum rates. Briefly, his proposal is that carload freight be quoted, regardless of commodity, a flat rate per car-mile (recognizing differences in cost occasioned by size of cars, etc.) plus a flat terminal handling charge per car irrespective of distance. Under this plan, rates would still taper and rates on light-loading commodities would be high and those on heavily-loading goods would be low. But discriminatingly high rates would no longer invite truck competition on dense routes where rail costs are lower and would no longer make it possible for rails to continue unprofitable services on light routes and over short hauls where truck costs are lower. Professor Ponsonby doubts that marginal costs are low enough under average costs to make low discriminating rates profitable except in joint-cost cases of return hauls and off-peak travel. He believes such a simplified rate system would automatically shift traffic in accordance with relative economy and fitness and that railroads would still command adequate traffic volumes to operate profitably and at satisfactory utilization rates ("Towards a New Railway Charges Policy," *Journal of the Institute of Transport*, September, 1954, pages 427-433).

This sweeping junking of historic policies may be regarded as too drastic for this country where regional economies have been built upon low value-of-service rates. And some economists will argue that adoption of cost rates would reduce utilization to unprofitable levels even in a growing economy. But at a time when traditional pricing and regulation is under attack and after years of muddling without a solution to the relative economy and fitness problem, it would seem appropriate to consider all major alternatives. (See the comment on page 27 of the *Railway Age*, November 29, 1954, that the Ponsonby "proposal is one that certainly has enough merit in it to warrant a lot of study and discussion.")

Whatever rate policy emerges, vigorous action on several fronts is essential. Otherwise, railroads may face the bleak prospect of continued traffic erosion, higher unit costs from underutilization, higher rates on traffic still wedded to the rails, eventual diversion of that traffic and a continual repetition of that vicious circle, with dismal long-term disinvestment and unprofitability effects.

Fortunately, some encouraging signs of rail action to avoid this outcome exist, such as the selective rate reductions under way, the rapid introduction of trailer-on-flat-car pricing (flat rates on trailers reflecting the rail cost advantage for line hauls), interest in low-cost passenger trains, and improvements in cost control. In addition to such moves, the public must be prepared to have government do its part by assessing adequate user fees for all public transport facilities, by reasonably adjusting regulatory standards, and by insisting upon allowing transport markets to do their important allocation work.

With Dr. Edwards, I believe that rivalry is sufficiently vigorous and widespread that the inherent advantages of all agencies will get a real working out under the competitive organization of transport. Unless a case can be made for the transport company approach, there can be no turning back from recent market developments, only a more enterprising prosecution of market factors—both cost and demand—in pricing.

AMERICAN ECONOMIC ASSOCIATION

PROCEEDINGS

OF THE

SIXTY-SEVENTH

ANNUAL

MEETING

•

•

DETROIT, MICHIGAN

DECEMBER 28-30, 1954

PROCEEDINGS OF THE AMERICAN ECONOMIC ASSOCIATION

ANNUAL BUSINESS MEETING, DECEMBER 30, 1954
HOTEL STATLER, DETROIT, MICHIGAN

The Sixty-seventh Annual Business Meeting of the Association was held in the Wayne Room, Hotel Statler, December 30, 1954. The meeting, which was well attended, was called to order at 5:00 P.M. by President Simon Kuznets. After his introductory remarks, outlining the order of business, Professor Kuznets called for the approval of the minutes of the business meeting of December 30, 1953, and the ratification of the Executive Committee actions and acceptance of the reports of the Association's officers and committees, all of which are published in the "Proceedings." A formal vote of approval was passed.

The chief events of the year and major activities of the Association as well as the financial operations, investment holdings, and present status of the Association's finances were presented by the Secretary-Treasurer, James Washington Bell, and his report was accepted.

The Managing Editor of the *American Economic Review*, Bernard F. Haley, summarized the work of the Editorial Board and the Editorial Office in producing the *Review*. He noted some of the many problems concerning the size and contents of the *Review* and again called attention to the usefulness of his panel of advisers, whose names appear at the end of the Report of the Managing Editor.

Only the work of two committees was selected for presentation at this meeting; namely, that of the Committee on Economics in Teacher Education and the *Ad Hoc* Committee on the Implementation of the Bowen Report. Because these matters are of general concern to our members, the business meeting was considered an appropriate time to publicize them. A brief discussion of the relation of the Association to economic education from the floor followed the presentation of these reports. Brief mention was also made of matters relating to the status of the profession. Academic freedom in its various aspects continues to be of concern to the officers of the Association. Attention is being given to the subject of freedom of teaching, research, and publication.

Information concerning the work of committees may be found in comments in the Secretary's Report or reports of the committee chairmen. Reports of officers, committees, and council representatives are printed below, as follows: Reports of the Secretary (page 646); Treasurer (page 659); Finance Committee (page 662); Auditor (page 665); Managing Editor (page 671); of the Committee on Research and Publications, Simeon E. Leland, Acting Chairman (page 675); of the Committee on the Status of the Profession, I. L. Sharfman, Chairman (page 677); of the *Ad Hoc* Committee on Economics in Teacher Education, B. W. Lewis, Chairman (page 685); and of our representatives to the International Economic Association, H. S. Ellis (page

687), the Social Science Research Council, G. W. Stocking (page 689), the American Council of Learned Societies, F. H. Knight (page 692), and the National Bureau of Economic Research (page 694).

The Secretary reported that a preference ballot was being circulated with the membership dues bills, asking members to express their choice of time and place of future meetings beyond those presently committed.

The Committee on Elections report and the certification of the election of new officers for the year 1955 were presented by the Secretary, as follows:

I hereby certify, in accordance with the bylaws on election procedure, the results of the recent balloting and present the reports of the Nominating Committee and the Committee on Elections.

The Nominating Committee, consisting of Morris A. Copeland, Cornell University, Chairman, Howard R. Bowen, Williams College, Mary Jean Bowman, University of Kentucky, Ewan Clague, Department of Labor, Martin R. Gainsbrugh, National Industrial Conference Board, and William J. Fellner, Yale University, presented to the Secretary the list of nominees for the respective offices:

For President
John D. Black

For Vice-Presidents
Earl J. Hamilton
Abraham D. H. Kaplan
Paul A. Samuelson
George W. Terborgh

For Executive Committee
Milton Friedman
Everett E. Hagen
Ruth P. Mack
Lawrence H. Seltzer

The Committee on Elections (Frank G. Dickinson, American Medical Association, Chairman, S. Morris Livingston, Standard Oil Company, and James Washington Bell, Northwestern University) prepared biographical sketches of the candidates and ballots were distributed early in November. The canvass of ballots was made on December 13, 1954, and the results were filed with the Secretary.

From the report of the Committee on Elections, I have the following information:

Number of envelopes without names for identification	52
Number received too late	24
Number of defective ballots	—
Number of legal ballots	2,879
Number of returns from the mail ballot	2,955

On the basis of the canvass of the votes cast, I certify that the following persons have been duly elected to the respective offices:

President (for a term of one year)
John D. Black
Vice-Presidents (for a term of one year)
Earl J. Hamilton
Paul A. Samuelson
Members of the Executive Committee (for a term of three years)
Milton Friedman
Ruth P. Mack

The results of the election having been announced, retiring President Kuznets presented President-elect John D. Black, who responded with brief remarks. He expressed appreciation of the great honor and also of the heavy responsibility of this office. He remarked that his predecessors had set high standards of accomplishment and that only one with a strong sense of duty and obligation could hope to do as well in making the work of the economist important and useful in the world. Referring to his own field of specialization,

he reminded us that he will be the fourth president who has also served as president of the American Farm Economic Association, the others being T. N. Carver, E. G. Nourse, and J. S. Davis.

The lateness of the hour prevented discussion of any new business from the floor, and President Black called for the final item on the agenda; namely, the Report of the Resolutions Committee. The resolutions which follow were read by Professor Blodgett and were approved unanimously:

The Association is greatly indebted to President Simon Kuznets, who bore the major responsibility for the preparation of the program of this annual meeting, and to the members of the Executive Committee and all others who so ably assisted him in this difficult and time-consuming task.

The Association expresses its thanks to Edward L. Cushman, Chairman, and Ruth C. Barnes, Secretary, of the Committee on Local Arrangements, and their several associates on this committee for their effective attention to the innumerable technical and practical problems associated with the holding of this large gathering. Special appreciation is also due to the various local institutions and agencies, governmental and private, including the Automobile Manufacturers' Association and General Motors Corporation, for their most helpful assistance in making arrangements for these sessions. The Association is grateful to the management and personnel of the Statler Hotel for ministering to the comfort of the delegates and visitors to these meetings and to the press and other agencies of communication for their coverage of the proceedings.

Acknowledgment is also made of the co-operation of the ten other professional organizations, meeting simultaneously in this city, in the making of a co-ordinated and constructive joint program.

Finally, the Association extends its sincere thanks to its able Secretary, James Washington Bell, and his staff for their continued and effective contribution to the arrangement of the annual meetings over many years.

Ralph H. Blodgett, *Chairman*
Archibald M. McIsaac
James C. Nelson

The meeting was adjourned at 6:00 P.M.

JAMES WASHINGTON BELL, *Secretary*

REPORT OF THE SECRETARY FOR THE YEAR 1954

The official acts of the Association during the year are recorded in the minutes of the Executive Committee. These are presented herewith, followed by a summary of the year's operations and activities, with comments and interpretations.

MINUTES OF EXECUTIVE COMMITTEE MEETINGS

1. Minutes of the spring meeting held in Rye, New York, April 2-3, 1954:

The *second meeting* of the *1954 Executive Committee* was held at the Westchester Country Club, Rye, New York, April 2-3, 1954. The following were present: Simon Kuznets, presiding, and J. W. Bell, Roy Blough, K. E. Boulding, Gerhard Colm, B. F. Haley, L. R Reynolds, Arthur Smithies, and G. J. Stigler. Absent were: N. S. Buchanan, C. B. Hoover, J. H. Williams, and D. M. Wright. Attending as members of the Nominating Committee were: H. R. Bowen, M. J. Bowman, Ewan Clague, M. A. Copeland, and W. J. Fellner (M. R. Gainsbrugh absent); and as guests, Pendleton Herring, F. H. Knight, and J. P. Miller.

1. *President's Remarks* (Simon Kuznets). The meeting was called to order at 10:00 A.M. Professor Kuznets outlined the agenda and the procedure to be followed.

2. *Minutes.* The minutes of the December 28 and 30, 1953, meetings were reviewed and, with minor corrections, were approved as presented in page proof.

3 and 4. *Reports of the Secretary, the Treasurer, and the Finance Committee* (J W Bell). Although the final report of the Local Arrangements Committee had not yet been received, enough details were at hand to enable us to appraise the results of the Washington meeting. Attendance was especially large. All available facilities were taxed to the full, and despite a little friction here and there, the arrangements proved highly satisfactory. Financial results exceeded expectations. Our experience was reviewed in the light of the prospective problems we face in planning the Detroit meeting.

Membership statistics were discussed and some concern was expressed at the regressive or flattening-out character of these figures, for both members and subscribers. The Secretary presented possible explanations of these curves. Our exchange and complimentary lists were reviewed and the Secretary's proposal to revise our complimentary subscribers list was approved.

The *Papers and Proceedings* volume for May, 1954, promises to be even larger and costlier than last year's volume. Plans were discussed for publishing an annual supplement to the *Handbook* and for a revised *Directory* in 1955 or 1956

The financial results of the "Readings Series" and other sponsored publications were reported, and the Secretary was authorized to go ahead with plans to co-operate with Richard D. Irwin, Inc., in disposing of surplus inventory of Volumes I-V of the "Readings Series."

There were no significant changes to report in financial conditions since December nor in our investment portfolio. At present, we are in a strong cash and investment position

A summary of committee activities indicated the status of standing and *ad hoc* committees upon which reports were forthcoming or, in the case of committees which have been discharged, where action might be called for.

5. *Report of the Managing Editor* (B. F. Haley). Professor Haley spoke briefly about the work of the Editorial Board, the flow of manuscript, the exchange list, and his plans to use foreign correspondents. He submitted a panel of names from which two appointments are to be made at the December meeting to fill the vacancies that will be created on the Editorial Board by the expiration of the terms of J. S. Bain and H. M. Somers.

6. *Reports of Standing and Special Committees.*

6a) *Research and Publications* (J. P. Miller). The following items, which had been taken up by this Committee at a meeting held in New York City, March 28, were discussed and where action was taken, it is so indicated:

Progress was reported on the fiscal policy volume of the "Readings Series" (Arthur Smithies and J. K. Butters, Editors).

The William Jaffé translation of Walras is now in the hands of the printer and the English edition should be out soon. The American edition will be announced for fall distribution.

The Committee recommended that the George Allen & Unwin, Ltd., proposal to undertake the translation of Silvio Gesell's *The Natural Economic Order* be rejected. The Academic Reprint proposal of joint sponsorship of a reprint of the Hull edition of the *Economic Writings of Sir William Petty* was also rejected. It was agreed that such a reprint of Petty would be desirable but that the market would not justify our becoming financially involved.

Proposals to compile economic bibliographies were considered, and there was agreement with the Committee's conclusion that general bibliographies should not be undertaken but that exceptions might be made for special bibliographies in connection with other projects sponsored by us; for instance, in connection with the proposed project on economic growth and development (see below).

On recommendation of Professor Miller's Committee, it was agreed that the Executive Committee authorize the preparation of a review article on bibliographical sources for research in economics which would be published in the *American Economic Review*, either as an article or a supplement. Reprints of this annotated "bibliography of bibliographies" would then be made available for the use of librarians and graduate students. An honorarium of $300 was appropriated to be used if necessary in order to get this job done.

To facilitate the use of the *American Economic Review* and the *Papers and Proceedings*, the Committee recommended that a cumulative index, by author and subject, of Volumes I-XLIV be prepared and that we contemplate future cumulative indexes every decade or so. The Committee was asked to draw up plans and estimate costs of this project, with the aid of B. F. Haley.

A proposal that the Association embark on a series of republication volumes on economic growth was discussed at length and the consensus seemed to be that the Committee be encouraged to reformulate its proposals, not along the line of publishing a series of six volumes, but of presenting a prospectus of one volume of readings or possibly two. This proposal, in effect, would widen the purposes of the Committee in that it involves not only the encouragement of research efforts but their direction as well. The Committee was asked to report a detailed plan for presentation at the December meeting.

In connection with the operations of the SSRC, Professor Miller and Dr. Pendleton Herring reported that the small research grants program for which Ford Foundation support was sought had become part of a larger move, involving the several social sciences. Also, the proposed handbook on the use and application of empirical techniques in economic research is now a project of the Agricultural Committee of the SSRC.

New appointments to the Committee were made as follows: R A. Gordon, to succeed G. W. Stocking (term, 1955-57); M F. Millikan, to fill the vacancy due to expiration of S. E. Leland's term (term, 1954-56); and Alexander Gerschenkron as an additional member of the Committee (term, 1954-56).

An additional sum of $500 was appropriated for operating expenses of the Committee.

6b) *International Co-operation; the IEA* (Gottfried Haberler). A communication from Howard S. Ellis was read. Professor Ellis, President of the IEA, requested the Association's recognition of an IEA-UNESCO volume on *Recent Trends in Economics*, embracing five or six essays prepared by representative authors familiar with trends of economic research in their respective countries Under pressure for prompt action, Professor Ellis invited Rutledge Vining, of the University of Virginia, to prepare the essay on recent trends in economics in the United States. He did this in consultation with colleagues accessible at the time and now asks the officers of the AEA to express their approval of the selection of the author and requests, furthermore, that the President of the AEA write a short introductory note to this essay. No formal action was taken on this request, but the Secretary was instructed to write Professor Ellis, suggesting that his appointment of the author of the essay in this volume is in keeping with the implicit powers delegated by the Association to its representative to the IEA but that the preface to the article be revised so as to indicate merely that the author has been selected by the President of the IEA and the AEA delegate to that organization on his own judgment and responsibility.

The IEA-UNESCO sponsored report, *Teaching of Economics*, should soon be ready for distribution.

It was VOTED to ask a small *ad hoc* committee to prepare an appraisal of the activities of the IEA and of the AEA's participation in the international organization and report its findings to the Executive Committee at its next meeting.

It was VOTED to continue for another year the annual support of the IEA in the amount of double the annual dues; namely, $400.

The next IEA conference will be held at Seelisburg, Switzerland, in August-September, 1954, and the subject will be on wages. L. G. Reynolds, J. T. Dunlop, and Clark Kerr have been invited to attend.

The method of selection of AEA representatives to IEA was discussed. The general sentiment seemed to favor a year-to-year appointment rather than the six-year terms provided for in the IEA charter, but since the appointment of alternates is already provided for, no action was deemed necessary. (See *Papers and Proceedings*, May, 1950, page 594.)

6c) *Honors and Awards* (N. S. Buchanan). No formal report was received from the Committee. After a protracted discussion of the problem of selecting candidates for the J. B. Clark award, it was agreed that we should ask the Committee to reconsider its procedure and it was suggested that sufficient preparation be made in advance of their December meeting to enable them to complete a panel of nominees from which definite recommendations can be submitted to the Executive Committee at the time of its spring meeting in 1955. No award will be made in 1954, and the next award will follow the original schedule.

Professors J. Douglas Brown and Jacob Marschak were selected to succeed Professors G. L. Bach and E. S. Shaw at the expiration of their terms at year-end, 1954.

6d) *Foreign Honorary Members* (W. W. Leontief). No report was submitted by this Committee at this time. With a maximum limit of twenty-five foreign honorary members and twenty incumbents, there remain five vacancies. The Secretary was instructed to ask the Committee to submit the list of names under consideration, together with data concerning qualifications, in case they have no definite recommendations to make at our next meeting.

6e) *Nominating* (M. A. Copeland). At 8:30 P.M. the Executive and the Nominating Committees were constituted as an Electoral College. The report of the Nominating Committee was presented by Professor Copeland. After considering and agreeing upon the nominee for the presidency, the Secretary called and got acceptance from the candidate over long distance telephone. The panel of candidates for nomination to office for vice-presidents and members of the Executive Committee was considered and appointments were made of our representatives to ACLS and SSRC. It was ordered that the whole slate be published in the June number of the *American Economic Review*.

7. *Reports of Council Representatives.*

7a) *ACLS* (F. H. Knight). Professor Knight was selected for another four-year term as our representative. Time did not permit full discussion of the recent meetings of the Council and the Conference of Secretaries (held at Rye, New York, January 20-22). No significant changes in policy or new events need be added to the report submitted and published in the "Proceedings."

7b) *SSRC* (J. P. Miller). In addition to the report of Professor Miller, who described the routine operations of the Council and activities of its more important committees, we listened to Dr. Pendleton Herring describe plans and prospects of the Council, especially the Ford Foundation subsidized summer session training institutes and Rockefeller Foundation faculty research program. R. A. Gordon was selected to succeed G. W. Stocking upon the expiration of the latter's term at year-end 1954.

7c) *NBER* (J. H. Williams). No report.

8. *Annual Meetings.*

8a) Invitations for our 1956 and 1957 meetings were received from practically all large cities in the central and eastern states It was VOTED to meet in Cleveland, December 27-30, 1956, and in Philadelphia, December 27-30, 1957.

8b) The problems of local arrangements for the Detroit meeting were briefly discussed Among these problems are the degree of jointness or independence of our meetings, program, registration, exhibits, advertising, and the use of the US Employment Service again this year.

9. *Miscellaneous and Unfinished Business.*

9a) After listening to H. R. Bowen and J. P. Miller and the Secretary report on the Association's activities in relation to economic education, it was agreed that we should appoint an exploratory group (H. R. Bowen to suggest names) to study and report on continuation projects suggested by the reports on graduate training in economics, undergraduate teaching of economics, and our activities in co-operation with the Commission on Economics in Teacher Education.

Arthur Smithies, responding to President Kuznets' request in December, reported on the petitions recommending certification of economists. He read a number of letters in answer to his questionnaire and on the basis of this evidence recommended no action by our

Committee. No action was taken and the letters were filed with the Secretary.

9*b* and *c*) The Keezer *ad hoc* committee report recommending that a committee on public issues be not reconstituted was taken up along with the Wilcox report on the freedom of teaching, research, and publication in economics. President Kuznets agreed to follow up the latter committee's recommendation that a standing committee be appointed on the status of the profession, with a charge that it prepare an annual report which might involve not only questions of academic freedom and loyalty oaths but also representations on public issues and all other matters considered appropriate.

10. *New Business.* The balance of the meeting was devoted to the preparation of a preliminary draft of the program for the 1954 meeting.

The meeting was adjourned at 12:30 P.M., April 3.

2. Minutes of the Christmas meetings held in Detroit, Michigan, December 28 and 30, 1954:

The *third meeting* of the *1954 Executive Committee* was called to order at 10:00 A.M. at Hotel Statler, Detroit, December 28, 1954, Simon Kuznets presiding. Others present were: J. W. Bell, Roy Blough, Gerhard Colm, B. F. Haley, C. B. Hoover, L. G. Reynolds, and Arthur Smithies. Also present, as guests, were: J. D. Black, Ruth Mack, G. L. Bach, F. H. Knight, S. E. Leland, I. L. Sharfman, and G. W. Stocking. Absent were: K. E. Boulding, N. S. Buchanan, G. J. Stigler, and D. M. Wright.

The *first meeting* of the *1955 Executive Committee* was held on December 30, at 6:00 P.M., with President J. D. Black presiding. Others present were: J. W. Bell, Gerhard Colm, B. F. Haley, C. B. Hoover, and Simon Kuznets. Attending, as guests, were: Roy Blough, B. W. Lewis, L. G. Reynolds, and F. H. Knight. Absent were: N. S. Buchanan, Milton Friedman, E. J. Hamilton, Ruth Mack, P. A. Samuelson, G. J. Stigler, and D. M. Wright.

The account of the proceedings given below does not follow the chronological order of business but treats the sequence of items as they were listed on the agenda.

1. *President's Remarks* (Simon Kuznets). After the meeting was called to order, the items on the agenda were outlined and rearranged so as to take up first those matters representing business that should appropriately be acted upon by year-end 1954, leaving others on the table for consideration by the 1955 Executive Committee.

2. *Minutes.* The minutes of the April 2-3, 1954, meeting, held at the Westchester Country Club in Rye, New York, were approved, with minor corrections, in the form in which they had been distributed.

3 and 4. *Reports of the Secretary-Treasurer, the Finance Committee, and the Auditor* (J. W. Bell). Excerpts from the Secretary's Report were presented, summarizing the chief activities of the year and outlining the status of operations in progress; i.e., the annual meeting, publications, special projects, reports of committees and of council representatives. The Secretary was asked to report at the spring meeting his plans for a revision of the next *Directory*.

The financial condition of the Association was described. Several items on the summary statements of income-expense and balance-sheet accounts which were distributed called for explanation and discussion. Our investment holdings were reviewed, changes made during the year were explained, and our investment policy was discussed. Copies of the Auditor's Report were distributed for examination. Details of financial and investment operations may be found in the reports published below.

Present incumbents of the Finance Committee (Messrs Osgood and Farnham) were re-elected for another year, as were the auditors, David Himmelblau & Co. The vote instructed the Secretary to extend to these members an expression of confidence and warm appreciation of their helpful services.

A resolution was VOTED to renew authorization of power to buy and sell securities on the part of the Secretary-Treasurer as nominee of the Association. The purpose of this resolution was to bring up to date an action taken March 21, 1936.

5. *Report of the Managing Editor* (B. F. Haley). A report was presented (see below) from which certain items were submitted for discussion; i.e., the flow of manuscripts and the size and content of the *Review*, reviews of foreign books and the use made of foreign correspondents, aid sought from a panel of members to relieve those on the Editorial Board. Without formal vote, there was uniform expression by members of the Executive Committee favoring more latitude in the use of the Editor's discretion in enlarging the size of the *Review* some twenty to thirty pages. Such expansion would permit more pages for articles and reviews of selected foreign books.

The appointment of Carl Kaysen and R. B. Goode for three-year terms was APPROVED. They succeed J. S. Bain and H. M. Somers, whose terms expire.

6. ***Reports of Standing and Special Committees.***

6a) ***Committee on Research and Publications*** (S. E. Leland, acting for J. P. Miller). The Committee met in New York City March 28, 1954, and again during the annual meetings at Detroit. S. E. Leland summarized the status of our publication projects, i.e., the "Survey," "Readings," and "Translation" series, and outlined projects under consideration by the Committee (see report below). He reported that a bibliographical article for the *AER,* authorized at the April meeting, has been commissioned and that the Committee is studying B. F. Haley's helpful estimates on publication costs of a cumulative index of articles and papers of the AEA, 1911 to date. New proposals for a *Survey* Volume III on methodology or economics in action is under consideration, as are subsequent volumes in the "Translation Series." William Jaffé's project on the life and works of Walras was discussed.

At the present time, there is a balance of $644.74 available for the work of this Committee, plus the $300.00 appropriated for the economic bibliography article.

6b) *Ad Hoc Committee on Economics in Teacher Education* (B. W. Lewis). A brief report (see below) was read, describing the activities of this Committee and recommending that this Committee be continued as an *ad hoc* Committee on Economic Education and be instructed to prepare for the spring meeting recommendations on the need for and character of the appropriate scope of action by the Association on the different levels of education. The report was accepted with the deletion of "the teaching of economics at the college level and" in the last paragraph.

6c) *Committee on International Co-operation* (Gottfried Haberler); *International Economic Association* (H. S. Ellis). Due to exigencies beyond control, no reports were received from either Gottfried Haberler or H. S. Ellis. Our relations to the IEA were discussed and those present who had attended conferences of the IEA gave their appraisal of the value of these sessions and of the work of the IEA. Although no action was taken, it was agreed that our relations to IEA should continue as in the past but that our organization set-up should be revised, at least so far as our representatives are concerned. These members are appointed for six-year terms but in practice *ad hoc* representatives are selected from members who happen to be in Europe at the time. It would seem more logical to appoint delegates to special meetings. Action was delayed, pending receipt of report from H. S. Ellis, and it was suggested that copies might be prepared for circulation before the spring meeting if organization matters were considered in the report. The report, subsequently received and published below, indicates that the size of the IEA Council has been reduced and that the AEA is to select but two instead of four representatives and recommends that two of its present four representatives be appointed alternates rather than members and that thereafter only two members be appointed.

6d) *Committee on Honors and Awards* (N. S. Buchanan). G. L. Bach, reporting in N. S. Buchanan's absence, explained that the difficulties encountered by last year's Committee in submitting recommendations for honors and awards could not be resolved without reviewing the whole question of the desirability of making such grants at all. The Committee was asked to continue its work, perhaps reviewing the Slichter report published in the 1945 "Proceedings." When the awards were originally instituted, such misgivings as the Committee now holds were exhaustively discussed. The chairman will be expected to attend the spring meeting and report recommendations of the Committee on Honors and Awards.

6e) *Committee on Foreign Honorary Members* (W. W. Leontief). In the absence of W. W. Leontief, the one-page letter was read, recommending consideration of some representative of one of the underdeveloped countries for inclusion in our roster of foreign honorary members, and an additional representative from Germany. As possible alternates, the names of two prominent economists from other lands were added. Vitae of the principal candidates were attached. No action was taken. It was suggested that the field of candidates be broadened and that additional names be submitted for consideration at the spring meeting.

6f) ***Ad Hoc Committee on the Status of the Profession*** (I. L. Sharfman). The carefully prepared report was read (published below), reviewing the work of last year's Committee on Freedom of Teaching, Research, and Publication in Economics (see *Papers and Proceedings,* May, 1954, pages 733-737). This committee had recommended further exploration of the "need and scope of activity" for a standing committee on the status of the profession. In the light of the general situation concerning academic freedom and of the developments of the past year, the present Committee recommended such a standing

committee, with its scope of activity limited, for the time being at least, to the preparation and publication of reports. The Committee also suggested that members of the Association be afforded an opportunity to discuss crucial problems of academic freedom and civil liberties at annual meetings.

After a protracted discussion of the report, it was VOTED to discharge the Committee, with thanks, and the matter was left on the table for further consideration by the Executive Committee at its spring meeting.

6g) *Ad Hoc Committee on Implementation of the Bowen Report* (G. L. Bach). The Committee was not prepared to submit a final report, but G. L. Bach was invited to give an account of the present thinking of its members concerning the principal issues involved. It appeared that little agreement had been reached during preliminary discussions, although all members acknowledged our professional responsibilities with regard to the training of economists and all favored continued study of the recommendations contained in the report. The chairman promised to have a report in the hands of the members of the Executive Committee well in advance of the spring meeting.

6h) *Nominating Committee* (J. D. Black). As a preliminary step in the election process for next year's officers (see bylaws), J. D. Black discussed names of appropriate candidates for the new Nominating Committee. E. G. Nourse was appointed chairman of the 1955 Nominating Committee.

7. *Reports from Council Representatives.*

7a) *ACLS* (F. H. Knight). In view of the rather critical status of this Council with respect to financial support by the foundations, the general question was raised: What are the functions of the national organization devoted to the advancement of human studies at this time and what stake does the AEA have in its survival? F. H. Knight described briefly the origin and history of the Council, its accomplishments, our relations to it, and the circumstances leading up to the present situation. This was the subject of discussion at last year's Council meeting and promises to be the main item on this year's agenda. So far as financial aid was concerned, Frank Knight suggested that direct individual contributing membership would probably prove futile, as well as would solicitations for voluntary contributions from our membership. The matter was left in its present status; namely, to offer to pay our representatives' expenses to ACLS meetings.

Statements of the directors of the ACLS and of the SSRC and other councils, prompted by the Congressional committee investigation of tax-exempt foundations, were alluded to in this connection.

7b) *SSRC* (G. W. Stocking). No oral report was presented at the meeting but one is printed in the "Proceedings."

7c) *NBER* (J. H. Willams). A report is published in these "Proceedings."

8. *Annual Meetings* The time and place of our commitments for subsequent annual meetings were reviewed and confirmed: 1955, New York, New York, Hotel Commodore (joint); 1956, Cleveland, Hotel Cleveland (independent); 1957, Philadelphia, Bellevue-Stratford Hotel (independent); and 1958, Chicago, Palmer House (joint). All meetings are scheduled for December 28-30, except for Chicago, 1958, where dates have been shifted to December 27-29 in order to avoid a conflict with another large organization meeting at the Palmer House December 30-January 1.

The Secretary reported that liaison is maintained with others of the allied social science group at an annually scheduled breakfast conference. He also reported that George Garvy, of the Federal Reserve Bank of New York, had accepted our invitation to serve as chairman of the Committee on Local Arrangements for New York, 1955. A questionnaire slip is being sent to our members along with dues bills in order to poll the sentiment with respect to preferred time, place, and character of meetings after present commitments have run out. The last survey of this kind was conducted in 1945. This mail poll will be processed and results reported at the spring meeting.

9. *Miscellaneous Unfinished Business.* A letter from K. E. Boulding again raised the question of our affiliation with the AAAS. Time did not permit a review of this perennial matter.

A discussion of subjects for new AEA activities was postponed.

The balance of the meeting was devoted to a discussion of program plans for 1955. During J. D. Black's absence (mission to Pakistan), certain members of the Executive Committee agreed to take initial steps in organizing segments of the program.

The meeting was adjourned at 8:00 P.M.

Activities and Operations

Although no spectacular events marked this year's developments, the year has been one of steady growth and much has been accomplished. Our membership, though increasing at a regressive rate, includes the great bulk of formally trained economists and we maintain our position as the largest and strongest learned or professional society in our field. This position we enjoy by virtue of services rendered to our members in the form of meetings, publications (our own and cosponsored ones), committee activities, and collaboration with other groups at home and abroad—groups having common interests and purposes.

The annual meetings in Detroit were well attended, registration of our own membership totaling 1,175 and a gross paid registration of all associations totaling 1,636. (For statistics of past meetings, see 1953 *Handbook*, page 173.) Accommodations were adequate and the excellent management by a capable local arrangements committee insured smooth operations in all departments. The quality of papers presented maintained the high standards of the past—a judgment which will, we hope, be confirmed by a favorable reception of the May *Papers and Proceedings*. Already plans for the 1955 meeting are beginning to take shape.

The Managing Editor of the *Review* reports a continuous flow of high-quality manuscript and asks authority to enlarge the size of the four big issues of our quarterly publication to permit more space for main articles and for reviews of important foreign books. Except for a twelve-page supplement to the 1953 *Handbook*, no supplementary reports were mailed to our members this year. However, our "consumers" are well treated and get ample money's worth for dues and subscriptions paid. No increase in the present $6.00 charges is contemplated.

Standing Committees on Research and Publications, International Co-operation, Honors and Awards, and Foreign Honorary Members continue to function actively and *Ad Hoc* Committees on Economics in Teacher Education, the Status of the Profession, and the Implementation of the Bowen Report have been investigating the feasibility of our promoting or developing new lines of activity. Only brief references will be made in this report, since the reports of the committees themselves appear below and the minutes of the Executive Committee are reported more fully than usual because of the unavoidable absence of many of its members.

Annual Meetings. Commitments for time and place of future meetings have been made through 1958 (see minutes of December, 1954).

Membership. Exhibit II following this report shows total membership of 7,500 and subscribers of nearly 3,000. The net gain of 200, following a net gain of about the same number as last year, would seem to indicate that we have reached a plateau of growth. We are not satisfied with this record and believe that greater effort could be made to enroll more new members. Many of our younger colleagues as well as older members of the staff have for reasons of inertia or other not performed what should be considered a logical professional function. College and university catalogues, publishers' mailing lists, the National Roster of Scientific and Specialized Personnel, the recent survey of highly

trained personnel, and other sources (see Secretary's Report, May, 1951, page 769, and 1953, pages 566-567, and the "Report on Graduate Education in Economics," pages 22-25) provide evidence to show that there are hundreds, perhaps many hundreds, of logical prospects, many of whom need only to be solicited to induce them to become members. A membership drive might do the business but much can be accomplished, as was indicated in this report last year, by co-operative effort on the part of members. We suggest that you ask for copies of our information booklet and that you distribute to those interested.

Geographical Distribution. The distribution of members and subscribers remains much the same. (See May, 1952, *Papers and Proceedings*, page 720, for brief analysis and reference to previous counts and the 1953 *Handbook*, pages 180-181, for latest published figures.)

Publications. The Association publishes the quarterly *American Economic Review*, the annual *Papers and Proceedings* volume, and occasional supplements, directories and handbooks and an annually revised information booklet.

American Economic Review. The four issues of this year's volume totaled 1,232 pages. Total number of copies printed was 11,000 and the cost of publication $25,436.52. The Managing Editor's Report contains a detailed description of contents (articles, communications, reviews, notes, and the like), costs and the budget for 1955.

We continue a liberal policy in granting permission to quote and reprint materials both from the *Review* and the *Papers and Proceedings*.

The series of photographs and biographical sketches of past presidents has been completed; that is, we have caught up with current incumbents. It is proposed to continue the series until we have included all past editors, secretaries, and treasurers.

The section on "Vacancies and Applications" still serves a useful purpose, after fifteen years of experience.

Papers and Proceedings. The May, 1954, volume contains 765 pages, published at a cost of $13,932.96. We look forward to a slight reduction in the size of the current volume being prepared.

Handbook or Directory. An eleven-page supplement to the 1953 *Handbook* was mailed to our members in July of 1954. It contained names and addresses of new members added to our rolls between April 15, 1953, and June 1, 1954. The next edition will be a volume in the form of a "who's who" *Directory*, such as we published last in 1948, and plans are to issue this in 1955 or 1956.

The sixteen-page information booklet, revised annually, will soon be available for distribution to officers and to prospective members and others interested in learning about the purposes and activities of the Association.

Committee Activities. A roster of members of all standing and *ad hoc* committees is found at the end of this report.

Committee on Research and Publications (S. E. Leland, Acting Chairman). The report published below calls attention to the appearance of William Jaffé's translation of Walras, *Elements d'Economie Politique Pure.* This long-awaited volume is receiving very favorable attention. Volume VII of the "Readings Series," on *Fiscal Policy* (Arthur Smithies and J. K. Butters, editors), is now

completed and should be off the press shortly. The IEA-UNESCO volume on the *University Teaching of Social Sciences: Economics*, which the American Economic Association and the Royal Economic Society helped to underwrite, is now available at a preferred price to members (see note and advertisements in the *American Economic Review*). The volume contains articles on the content of economics curricula and methods of teaching in several foreign countries and should be of interest to all teachers of economics.

In order to clear out excess inventory of Volumes I-V of the "Readings Series," Richard D. Irwin, Inc., last fall announced a sale at reduced prices to members. The results have been gratifying. This is a special opportunity to fill gaps or to start a complete set of this series.

Ad Hoc Committee on Economics in Teacher Education (B. W. Lewis, Chairman). The report of this Committee (see below) raises a number of questions which are of interest to a large number of our members. For instance, should we, as a professional association, co-operate more directly with teachers associations in their efforts to improve the teaching of economics in secondary schools; should we encourage or recognize in some way or offer our facilities to aid in the important work of economic education being done in summer workshops; should we offer our facilities to help organize or give publicity to the numerous educational conferences conducted by business corporations and trade-unions. A 150-page booklet on *Economics in General Education*, which represents proceedings of a conference held at Riverdale, New York, August 22-September 3, 1954, has just been issued by the Joint Council on Economic Education. Some effort may be made to learn who amongst our members are interested in these questions. If enough interest is expressed to warrant the effort and expense involved, we may include an item on this subject in the next *Directory* questionnaire, or we may even prepare a special mailing.

Committee on International Co-operation (Gottfried Haberler, Chairman); *International Economic Association* (H. S. Ellis). H. S. Ellis, in a report published in the "Proceedings," gives an account of the IEA activities and certain changes in the organization that are taking place. Bulletin No. 2, 1954, of the Association Francaise de Science Économique, is almost entirely devoted to the description of the IEA summer conferences held since 1951, to its membership, organization, and publications. We have made previous note of the first three volumes of the *International Economic Papers*, published by Macmillan, London, but available in New York at a special price to members of the AEA. Volume IV is announced for publication in October, 1954, and Volume V is scheduled to appear in 1955.

Ad Hoc Committee on the Status of the Profession (I. L. Sharfman, Chairman). Attention should be called to the carefully prepared report of this Committee. (See minutes and report published below.)

Ad Hoc Committee on Implementation of the Bowen Report (G. L. Bach, Chairman). See minutes.

Reports of Council Representatives. Reports of our representatives to the ACLS, SSRC, and to the NBER (published below) should be of interest to our members.

Committees Appointed During the Year

COMMITTEE ON LOCAL ARRANGEMENTS
Edward L. Cushman, *Chairman*

COMMITTEE ON ELECTIONS
Frank G. Dickinson, *Chairman*
S. Morris Livingston
James Washington Bell, Ex Officio

Ad Hoc COMMITTEE ON IMPLEMENTATION OF BOWEN REPORT
George L. Bach, *Chairman*
Robert D. Calkins
Robert A. Gordon
John K. Galbraith
Albert G. Hart
O. H. Brownlee

Ad Hoc COMMITTEE ON THE STATUS OF THE PROFESSION
I. L. Sharfman, *Chairman*
Ben W. Lewis

NOMINATING COMMITTEE
Morris A. Copeland, *Chairman*
William J. Fellner
Ewan Clague
Martin R. Gainsbrugh
Howard R. Bowen
Mary Jean Bowman

Ad Hoc COMMITTEE ON ECONOMICS IN TEACHER EDUCATION (continued from 1953)
Ben W. Lewis, *Chairman*
Archibald McIsaac
Paul J. Strayer

Standing Committees and Representatives

COMMITTEE ON HONORS AND AWARDS
Norman S. Buchanan, *Chairman* (1956)
George L. Bach (1954)
Edward S. Shaw (1954)
Fritz Machlup (1956)
Edward S. Mason (1958)
Joseph J. Spengler (1958)

COMMITTEE ON FOREIGN HONORARY MEMBERS
Wassily W. Leontief, *Chairman*
P. T. Ellsworth
Paul A. Samuelson

COMMITTEE ON RESEARCH AND PUBLICATIONS
John P. Miller, *Chairman* (1955)
Simeon E. Leland, *Acting Chairman* (1954)
George W. Stocking (1954)
John H. Williams (1955)
Joseph J. Spengler (1954)
Jacob Marschak (1955)
D. Gale Johnson (1956)
Max F. Millikan (1956)
Alexander Gerschenkron (1956)
James Washington Bell

COMMITTEE ON INTERNATIONAL CO-OPERATION
Gottfried Haberler, *Chairman*
Howard S. Ellis
Theodore W. Schultz
James Washington Bell

INTERNATIONAL ECONOMIC ASSOCIATION REPRESENTATIVES
Gottfried Haberler (1955)
Howard S. Ellis (1955)
Milton Friedman (1958)
Max F. Millikan (1958)

SOCIAL SCIENCE RESEARCH COUNCIL REPRESENTATIVES
George W. Stocking (1954)
John P. Miller (1955)
D. Gale Johnson (1956)

AMERICAN COUNCIL OF LEARNED SOCIETIES REPRESENTATIVE
Frank H. Knight (1954)

NATIONAL BUREAU OF ECONOMIC RESEARCH REPRESENTATIVE
John H. Williams (1955)

Representatives of the Association on Various Occasions

WESTERN COLLEGE FOR WOMEN, CENTENNIAL COMMENCEMENT CONVOCATION
 Paul J. Garfield
LINCOLN UNIVERSITY (PENNSYLVANIA) CENTENNIAL

Use of Mailing List

The following were granted permission to use our mailing list to send the material indicated:

UNIVERSITY OF CHICAGO PRESS: To send promotional material on six books.

COMMITTEE FOR ECONOMIC DEVELOPMENT: To send prepublication notice of papers on problems in antirecession policy, and policy statements on "Managing the Federal Debt" and "United States Tariff Policy."

UNIVERSITY OF MICHIGAN, BUREAU OF BUSINESS RESEARCH: To advertise Business Studies, Business Reports, and Business Papers series.

NATIONAL ASSOCIATION OF MANUFACTURERS: To send *Educational Aids for Colleges, Instructor's Manual for Productivity,* and research study, *Productivity—Gauge of Economic Performance.*

The Business Outlook: To send trial subscription offer.

S. Millman: To send out circular on new books in economics and some specially priced books.

THE ANTIOCH PRESS: To send material regarding the book, *Wildcat Strike,* by Alvin W. Gouldner.

INSTITUTE OF LIFE INSURANCE: To send 1953 *Life Insurance Fact Book.*

COMMERCIAL CREDIT CORPORATION: To send Clyde W. Phelps's monograph, *Financing the Instalment Purchases of the American Family.*

AMERICAN ACCOUNTING ASSOCIATION: To send invitations to members to subscribe to *The Accounting Review.*

RUTGERS UNIVERSITY PRESS: To send circular on Professor Kurihara's *Post-Keynesian Economics.*

BOYCE MORGAN & ASSOCIATES: To offer 1965 business outlook study and introductory subscription to the *Report on the Business Outlook.*

KELLEY & MILLMAN: To send out notice of a book sale.

AMERICAN INSTITUTE FOR ECONOMIC RESEARCH: To send two technical bulletins and fellowship award announcements and application blanks and announcement of *Reconstruction of Economics,* by E. C. Harwood.

Respectfully submitted,

JAMES WASHINGTON BELL, *Secretary*

REPORT OF THE TREASURER FOR THE YEAR ENDING NOVEMBER 30, 1954

The financial results for the past year are shown in the following comparative statements. The first shows financial operations and the second balance-sheet conditions for the current year compared with last year and five years ago. These tables supplement the detailed report of the Auditor, which immediately follows the Report of the Finance Committee.

Financial Operations. In the table below, showing income and expenses, we group all sources of income together as well as all items of expenditure. In the Auditor's Report, operation and publication results are separated.

COMPARATIVE RESULTS OF OPERATIONS FOR 1949, 1953, AND 1954

	11/30/49	11/30/53	11/30/54
Income			
Membership dues	$31,121	$ 41,970	$ 42,991
Subscriptions	12,254	16,491	16,838
Sales	1,863	2,524	2,440
Advertising	7,775	8,019	7,543
Directory income	1,410	—	—
Republications income	1,000	—	—
Sundry income	—	63	845
Dues and publications income	$55,423	$ 69,067	$ 70,657
Interest	$ 1,117	$ 1,435	$ 1,621
Dividends	3,170	3,588	2,962
Less custodian fees	*126*	*179*	*176*
Sales of securities (net)	48	11,636	10,727
Investments (less fees)	$ 4,209	$ 16,480	$ 15,134
Total income	$59,632	$ 85,547	$ 85,791
Expenses			
Office salaries	$11,637	$ 15,251	$ 15,491
Other administrative expenses	3,275	3,630	4 479
Annual meeting	*470*	130	*1,765*
Executive Committee	1,700	1,939	1,268
Other committee expenses	864	1,039	342
Administative and operating expenses	$17,006	$ 21,989	$ 19,814
Review printing	$20,165	$ 24,292	$ 25,031
Papers and Proceedings printing	7,845	10,936	13,933
Handbook printing	—	4,018	1,059
Editorial office (*Review*):			
Contributors	1,667	1,562	3,015
Editorial and clerical salaries	7,243	9,843	9,953
Other expenses (net)	756	78	78
Publications	$37,676	$ 50,729	$ 53,069
Total expenses	$54,682	$ 72,718	$ 72,883
Net operating income or *loss*	$ 4,950	$ 12,829	$ 12,908
Appropriations	—	—	985
Net income or deficit	$ 4,950	$ 12,829	$ 11,923

Total income from all sources amounted to $85,791 for the fiscal year 1954, which was approximately the same as for the previous year. No significant changes are noted in the two-year comparisons. By coincidence, even profits on security sales were approximately the same. Growth factors account for present magnitude when compared with five years ago, but show some flattening out, at least so far as income is concerned. However, expenses show no marked shifts except for the unusual profit figure for the 1953 annual meeting and the increases in office and printing costs. Our net income this year was again especially large. Like last year, some non-recurring income accounted for this, as well as the lack of any extraordinary expenditures.

Financial Condition. The balance-sheet figures below show comparative status of the principal assets, liabilities, appropriated and other funds, and surplus account for the current year, last year, and five years ago. The especially liquid condition is accounted for by the investment shifts referred to in the Finance Committee report. Under liabilities, "Accounts payable" represents a more normal figure than the one for the previous year, which included estimates not only for the December number of the *Review* but also the *Handbook*. Appropriations exist at this time only for the Committee on Research and Publications.

COMPARATIVE FINANCIAL CONDITION FOR 1949, 1953, AND 1954

Committee appropriations (not expended)	1,877	—	—
Life memberships	4,325	7,025	7,725
Total liabilities and funds	$30,600	$ 27,546	$ 25,234
Surplus			
Balance at beginning of period	$58,219	$ 85,417	$ 98,246
Transfers from life memberships	100	—	—
Net income or *loss* for period	4,950	12,829	11,924
Unappropriated surplus	$63,269	$ 98,246	$110,170
Total footings	$93,869	$125,792	$135,404

Net worth or surplus after deducting liabilities and appropriations from total resources amounts to $98,246, which with the net income for the year of $11,924 gives us an unappropriated surplus of $110,170. This is, in a sense, the measure of our rainy-day fund, our insurance against adverse times, our resources for new undertakings and for our continued growth. With this backlog we can continue with assurance with our present modest $6.00 per annum dues and subscriptions while our contemporaries for the most part find it necessary to raise their dues.

The accompanying table shows changes in our investment portfolio for selected dates as well as the rate of return on these investments.

Respectfully submitted,

JAMES WASHINGTON BELL, *Treasurer*

REPORT OF THE FINANCE COMMITTEE

December 23, 1954

Executive Committee,
American Economic Association,
Evanston, Illinois.

GENTLEMEN:

The following report of the investment holdings of the Association is for the fiscal year ending November 30, 1954. The exhibit shows the list of securities held by the Association at cost and at approximate market value at fiscal year-end. Changes made during the year are indicated and profit or loss on sales is shown.

During the past year, the following changes were made:

SUMMARY OF SECURITIES SOLD OR MATURED
Year Ended November 30, 1954

Shares or Par Value	Issue	Cost	Selling Price	Gain or *Loss*
	Sold			
50	Aluminum Corp. of America	$ 2,133.07	$ 3,591.73	$ 1,458.66
105	Olin Mathieson Chemical Corp.	4,713.73	5,838.70	1,124.97
50	Monsanto Chemical Co	3,120.74	4,598.68	1,477.94
100	Pillsbury Mills, Inc.	3,653.78	4,755.40	1,101.62
75	Procter & Gamble Co.	2,459.72	7,030.05	4,570.33
16/100	Gulf Oil Corp.	—	7.40	7.40
$ 3,000	U.S. Savings Series G, 2½%, 2/1/54	3,000.00	3,000.00	—
4,000	Illinois Central R R. Co., 4¾%, 8/1/66	4,026 17	4,100 00	73 83
15,000	U.S. Treasury Notes, 2⅛%, 12/1/53	15,000 00	15,000.00	—
5,000	U.S. Treasury C. of I., 2¼%, 2/15/54	5,000.00	5,000 00	—
14,000	U.S. Treasury Bonds, 3¼%, 6/15/83	13,991.25	14,918.75	927.50
12,000	U.S. Treasury C. of I., 2⅝%, 6/1/54	12,015 00	12,000.00	*15.00*
	Total	$69,113 46	$79,840.71	$10,727 25
	Bought			
50	Carrier Corp.	$ 2,990.61		
100	Olin Mathieson Chemical Corp	4,713.73		
$ 6,000	Gulf Interstate Gas Co., 6%, 12/1/54	6,240.00		
20,000	U.S. Treasury Notes, 1⅞%, 2/15/59	20,003.00		
5,000	U.S. Treasury Bonds, 2½%, 11/15/61	5,000.00		
15,000	U.S. Treasury Bonds, 2½%, 12/15/58	15,000.00		
	Total	$53,947.34		

Although but two formal meetings of the Finance Committee were held during the year, we had several informal conferences and were always within reach of each other by telephone. In May and November, we met to consider formal appraisals of our holdings and discussed investment policy at length. In general, our object was to maintain a fairly defensive position during a period of "doubtful recession" but in which stock prices were rising continuously. We started the year with the bond-to-stock ratio roughly 60:40 on cost and 50:50 on market value. Both in the spring and in the fall, we took profits on stock sales, investing the proceeds of these sales and those of maturing bonds in U.S. securities. By year-end, the 60:40 ratio of bonds to stocks was re-established on a cost basis, though the approximate market value on November 30, 1954, showed stocks worth $70,000-odd to bonds $60,000-odd.

LIST OF SECURITIES HELD BY THE ASSOCIATION

Stocks

Number of Shares of Common Stock	Issue	Cost	Approximate Market Value 11/30/54
50	Aluminum Co. of America	$ 2,133.08	$ 4,100.00
50	Carrier Corp.	2,990.61	2,825.00
200	Central and South West Corp.	2,801.69	6,075.00
100	Continental Can Co.	3,714.55	7,775.00
100	Eastern Air Lines	2,774.10	3,362.50
134	Gulf Oil Corp.	3,716.99	8,207.50
220	Household Finance Corp.	4,222.32	6,930.00
300	Houston Lighting & Power Co.	3,088.53	12,150.00
100	Kroger Co.	1,851.74	4,775.00
60	Peoples Gas Light & Coke Co.	7,466.15	9,300.00
110	Socony Vacuum Oil Co.	3,322.44	5,266.25
		$38,082.20	$ 70,766.25

Bonds

Par Amount	Issue	Cost	Approximate Market Value 11/30/54
$ 6,000	Gulf Interstate Gas Co., 6%, Interim Notes, due 12/1/54	$ 6,240.00	$ 6,300.00
20,000	U.S. Treasury Notes, 1⅝%, Series "A-1959," due 2/15/59	20,003.00	19,931.25
5,000	U.S. Treasury Bonds, 2½%, due 11/15/61	5,000.00	5,042.19
8,000	U.S. Treasury Bonds, 2¾%, Series "B," due 1975/80	8,000.00	7,985.00
7,000	U.S. Treasury Bonds, 2½%, due 12/15/72–67	7,275.63	6,927.81
15,000	U.S. Treasury Bonds, 2½%, due 12/15/58	15,000.00	15,328.13
	Bonds	$61,518.63	$ 61,514.38
	Stocks	38,082.20	70,766.25
	Total	$99,600.83	$132,280.63

The above table shows that securities costing $69,113 were sold at $79,840, making a profit of $10,727. From the proceeds of about $80,000, we invested approximately $54,000, representing some shifts in stocks but mostly in government securities. The $20,000 shown as receivables on November 30 were invested a few days later in government securities, which means in final analysis that some $6,000 were taken out of the fund.

The exhibit accompanying the Treasurer's Report shows our investment holdings and the rate of return on cost over a period of years. The rate of return for the past year averaged nearly 5 per cent.

Respectfully submitted,

ROY C. OSGOOD, *Chairman*
C. WELLS FARNHAM
JAMES WASHINGTON BELL

REPORT OF THE AUDITOR

December 20, 1954

Executive Committee
American Economic Association
Evanston, Illinois

DEAR SIRS:

In accordance with instructions we have examined the accounts and related records of the American Economic Association for the year ended November 30, 1954, and now submit our report thereon together with the following exhibits:

Statement of Financial Position— November 30, 1954	Exhibit 1
Statement of Income and Expense for Year Ended November 30, 1954	Exhibit 2

Results from Operations

Net income for the year ended November 30, 1954, was $11,924 compared with net income of $12,829 for the year ended November 30, 1953, as shown in the following summary:

Particulars	Year Ended November 30 1953	1954	Increase *Decrease*
Income:			
Dues	$41,970	$42,992	$1,022
Interest and dividends (net)	4,844	4,406	*438*
Profit on sales of securities (net)	11,636	10,727	*909*
Miscellaneous income	63	845	782
Total income	$58,513	$58,970	$ 457
Expense:			
Publication expense	$50,729	$53,068	$2,339
Less—Publication income	27,034	26,821	*213*
Net publication expense	$23,695	$26,247	$2,552
Administrative and other operating expenses	21,989	19,814	*2,175*
Total expense	$45,684	$46,061	$ 377
	$12,829	$12,909	$ 80
Less—Appropriation	—	985	985
Net Income	$12,829	$11,924	$ *905*

The increase in dues reflects the increase in membership during the year under review, as reported by the Secretary:

Classification	Number of Members at November 30 1953	1954
Regular	6,682	6,866
Junior	409	363
Family	121	123
Life	62	69
Honorary	21	19
Complimentary	40	46
Total	7,335	7,486

Interest on bonds owned was accounted for in accordance with stated rates; dividends received on stocks were compared with amounts reported in published records of dividends paid.

Net publication expense, as shown in the following summary, amounted to $26,247 for the current year compared with $23,695 for the preceding year:

Particulars	Year Ended November 30 1953	1954	Budgetary Estimates for Year 1954
Expenses:			
Printing of—			
Review	$24,292	$25,031	$24,700
Handbook	4,018	1,059	
Proceedings	10,936	13,933	
Editor's honorarium	3,500	3,500	3,500
Payments to contributors	1,562	3,015	2,500
Editorial clerical salaries	6,343	6,452	6,550
Editorial supplies and expenses	493	713	600
Sundry publication expenses	415	635	
Total expenses	$50,729	$53,068	
Less—Income:			
Subscriptions, other than members	$16,491	$16,838	
Sales of copies	2,524	2,440	
Advertising	8,019	7,543	
Total income	$27,034	$26,821	
Net publication expense	$23,695	$26,247	

There was an increase of $2,552 in net publication expense (from $23,695 to $26,247) consisting of the following:

Increase in subscriptions	$ 347
Decrease in copy sales	84
Decrease in advertising	476
Increase in expenses (net)	2,339
Net increase	$2,552

Billings for the December, 1954, issue of the *Review* and reprints had not been made by the publishers at the time of our examination. The publishers estimated the *Review* printing to cost $6,550 and the reprints $105 which amounts are included in the foregoing tabulation.

Financial Position

Condensed statements of financial position of the Association at November 30, 1953, and 1954 are compared below:

Assets	November 30 1953	1954	Increase *Decrease*
Cash on deposit and on hand	$ 4,568	$ 12,041	$ 7,473
Receivables (net)	3,671	21,479	17,808
Prepaid expenses	969	644	*325*
Furniture and fixtures (net)	1,817	1,640	*177*
Investments at cost—			
Bonds	68,308	61,519	*6,789*
Stocks	46,459	38,082	*8,377*
	$125,792	$135,405	$ 9,613
Liabilities, Funds and Surplus			
Accounts payable	$ 10,590	$ 7,467	$ *3,123*
Deferred income	8,062	8,597	535
Sundry fund		10	10
Membership extension fund	609	491	*118*
Fund for Committee on Research and Publications	315	945	630
Committee on Public Issues	945		*945*
Life memberships	7,025	7,725	700
Surplus—			
Balance at beginning of year	85,417	98,246	12,829
Net income for year	12,829	11,924	*905*
	$125,792	$135,405	$ 9,613

Cash on deposit was satisfactorily reconciled with balances confirmed directly to us by the depositories.

The receivables of the Association were not confirmed by correspondence with debtors. Based upon the Association's past experience the reserve for doubtful accounts appears to be adequate to cover normal losses.

Changes in the investment account were verified by the examination of brokers invoices and other supporting data. Securities held at November 30, 1954, were confirmed directly to us by the State Bank and Trust Company of Evanston, Illinois, custodian for the Association.

Insofar as we were able to ascertain, all liabilities of the Association at November 30, 1954, are reflected in the accompanying statement of financial position and the Secretary has represented to us that to the best of his knowledge all liabilities are disclosed.

A summary of the transactions in the various funds is presented hereunder:

Particulars	Membership Extension Fund	Sundry Fund	Public Issues	Committee on Research and Publications
Balance November 30, 1953	$608.96	$	$944 91	$314.56
Changes during year—				
Appropriations				985.44
Received		37.76		
Expended	*118.20*	*28.06*	*160.25*	*355.26*
Transferred to miscellaneous income			*784.66*	
Balance November 30, 1954	$490.76	$ 9.70	$	$944.74

We were advised that the Committee on Public Issues was discontinued. The unexpended balance was transferred to miscellaneous income.

We express our appreciation of the courtesies and cooperation extended to our representatives during the course of the examination.

Very truly yours,

DAVID HIMMELBLAU & CO.
Certified Public Accountants

AUDITOR'S OPINION

Executive Committee
American Economic Association.

In our opinion, the accompanying financial statements present fairly the financial position of American Economic Association at November 30, 1954 and the results of its operations for the year ended that date, in conformity with generally accepted accounting principles applied on a basis consistent with that of the preceding year.

Our examination was made in accordance with generally accepted auditing standards and included such tests of the accounting records and other auditing procedures as we considered necessary in the circumstances.

REPORT OF THE MANAGING EDITOR FOR THE YEAR ENDING DECEMBER, 1954

The editor of a professional journal is seldom content. Either the flow of good manuscripts is not as heavy as he would like or it is more than adequate, with the result that he is unable to find room for all of the papers worthy of publication. It is the latter situation that has confronted the Editorial Board of the *Review* this past year. Although the total number of manuscripts submitted has not increased as compared with 1953, the number of articles as distinct from communications has risen from 122 to 160. Furthermore, it is the general impression of members of the Editorial Board that the quality of the papers offered for publication has been noticeably better than in recent years. At the same time, the percentage of articles accepted has of necessity dropped to a very low 12.5 per cent, even though the space allocated to them was increased substantially. Many of the articles that could not be accepted have, however, found other publication outlets. Table 1 gives comparative figures with regard to manuscripts submitted for the past six years.

TABLE 1

MANUSCRIPTS SUBMITTED, 1949-54

	1954	1953	1952	1951	1950	1949
Manuscripts received	231	234	190	222	197	200
Articles...... ..	160	122	133	157	156	144
Communications	71	112	57	65	41	56
Percentage of articles accepted	12.5	15	21	19	19	20

As the table also reveals, the number of communications submitted this past year was much lower than in 1953. This, however, is not surprising, as the 1953 year was abnormally high, owing to the fact that there were included in the 1952 volume seven articles that turned out to be highly controversial. The flow of communications returned to something like a normal level this past year.

Table 2 provides a summary of the break-down of the volume as between articles, communications, book reviews, etc. Since the proportion of the volume devoted to articles was increased in response to the increase in the number of acceptable manuscripts submitted, space devoted to communications correspondingly contracted; and there was some reduction in the space devoted to book reviews (without, however, a corresponding reduction in the number of books reviewed). The other departments of the *Review* changed comparatively little.

We have continued the policy of slightly favoring articles that have some empirical basis. Of the thirty leading articles in the 1954 volume, I believe it

would be fair to say that fourteen were based on empirical, or at least factual, research, while thirteen were essentially theoretical, and three review articles. With regard to subject-matter fields, there was the usual concentration in general economic theory—seven articles and three communications. This past year, however, there was also an unusually heavy concentration in the international field—eight articles and two communications. The remaining papers were rather widely distributed. Table 3 summarizes the subject-matter distribution for the thirty articles and seventeen communications.

The problem of book reviews continues to be troublesome. As in the past few years, many books that should have been given at least a short review notice have had to be passed over. I am told time and again by members of the Association that they find the book review section particularly useful, and that they would like to see more nearly complete coverage of the new books. Yet I do not believe that this should be done at the expense of the space devoted to

articles and communications; and the other departments have been reduced to about their minimum length if they are still to be useful. I have tried out this past year on a very limited scale the device of short summary notes prepared by graduate students in the case of less important books; but I am not satisfied that the solution lies in this direction. I have also reduced the average length of the book reviews accepted, by insisting on quite short reviews in some cases.

Another difficulty with the book review section has been the rather limited extent to which reviews of foreign books have been included. This is partly due to lack of space, but to a greater extent to the difficulty of learning about the books published abroad that are worthy of review. In order to begin to meet this problem, I have been authorized by the Executive Committee of the Association to appoint a number of foreign correspondents who will advise me from time to time about important books published in their respective countries, and who will, I hope, serve the *Review* in other ways as well. Thus far the following correspondents have been appointed, and have been assisting me this past year:

Alexandre Kafka (Brazil) — Victor L. Urquidi (Mexico)
Jean-Marcel Jeanneney (France) — P. J. Verdoorn (Netherlands)
Erich Schneider (Germany) — Erik Lindahl (Sweden)
Giovanni Demaria (Italy)

The increase in the number of reviews of foreign books that may be expected to result from this program will of course put further pressure on the available space for reviews; but some reallocation of space in favor of the work of the economists of other lands is surely desirable. It may, however, also be desirable to consider whether the Association can afford to increase the size of the *Review* about thirty pages per volume—the additional space to be devoted to reviews of foreign books.

Table 4 presents the actual expenditures in 1954 in comparison with the estimated budget and with actual expenditures in 1953. Partly because of the increase from 10,900 to 11,000 in the number of copies printed, our costs for printing and mailing are about $700 higher than the budgeted amount, and about $1,000 higher than last year. The other items are quite close to their budgeted amounts for the year. Because of the larger number of articles published, the payments to contributors were substantially higher in 1954 than in

TABLE 4

ACTUAL AND BUDGETED EXPENDITURES

	Budget 1954	Actual 1954	Actual 1953
Printing and mailing	$24,700	$25,436.52*	$24,365.57†

Respectfully submitted,

BERNARD F. HALEY, *Managing Editor*

REPORT OF THE COMMITTEE ON RESEARCH AND PUBLICATIONS

The Committee on Research and Publications presents herewith a report of progress and achievements for the current year:

1. The translation of Walras, *Elements d'Economie Politique Pure,* by William Jaffé, sponsored by the American Economic Association and the Royal Economic Society, has appeared in published form. The volume has been well received. Sales are going well. A number of reviews also appeared; more are scheduled for publication.

2. The preliminary draft of *Readings on Fiscal Policy,* under the editorship of Arthur Smithies and J. K. Butters, has been prepared and the final draft of the manuscript is being completed. The volume should appear in 1955.

3. An article on "Bibliographies in Economics" for publication in the *Review* is in preparation by Donald Irwin. This project was approved by the Executive Committee, April 2, 1954. It will be useful not only to economists but also to reference librarians.

4. The preparation of a volume of readings on industrial organization was put on the agenda for the next meeting of the Committee on Research and Publications. George Stocking agreed to present a preliminary report on the articles available and to suggest a possible list of readings for publication. The feasibility of this project can then be determined.

5. Consideration was also given to the possibility of publishing a book of readings on economic growth. Max Millikan agreed to prepare a list of possible items for such a volume for the next meeting of the Committee. On the basis of this report the scope and emphasis of the volume could be determined. It was suggested that some of the readings be devoted to the problems of underdeveloped countries. Historical materials were also to be given weight.

The Committee on Research and Publications also considered various proposals for the translation of foreign works, but no action was taken. The Committee continued to believe that translations of the works of Pareto should have highest priority at this time. Gale Johnson agreed to present a report on the status of Pareto translations at the next meeting of the Committee.

The major business before the Committee was the proposal to prepare a cumulative index of the *American Economic Review* and the *Papers and Proceedings* of the American Economic Association. The details of a basic plan for the index and cost estimates therefore were presented by Bernard Haley, who had constructed a sample index based upon four regular numbers of the *Review* (December, 1953, to September, 1954) and the May, 1954, *Papers and Proceedings.* After considerable discussion it was decided to recommend to the Executive Committee that it authorize the compilation and publication of a cumulative classified index of the *American Economic Review* and the *Papers and Proceedings* of the American Economic Association for the period since 1911, the indexing plan to be roughly as follows: (1) index to cover Volume I to XLIV (or XLV depending upon date of completion of the index) of the

Review and *Papers and Proceedings;* (2) the index to follow a subject-and-author classification of articles, communications, and papers in the *Review* and *Papers and Proceedings* from 1911 to date; index of book reviews, excluding index of reviewers, to be included from 1930 to date. The classification of subject matter should be the groups or fields (eighteen classes) currently used in the *Review.*

It was recommended that 5,000 copies of the index be published and offered for sale to members of the Association. The Committee was of the opinion that the index could be sold for $1.00 per copy. The volume would probably exceed 400 pages in length. Preliminary estimates of cost ran from $7,500 to $8,000.

The Committee on Research and Publications also considered an alternative proposal to sponsor the construction of an index of the seven or eight leading English and American periodicals in economics for the last ten or fifteen years. A number of those consulted felt that such an index would be of greater value to the profession than an index of the publications of the American Economic Association alone. The cost of this project would be $10,000 to $12,000, depending on the coverage and the details of the indexing plan. The Committee felt that such a project would require foundation assistance.

Respectfully submitted,

SIMEON E. LELAND, *Acting Chairman*

REPORT OF THE EXPLORATORY COMMITTEE ON THE STATUS OF THE PROFESSION

A year ago Professor Clair Wilcox reported, as chairman, for the *Ad Hoc* Committee on Freedom of Teaching, Research, and Publication in Economics. (See *Papers and Proceedings,* May, 1954, pages 733-737.) This report analyzed the situation carefully and at some length. It first surveyed the Executive Committee's active concern for the preservation of freedom in these spheres—through its resolution of 1947 affirming "the free and untrammeled right" of college and university teachers to select textbooks and related materials in their teaching and research; through the establishment in 1948 of the past-presidents' Committee on Academic Freedom of which Professor Frederick C. Mills was chairman; and through the constitution in April, 1952, upon the discharge at its own request of the Mills committee, of the *ad hoc* committee for which Professor Wilcox reported in December, 1953. It also focused attention upon the major issues involved in this continuing concern of recent years.

The questions raised in the two committees thus established—and particularly in the discussions of the Executive Committee throughout the period—were stated and answered by the Wilcox committee as follows:

> 1. Should the Association undertake to prepare and publicize a declaration of principles of academic freedom for economists? *We think not.* [No italics in original.]
>
> 2. Should the Association undertake to investigate and report upon specific cases involving infringement of the academic freedom of economists? *Again, we think not.* [No italics in original.]
>
> 3. What other action, if any, should the Association take with respect to freedom of teaching, research, and publication?
>
> . . . .
>
> *We believe a report should be prepared each year, and published in the annual volume of* Papers and Proceedings, *on the status of the profession, including information on current attacks on freedom and apparent threats to freedom, on the conditions that promote freedom and on those that discourage it. We therefore recommend that the Executive Committee provide for the creation of a standing committee on the status of the profession to prepare such a report.* [No italics in original.]

In light of this recommendation, President Kuznets set up the present Committee, to explore "the need and scope of activity" for a standing committee on the status of the profession. "Before a standing committee is established," he wrote, "we must be sure that there is a useful field of activity to be pursued; and the possibility of pursuing it within the usual limitations of what any committee can reasonably be expected to do."

Some time after this exploratory committee was created, President Kuznets submitted to it a communication which he had received from Dr. Horace B. Davis, of the University of Kansas City, who had been discharged from his position as associate professor, of economics because he refused to answer questions concerning his political views or affiliations. Shortly thereafter, President Kuznets also had submitted to the Committee a letter from a group of French economists and one from a group of Austrian economists, protesting

the prosecution of Paul M. Sweezy for contempt of court, as a result of his refusal to answer certain questions in a New Hampshire investigation of subversive activities, as well as copies of correspondence between Dr. Sweezy and the Managing Editor of the *American Economic Review* with respect to the publication of a notice of this incident. Dr. Davis asserted "that the American Economic Association cannot afford to disregard this affront to one of its members and should take some action." Dr. Sweezy merely requested that the following item be published in the "Notes" section of the *Review:* "Paul M. Sweezy, formerly of the Harvard Economics Department, has been sentenced to jail in New Hampshire for refusing to answer questions, in a state investigation of subversion, regarding a lecture on the subject of socialism which he delivered in a course at the University of New Hampshire." In each instance President Kuznets requested the exploratory committee to "take a look" at the situation and advise him as to "what, if anything, should be done about it."

We will first deal with these specific cases.

With respect to the Davis case, the Committee advised President Kuznets that "there is nothing the American Economic Association can do or should do in the circumstances of this situation." Even if there were an appropriate sphere of activity for the Association in connection with individual discharges involving alleged infringement upon academic freedom and tenure, it seems probable that this would not be such a case, either for investigation or for action. From the material Dr. Davis has himself submitted it appears that he was discharged because of his unwillingness to co-operate with the university authorities and not because of his political views or his reliance upon the Fifth Amendment. In his own words, he was fired "for refusing to answer, not the Congressional Committee, but the Board of Trustees." In the judgment of this Committee, it is altogether reasonable and proper for a university, through its appropriate officers or agencies, to insist that those who constitute its faculty shall deal with it frankly and make available to it all facts and circumstances that may bear upon their status in the academic community. It must be recognized that reciprocal responsibilities govern the situation, and not merely a one-sided obligation unquestioningly to protect the staff member under attack. Only on such a basis can a university operate intelligently and effectively in safeguarding the intellectual freedom we all cherish. It appears that the American Association of University Professors sought to prevent the discharge of Dr. Davis, though without success; that the investigation of the case is being continued; and that Dr. Davis is "preparing a legal test of the University's action." While the final outcome will of course be of interest to economists, there appears to be no adequate ground for special concern on the part of the Association.

The Sweezy case is of a different character. As yet we have made no recommendation to President Kuznets and nothing has been requested of the Association by Dr. Sweezy other than to serve, through the *Review,* as a channel of communication with his colleagues in the profession concerning this experience.

When the incident was brought to the attention of the exploratory commit-

tee, we asked Dr. Sweezy for "the full story," particularly insofar as it might be available in published form. He sent us the August, 1954, issue of *Monthly Review*, which contains an article by Leo Huberman, coeditor of the journal with Sweezy, entitled, "The Daggett-Sweezy Case."

It appears from this account that at a closed hearing, on January 8, 1954, Sweezy answered questions, in an investigation by the State Attorney General of "subversive activities" and "subversive persons" within the state of New Hampshire, to the effect that he "was a Marxist and a socialist," that he "had never been a member of the Communist Party," that he "had never attended any meetings of the Communist Party anywhere," that he "did not, of his own personal knowledge, know any members of the Communist Party in the state of New Hampshire," and that he "did not now advocate, nor had he ever advocated, the overthrow of constitutional government by force and violence"; but that he refused to answer questions "concerning the Progressive Party or people alleged to be connected with it." A second hearing, also closed, was held on June 3, 1954. At this hearing Sweezy again refused to answer questions "concerning the Progressive Party and alleged members thereof"; and he also refused to answer questions "concerning a lecture on the subject of 'Socialism' which he had given at the University of New Hampshire on March 22, 1954."[1] He stated that neither in that lecture nor in any other lecture anywhere did he advocate the overthrow of constitutional government by force and violence; but he declined to answer any further questions concerning the lecture, on the grounds that such questions were beyond the scope of the inquiry authorized by the legislative resolution of 1953 "directing the Attorney General to inquire into violations of the Subversive Activities Act of 1951," and that they constituted "an invasion of constitutional rights of free speech guaranteed by the First Amendment." On June 28, on petition of the Attorney General, a court hearing was held, to compel answers to the disputed questions or to subject the recalcitrant witnesses to citation for contempt of court—"an offense for which the penalty in New Hampshire is normally jail until such time as the defendant choses to purge himself of contempt, which in this case would mean answering the questions." On June 30 the court upheld the position of the Attorney General. Sweezy was found to be in contempt and sentenced to jail; but over the objections of the Attorney General he was admitted to $1,000 bail, pending an appeal of the case to the Supreme Court of New Hampshire.[2]

While the article upon which the above account is based was "intended as a recital of facts and nothing more," and while it may doubtless be deemed

[1] "This was the third year," it was reported, "in which Sweezy had given the lecture on socialism," at the invitation in each instance of Dr. Gwynne Harris Daggett, associate professor of English and a member of the staff of the Humanities Course offered at the University. Professor Daggett had also been questioned at two closed hearings, and he likewise refused to provide information concerning the Progressive Party or the lecture on socialism.

[2] In the Daggett case, there was not only the threat of punishment for contempt of court, but the likelihood of discharge from his teaching post at the University. Accordingly, upon advice of counsel and numerous friends, and after receiving assurance from Sweezy that "the fight would be continued" and that "the case would be carried to the highest courts so that the important constitutional questions involved could be decided," Professor Daggett answered the disputed questions and the case against him was dismissed.

to be accurate and reliable, it is none the less an ex parte statement. Hence a full and properly-balanced knowledge of the facts must await further developments. Sweezy has promised to send to this Committee "printed copies of the record on which the appeal is being taken, and these will include not only the court proceedings but also the transcript of the hearings which went before." This material, together with such decisions of the appellate courts as may follow, will not only disclose all the relevant facts, but should throw revealing light upon the merits of the controversy.

As already noted, however, all that Sweezy requested was the publication of a brief notice of the matter in the *Review*. "I have many friends and acquaintances in the American Economic Association who are perhaps not likely to hear of this incident otherwise," he wrote to Professor Haley, "and I would appreciate your affording me this opportunity of informing them." Professor Haley felt that the problem ought to be attacked, not by broadening the "Notes" section of the *Review*, but through handling by the standing committee on the status of the profession, the creation of which was recommended in the report of the Wilcox committee. Sweezy replied that he did not mean to suggest that the inclusion of such items in the "Notes" "would be an adequate method of dealing with current threats to academic freedom so far as they affect the economics profession"; but he insisted that there remained, in any event, "a plain problem of communication" concerning attacks on economists' civil liberties for which the *Review* obviously afforded the best medium. In these circumstances he took the liberty of suggesting that the question of the publication of such notices be taken up with the Board of Editors as a whole or with such other body as is ultimately responsible for the policy of the *Review*. While Professor Haley readily expressed approval of this suggestion and promised also to bring the matter to the attention of the Executive Committee as an important problem in Association policy, he stated explicitly and incisively some of the difficulties involved in the Sweezy proposal, particularly as they bear upon implied expressions of judgment as to the merits of such controversies.[3] Thereupon Sweezy suggested a process of "continuous cooperation" between the *Review* and the recommended standing committee which would be calculated to eliminate the difficulties envisioned by the Man-

[3] Asserting that he believed it to be "the position of the Association officers that they are not ready or equipped to take a position on *individual* cases involving academic freedom or civil liberties," he continued: "I am sure that you believe that your proposal does not involve the Association in this way, since you regard it as simply designed to meet a 'plain problem of communication' through 'dissemination of factual information' But is it as simple as this? Do I take the responsibility for publishing every item of this sort involving an economist, in the form written by the complainant, describing from his point of view threats or actions that have the effect in his judgment of impairing his academic freedom or civil liberties? If so, do I attach to these items as published an editorial note disclaiming all responsibility for their factual accuracy? Do I stand ready to provide space also for replies and comments of others who cite different facts or place a different interpretation upon the facts from that given by the complainant? Or do I, or does some other agency of the Association, first conduct some sort of investigation of the accuracy of the facts cited in the complaint? If so, what facilities does the Association have for conducting such factual investigations? And is it not pertinent to point out that the Association would be assuming the responsibilities of the American Association of University Professors?"

aging Editor. He specified that civil liberties cases in which a member of the profession is concerned would be reported to the committee; and the committee would be charged with verifying the facts "and making a brief factual report in the next issue of the *Review* if it concluded that substantial issues were involved." The purpose of such a procedure, wrote Sweezy, "would not be to dispose of civil liberties cases nor to displace the AAUP, but simply to inform the profession"; and with this suggestion Professor Haley found himself in complete agreement.[4]

Since we have been constituted as an exploratory body rather than as an actions committee, the primary significance of these cases lies in their bearing upon the issues presented to us by the report of the Wilcox committee. In the judgment of this exploratory committee, they tend to confirm the soundness and wisdom of the Wilcox recommendations; and the same conclusions were reached by this Committee independently of these specific cases.

Negatively, the Wilcox committee found it inadvisable for the Association either to formulate any general declaration of principles concerning academic freedom of economists or to investigate specific cases of alleged infringement upon the academic freedom of economists. In reaching this conclusion, convincingly supported in its report, the Committee was confirming a like judgment by the earlier Mills committee on academic freedom. In its report to the Executive Committee dated March 22, 1952, it declared "that a policy calling for the active investigation and enforcement of principles of academic freedom is inappropriate and undesirable." In developing the reasons for this opinion, the Mills committee not only called attention to the "exhaustive on-the-ground investigations" of all cases and the "very considerable costs, in money and time," that would be involved, but, like the Wilcox committee, placed emphasis upon the fact that the handling of these matters is the special function of the AAUP. In its own words: "There exists a body created for the central purpose of defending academic freedom. Capable men have worked for many years through the AAUP on the complicated problems of academic freedom. A body of experience has been built up and a national reputation won by the AAUP in this field. Confusion, overlapping of effort, and waste could be expected if each professional society were to follow an independent program in

[4] On the same day on which Sweezy made his final suggestion to Professor Haley, he wrote as follows to the chairman of this exploratory committee: "It occurs to me that your committee may have some trouble connecting this case with the economics profession in a definite enough way to warrant your taking account of it. That would not surprise me, and I am not quite sure what my own answer would be. I sent the small news item, which you saw, to the editor of the *American Economic Review* because I wanted to find some method of communicating with the many people in the profession whom I know and many of whom I think would be interested in the case. I know from experience that this is not easy, some of my closest friends at Harvard when I was there having only just heard of the whole matter and that rather by chance. But whether the fact that a member of the profession—and I trust I qualify as such even though I am not now teaching at a University—is a victim in a civil liberties case which certainly involves academic freedom but is not immediately related to his status as an economist, whether this constitutes ground for concern on the part of the profession as such, I really do not know. I should hope so, if only because I think it would be better for everyone to overextend his interests in civil liberties rather than the reverse, but I am quite aware that my views in matters of this sort are likely to be different from those of others in the profession."

enforcing and protecting academic freedom." The present Committee is unequivocally of the same mind. As its chairman wrote President Kuznets on September 27 in advising him concerning the Davis case: "While I may be anticipating my committee's report of next December, I am constrained to say unhesitatingly that . . . the type of problem involved in the present-day drive against so-called subversives in our educational institutions concerns the academic community as a whole rather than particular disciplines, and that there is no distinctive sphere of activity for our Association as such in these controversies. The American Association of University Professors appears . . . to be the appropriate agency for safeguarding intellectual freedom in our colleges and universities; and if the AAUP is not proving to be an effective instrument for this purpose, it behooves university personnel as individuals, as well as the various professional organizations or learned societies with which they are affiliated, to seek to strengthen this over-all group or to establish a new and adequate over-all group in its place. It would be most unfortunate if the highly controversial concept of academic freedom as it emerges in the contemporary scene were to be defined and applied separately and independently by each of the many academic disciplines which might become involved. It is of the utmost importance that such a situation be avoided."[5]

But the Wilcox committee, while recognizing that the AAUP, with its more than 40,000 members and sizable annual budget, "still retains a substantial measure of prestige," declared it to be "lacking in vigor and effectiveness," and concluded that "the most important step that could be taken to preserve freedom of teaching, research, and publication would be the reinvigoration of the AAUP." The independent confirmation or denial of these judgments would require a more extended process of investigation than this exploratory committee could feasibly undertake. Its chairman did visit the Washington office and conferred with the general secretary. The impression carried away is that the AAUP's inadequate performance is due in no small measure, aside from temporary emergency considerations, to insufficient resources and an absence of sufficient activity on the part of the membership. This means too small a professional staff of full-time workers and too few part-time lay volunteers, in view of the constantly increasing burden of tasks that must be handled. It should be kept in mind, furthermore, that in the present climate of opinion and the prevailing investigatory techniques with respect to so-called "security risks," college and university personnel tend to become involved, not so much in the traditional distinctively-academic disputes, as in what amount in essence to general civil-liberty controversies; and that much of the AAUP's performance assumes the unspectacular form of more or less successful mediatory efforts. In any event, whatever the present shortcomings of the AAUP—and its Committee on Organization and Policy is working assiduously to find ways

[5] With reference to the specific grievance, the chairman wrote: "In the case of Dr. Davis of the University of Kansas City it appears to be entirely clear from his own account that the discharge was not grounded in the fact that he was an economist. There is every reason to believe that the same result would have followed if he had been an astronomer or an archaeologist. The fact that he is an economist, and a member of the AEA, is purely coincidental." In due course this communication to President Kuznets was approved by the other member of the exploratory committee.

and means of improving the situation—such shortcomings would be likely to be much more pronounced in the case of separate professional organizations or learned societies acting independently for the various academic disciplines. For investigations on the merits and for the exertion of pressures designed to safeguard freedom in teaching, research, and publication, we must continue to avail ourselves of the forty-year experience of AAUP, which came into being with the central objective of preserving and promoting academic freedom and whose principles and procedures in this sphere have received widespread approval.[6]

The affirmative recommendation of the Wilcox committee likewise merits full approval. While the tasks of formulating principles and procedures and applying them in individual cases should appropriately continue to be reserved to the AAUP, a broad and important interest none the less remains for the American Economic Association, as for other organizations of academic disciplines, in being kept informed concerning the aggregate experience of the membership of the profession and concerning the developments which tend to hamper or advance its contributions to knowledge, and insight, and fruitful scholarship. In the extraordinary circumstances of the contemporary scene, the information to be provided will tend to center upon "current attacks on freedom and apparent threats to freedom," as well as upon "the conditions that promote freedom and those that discourage it"; but the more general position of the profession is also a matter of legitimate concern for the Association. Hence the Wilcox group recommended that a standing committee on the status of the profession be established. The function of the committee, as a minimum, would be to prepare an annual report dealing with the aforementioned matters, to be published in the regular volume of *Papers and Proceedings* issued each year. Such a report should properly embrace not only developments with respect to college and university personnel but those concerning all members of the profession, whether they hold academic or governmental or business appointments or function independently as individuals. There can be no question, of course, that the Sweezy incident merits inclusion in such a report. But the usefulness of this provision of information would be greatly enhanced if accurate factual knowledge of relevant developments of substantial significance were made available on a more current basis. Hence the plan evolved by Dr. Sweezy and Professor Haley for quarterly publication in the *Review* of statements of facts verified by the standing committee concerning alleged infringements upon the academic freedom or civil liberties of economists fully approves

[6] See AAUP *Bulletin*, Spring, 1954 (Vol. 40, No. 1), which contains not only the 1940 and 1925 Statements of Principles, but the original 1915 Declaration of Principles of Academic Freedom and Tenure. It is interesting to note that at the organizational meeting of AAUP on January 1 and 2, 1915, "it was *voted* that the Association form a Committee on Academic Freedom and Academic Tenure, which should include members of a joint Committee on Academic Freedom and Tenure of the American Economic Association, the American Political Science Association, and the American Sociological Society, which had been constituted in 1913 to study and report on problems of academic freedom and tenure in teaching and research in economics, political science, and sociology." Three past presidents of the American Economic Association—Edwin R. A. Seligman, Richard T. Ely, and Frank A. Fetter—were members of this Committee which drew up the original Declaration of Principles and Professor Seligman was Chairman of the Committee.

itself to this exploratory committee. These quarterly reports would provide the principal materials for the annual surveys; and since the AAUP would constitute the primary source of the information utilized in these reports, the activities of the standing committee would provide a potential base for more general co-operation between the AAUP and the American Economic Association. The standing committee might well serve in an advisory capacity to AAUP investigating committees in such matters as involve the special competence of economists, and it might also exercise leadership in obtaining, when likely to prove helpful, the formal support of the Executive Committee for crucial AAUP actions. Finally, on the basis of its accumulated and continuing experience, it might submit recommendations to the Executive Committee from time to time for altering or expanding its own functions and responsibilities, as well as those of the Association as a whole, in relation to the AAUP and to the rights, duties, and opportunities of economists.

In summary, then, and in terms of the frame of reference established for us by President Kuznets, we find a clear need for the recommended standing committee; and we conclude that its scope of activity should be limited, at least for the time being, primarily to the provision of factual quarterly, if necessary, and annual reports, to be published respectively in the *Review* and in the *Paper and Proceedings*, concerning alleged infringements upon the academic freedom or civil liberties of economists, but to be supplemented by such general observations and recommendations concerning the status of the profession and the Association's relation thereto as might promise to be fruitful.

The thinking of the exploratory committee has been developed into a rather extensive report, in the hope of continuing the stimulus of the general membership of the Association provided in this sphere by the excellent report of the Wilcox committee. Toward the same end, we suggest that for the next annual meeting of the Association, the standing committee on the status of the profession, if established, might very usefully arrange a session on freedom of teaching, research, and publication in economics, so that the membership may be afforded an opportunity to participate actively in a discussion of these crucial problems of academic freedom and civil liberties.

I. L. Sharfman, *Chairman*
Ben W. Lewis

REPORT OF THE *AD HOC* COMMITTEE ON ECONOMICS IN TEACHER EDUCATION

This Committee has had as its special concern the activities (and the problems that have prompted the activities) of the Commission on Economics in Teacher Education. Of necessity, however, the interest of the Committee has extended to other sectors in the broad field of economic education. Members of the Committee, as individuals, have participated in the work of the Joint Council on Economic Education (the parent body with which the Commission on Economics in Teacher Education is affiliated), with the Business Education Committee of the Committee for Economic Development, and in several other activities within this general area.

One significant fact has emerged clearly from our several experiences: economics is "on the march" in the schools, in business, and in adult and general education. In this connection it is getting a measure of attention from professional economists, but we believe that most members of the profession are only slightly aware of the force and character of the movement. There is great strength in the movement and, at least so far as sheer volume is concerned, it will make substantial strides in the years immediately ahead, either with or without the support of our profession. On the score of direction or quality, however, there is reason for uncertainty and even misgiving. Herein, it seems to us, as well as to many who have indicated their concern to us, lies an opportunity for and the responsibility of professional economists. If the level of economic understanding among the American people that results from this movement is lower than we believe to be good and if in the meantime we sit by, indifferent or uncertain and inactive, we have only ourselves to blame.

Members of this Committee are aware of the continuing interest of a sizable segment of the profession in the problems of teaching economics at the college level. We are aware of sporadic professional interest in economics in adult and general education and in the schools. And we are aware, also, of a growing "feeling" that in some way and in some degree the American Economic Association should play a more active and positive role in stimulating and helping to focus the interest and activities of its members in this entire area of economic education. There is diversity of opinion as to the precise part which the Association should undertake, but the belief is substantial and growing that the Association is not now carrying its full responsibility in this area. This matter needs exploration looking toward action.

In light of the foregoing, this Committee recommends that:

1. This Committee be continued as an *ad hoc* committee under the name of the Committee on Economic Education.

2. The Committee be instructed to explore and to bring findings and recommendations to the Executive Committee, if possible at its spring meeting, 1955, on the need for and the character of action properly to be taken by the As-

sociation to stimulate and to help to focus the interest of its members in the area of economic education; that is, the teaching of economics at the college level and in the schools (including teacher training), economics in business education (including "business" in economic education), and economics in adult and general education.

BEN W. LEWIS, *Chairman*
ARCHIBALD M. MCISAAC
PAUL J. STRAYER

REPORT OF OUR REPRESENTATIVE TO THE INTERNATIONAL ECONOMIC ASSOCIATION FOR 1954

During the calendar year 1954, the IEA held, aside from numerous sessions of its various working committees, two general meetings. The Executive Committee held a meeting in Paris, June 10-13, attended by all members, to make short- and long-range plans in view of the Ford Foundation grant extending over five years, from July 1 of this past year. Among other things, plans for an expanded program of round table conferences, with emphasis upon the participation of economists from the less developed countries, resulted from this meeting. The Executive Committee, in view of the growth of the number of member associations and the consequent increase in the size of the Council, decided to reduce the number of each association's delegates to the Council from four to two or from two to one, depending upon the category of the country.

A round table on wage determination was held September 4-13, at Seelisberg, Switzerland, with thirty-five participants from fourteen countries. The program was planned by John T. Dunlop (United States), Jean Marchal (France), and G. Demaria (Italy). A volume containing twenty background papers and a record of the Seelisberg discussions is being prepared and will probably be published, as earlier volumes have been, by Macmillan, London.

During the past year, the International Economic Association has published Volume 4 of the series of articles translated into English and bearing the title, *International Economic Papers*. A fifth volume is being prepared and it is hoped that, as in the case of Volume 4, UNESCO will contribute a subsidy of $1,000. A volume entitled, *Monopoly and Competition and Their Regulation,* edited by E. H. Chamberlin, contains the background papers and a record of the discussion of the round table held on this theme at Talloires (France) in September, 1951. The book was published by Macmillan, London, and is being sold in the US by the St. Martin's Press, New York. Sales of the volume have been good despite the price of $7.50. A condensed version of the papers and discussion of economic progress in the round table on this subject at Santa Margherita during the first week of September, 1953, has been published in UNESCO's *International Social Science Bulletin*, Volume 6, 2 (Summer, 1954). Complete texts of the papers and a fuller account of the sessions are being published in December, 1954, in mimeographed form by the Institut de Recherches Economiques et Sociales, at Louvain, Belgium.

For the more immediate and more distant future, the International Economic Association has plans in various stages of advancement for several round tables and other conferences. For three years, a committee under the chairmanship of Brinley Thomas (Cardiff, Wales; other members, Sauvy and D. Glass) has been perfecting a program on international migration, which is now scheduled for September, 1955, in Western Austria. The meeting will be partly supported financially by the Intergovernmental Committee on European Migration (Geneva). The Association is also planning a round table or seminar on

the economic development of Latin America, to be held under joint auspices with the Economic Commission for Latin America in December of 1956 at Rio de Janeiro. The Association committee—Howard S. Ellis for the Executive Committee, Eugenio Gudin (Brazil), Javier Marquez (Mexico), and Henry Wallich (United States)—has drawn up tentative plans. UNESCO will probably contribute $10,000 to this conference. During the coming summer, a refresher course in economics, planned by the IEA, represented by Austin Robinson, and the Indian Economic Association, represented by C. N. Vakil, will be held at a hill station in northern India. The purpose is to help Indian economists, particularly teachers of advanced students in the universities, to become or remain *au courant* in the recent developments of economics. The Indian government has made a substantial grant to finance the attendance of Indian economists, and the IEA will cover the expenses of four or five economists from Europe and the US who will offer courses. A similar refresher course for economists in the Middle East is being studied by two members of the IEA Executive Committee: Emile James (France) and Xenophon Zolotas (Greece).

Preparations are nearly complete for the First Congress of the International Economic Association, to be held September 4-9, 1956, upon the invitation of the Rector of the University, Professor U. G. Papi, at the University of Rome. Five principal speakers have undertaken to present main papers and these will be discussed by ten economists of international distinction. Announcements of this Congress are now being printed and will be inserted in the issues of national economic association journals appearing in the early months of 1955. The meetings are open to all members of all member associations. The text of main papers will be available at each session in translation into three or four languages, and provision will be made for stimultaneous or sequential translation of discussions. The theme of the Congress will be, "Stability and Progress in the World Economy."

For the more remote future, round tables are contemplated on the philosophical foundations of economics, being prepared by Alfred Stonier and Douglas Hague (University College, London); on the economic implications of the size of nations, preparatory explorations in December, 1954, in Paris by Austin Robinson, Lorie Tarshis, I. Svennilson, and Duquesne de la Vinelle; and on the development of southern Italy.

As far as concerns the relations of the AEA to the IEA, there are at present only two items of business—one rather routine and the other of considerable long-range importance. As for the first, consonant with the reduction of the size of the Council, the AEA should, prior to the Council meeting of 1956, select two of its present four representatives to be alternates rather than members and thereafter appoint only two members. As for the second, the Executive Committee of the IEA requests its constituent member societies to give early consideration to the problem of the finances of the IEA upon the expiration of the Ford Foundation grant. Perhaps a "hump" in the activities of the IEA is inevitable, but too great a decline after four years would be fraught with substantial disadvantages.

Respectfully submitted,

HOWARD S. ELLIS

REPORT OF OUR REPRESENTATIVE TO THE SOCIAL SCIENCE RESEARCH COUNCIL

Two years ago in reporting on the Council's activities I noted that a Rockefeller Foundation capital grant of $1,500,000 had placed the Council's finances on a more stable basis. At the Council's spring meeting this year President Herring reported that since September of 1953 the Council had received additional grants of over a million dollars. These grants are designed primarily to develop individual research and researchers rather than to promote group research projects. In a society in which bigness and organization are almost becoming fetishes, it has perhaps been inevitable that social science research should suffer from what has been aptly called "projectitis." The Council's renewed concern with the development of the research talents of and opportunities for the lone researcher seems particularly commendable. These grants make possible a continuation of the Council's research training fellowships, faculty research fellowships, first year graduate study fellowships, and the grants-in-aid program on a substantially larger scale.

Council activities of the past year of particular interest to economists include the work of the following committees: agricultural economics, business enterprise, census monographs, economic growth, labor market research, mathematical training of social scientists, and Slavic studies.

The Committee on Agricultural Economics reported at the Council's fall meeting that it hoped to complete soon its study of research on areas of persistently low incomes and low productivity, but it reported difficulties in financing its projected handbook on research techniques in agricultural economics. Meanwhile this project is inactive.

The Committee on Business Enterprise research met in February and July. It plans a conference in the fall of 1955 on "Expectations, Uncertainty, and Business Behavior" and a second conference in 1956 on some other aspect of research on the business enterprise. The committee's chairman, Howard Bowen, has completed his monograph on *The Business Enterprise as a Subject for Research* and the Council will publish it sometime in 1955.

Of the twenty monographs which it has projected, the Committee on Census Monographs has sent two to the printer: *American Agriculture, Its Structure and Place in the Economy* and *Income of the American People*. It reports that five others are nearing completion: *Older Population of the United States; Residential Financing; Social Characteristics of Farm, Village, Town and Urban Populations; Foreign Born and Ethnic Population Groups; Child and Youth Population.* Eleven monographs dealing with various aspects of the housing problem, occupational trends, structure of the labor force, internal migration, differential reproduction, and related topics are in a less advanced stage of preparation, while two have not yet been assigned.

The Committee on Economic Growth, under Simon Kuznets' chairmanship, is bringing to completion the program it projected some two years ago. The

Duke University Press is publishing the papers presented at the 1952 conference on economic growth in Brazil, India, and Japan. The Committee conducted four conferences during the past year, dealing respectively with strategic factors in periods of rapid economic growth, cities and their role in economic growth, entrepreneurship and economic growth, and economic criteria in investment plans for development. The Committee has arranged with economists in England, Germany, Italy, and Sweden to appraise estimates on national income and wealth extending back over a century or more and to report on their findings within a year after beginning the project. The Committee reports: that the International Association for Research on Income and Wealth, with headquarters in Italy, will publish the several papers on economic growth presented at the Association's 1953 meeting; that the Committee's chairman presented a paper entitled, "Toward a Theory of Economic Growth," at Columbia University's third bicentennial conference in May; and that at the invitation of the population division of the United Nations the chairman participated in a conference on plans for further research on the economic and social implications of population trends.

The work of the Committee on Labor Market Research is nearing completion. In June the Council published the Committee's final report on its study of labor mobility under the title, *Labor Mobility in Six Cities; A Report on the Survey of Patterns and Factors in Labor Mobility, 1940-50.* The Committee has published a second volume entitled *Labor Mobility and Economic Opportunity,* under the imprint of the Massachusetts Institute of Technology and John Wiley & Sons and a third volume on *Research on Labor Mobility; An Appraisal of Research and Findings in the United States,* authored by Herbert Parnes and appearing as Council Bulletin 65. After tentatively canvassing other directions in which research might be desirable, the Committee proposed that it be continued into the coming year to formulate its recommendations to the Council.

After obtaining reports from three-fourths of the participants in the 1953 Hanover institute on training in mathematics evaluating their experience, the Committee on Mathematical Training of Social Scientists has arranged for two institutes to be held simultaneously in the summer of 1955—one at the University of Michigan and one at Stanford. The Committee has also inaugurated three projects for preparing teaching materials for certain social science fields. Two are of particular interest to economists. Harold W. Kuhn is preparing problems and exercises in the theory of games and linear programing and Robert R. Bush is preparing similar materials in other areas of economics.

The Committee on Slavic Studies reports that the Rockefeller Foundation will meet one-half the cost of financing for the next five years the Committee-sponsored *Current Digest of the Soviet Press* and the Committee is taking steps to obtain the additional money needed to finance the work. In May, 1954, the Committee sponsored a conference at Arden House on "Continuity and Change in Russian and Soviet Thought," and the twenty-six papers presented at the conference are being edited for publication.

In 1947, at the request of the American Economic Association the Council helped in financing the translation of August Lösch's *Die räumliche Ordnung*

der Wirtschaft. After some delay occasioned by problems raised by the Alien Property Custodian, the work has been completed and the Yale University Press has published the translation.

In terminating my six years membership on the Council's Board of Directors, the last year as chairman, I wish to express appreciation to the Association and the Council for a stimulating and interesting experience.

Respectfully submitted,

GEORGE W. STOCKING

REPORT OF OUR REPRESENTATIVE TO THE AMERICAN COUNCIL OF LEARNED SOCIETIES

The main duty of the delegate is to attend the annual meeting, which was held in Rye, New York, in January, 1954. He also reads the minutes of all meetings of the Board of Directors. The main work of the Council must be learned from its published *Proceedings*. The shortened Council meetings of recent years are largely taken up with the routine of reports from the Executive Director (now Dr. Mortimer Graves) and other officers and staff of the Washington headquarters, of some of the committees through which the Council chiefly works, the election of officers, etc. Available time is devoted to discussion of general or timely topics of concern to the interest of scholarship in the country, hence to those who are chosen to speak for this interest, as organized in professional societies in the humanities and the social sciences.

For reasons that will be obvious in a general way, the organization has of late been increasingly concerned with relations between scholarly work and the government. There are matters of freedom of international movement of both materials and individuals; also the interruption of promising careers by draft for military service. Here the authorities have shown a disinclination to consider scholars in the fields represented as of special importance, particularly in comparison with workers in natural science. Further, the federal government is responsible for important scholarly activities and institutions. In January, 1954, the appointment of a Librarian of Congress was impending and reports indicated that considerations other than the best possible conduct of this vital agency were being pushed to influence the selection. The question of how far and how the Council or its twenty-four constituent societies should try to affect governmental action in such matters gave rise to some lively discussion, ending with the action that seemed most likely to receive consideration. An excellent statement in answer to the charges made against tax-exempt foundations by the Reece committee was prepared and submitted by Messrs. Graves and DeKiewiet.

At the present juncture, the matter that is naturally of most acute concern in ACLS circles is that the Council's existence is in jeopardy for lack of financial support. The occasion is that the foundations, which have long supplied the bulk of the "overhead" financing, the support of the central office and staff, have announced early discontinuance of grants for this purpose. At the meeting there was considerable discussion of the functions of the Council and methods of making the need for it appreciated by the foundations or other possible sources of support. From the AEA point of view, it is to be noted that the social science society constituents of the ACLS have been somewhat out of the main focus of its activities since the organization of the SSRC. This was not in prospect when the ACLS was set up, immediately after World War I, to represent this country in international relations of scholarship and re-

search in fields other than natural science. Your delegate would, however, express the conviction that the work of the ACLS and representation in it of the social sciences, alongside the more distinctly humanistic groups, is both of national importance and of substantial value to the former associations and their membership. If so, the AEA should co-operate in any suitable way in securing provision for the Council to continue with adequate support for effective work on at least the scale of recent years. I have no specific recommendation to offer in that connection at this time. The matter will undoubtedly receive the earnest consideration of our Executive Committee whenever there is any occasion for action.

Respectfully submitted,

FRANK H. KNIGHT

WORK OF THE NATIONAL BUREAU OF ECONOMIC RESEARCH IN 1954

Thirteen reports resulting from the National Bureau's work were published in 1954. On December 31 eleven were in press. Three were approved and about ready to go to press, and seven were being reviewed, or were soon to be reviewed, by the Board of Directors. A number of others were in an advanced stage of preparation and work on several new projects was under way and advancing effectively.

New Studies Started and Planned

New research in the field of international economic relations developed still further in 1954. A study of the structure of world trade and payments, the possibilities of which Herbert B. Woolley explored in 1952-53, was developed in 1954 with the assistance of a grant from the Ford Foundation. Earl Rolph undertook a brief exploratory study of change in the public debt of various countries since 1914, bringing into consideration related changes in price levels and currency valuation.

The review of what is known of the economic growth of Soviet Russia, started in the autumn of 1953 with the aid of a grant from the Rockefeller Foundation, was developed rapidly in 1954. It is being directed by Raymond W. Goldsmith and concerned primarily with the question: What has been the growth of Soviet Russia's output over the past three decades?

With the assistance of a grant from the Alfred P. Sloan Foundation, work was started late in 1953 and continued actively in 1954 on a project that will render an account of the course of money and real wages in the United States from the Civil War to the present day and of the changes at least since the turn of the century in the relations between the volume of output on the one hand and the quantities of labor and capital employed in production on the other. Leo Wolman is in charge of the wage study and John W. Kendrick is directing the work on productivity.

With a grant from the National Science Foundation, a study dealing with methods of determining the demand for and supply of scientific and technical personnel was started in 1954 by George J. Stigler.

Upon the suggestion of the Council of Economic Advisers– and in view of the widespread interest in the applicability of the National Bureau's business cycle investigations to the problem of forecasting—new studies in this area have been started under the direction of Geoffrey H. Moore. These studies are reviewing the possibilities and limitations of statistical indicators of cyclical swings, the measurement and interpretation of indexes of scope or diffusion of business fluctuations throughout the economy, and the usefulness for forecasting purposes of data on businessmen's expectations.

Ilse Mintz has begun an investigation of cycles in foreign trade of the United States; and Millard Hastay has begun a study dealing with "long cy-

cles" in economic activity for the purpose of throwing further light on the character and extent of long swings in our economy.

A study of postwar capital markets was planned in 1954 and a grant for its conduct was authorized by the Life Insurance Association of America. It is expected to be organized and operations begun in 1955.

Research associates appointed for 1954-55 and the fields in which they have started and currently have projects under way, are:

1. George Borts, Business Cycles—Regional Fluctuations
2. Michael Gort, Capital Formation and Financing
3. George S. Brinegar, Agricultural Finance

Universities-National Bureau Committee for Economic Research

The Universities-National Bureau Committee for Economic Research, which had been enlarged in 1950 to include twenty-eight universities offering graduate work in economics and emphasizing research, completed its first four years on June 30, 1954, and has now been continued for the period July 1, 1954-June 30, 1958.

Two Special Conferences, the fourth and fifth under the sponsorship of the Committee, were held in 1953. One of the two was on "Policies to Combat Depression," held at Princeton University in October. The second was on "Capital Formation and Economic Growth," held in November at the Carnegie Endowment International Center in New York.

The sixth Special Conference was held at Princeton University in May, 1954, and was devoted to further discussion of the same subject as the fourth; namely, "Policies to Combat Depression."

The seventh Special Conference was held in September, 1954, and was devoted to "Measurement and Behavior of Unemployment." Plans have been completed for the eighth conference, to be devoted to consumption economics, which will be held in 1955. A topic in international economics is proposed as the subject for the ninth Special Conference, to be held in 1956, and steps are now being taken to prepare plans for it.

The 1954 Annual Meeting of the Conference on Research in Income and Wealth was held in October of that year and was devoted to discussion of the comparability of national accounts. The 1955 Annual Meeting will be devoted to a review of the existing national income statistics of the United States.

Papers presented at the two Special Conferences on Policies to Combat Depression, held in October, 1953, and May, 1954, at the Conference in November, 1953, on "Capital Formation and Economic Growth," and those on capital formation presented at the 1953 Annual Meeting of the Conference on Research in Income and Wealth, are now being edited and prepared for publication.

Relocation of Offices

On May 1, 1954, the National Bureau moved its offices from 1819 Broadway and from "Hillside" to 261 Madison Avenue, New York City. The decision to move became necessary when the decision of the City of New York to build

the projected Coliseum at Columbus Circle and to demolish the building in which the National Bureau's offices were located became final late in 1953.

Directors, Officers, and Staff

C. Canby Balderston, elected Chairman of the Board of Directors at the 1954 Annual Meeting, resigned in August as Director by Appointment of the University of Pennsylvania and as Chairman of the Board upon his appointment as a member of the Board of Governors of the Federal Reserve System. Percival F. Brundage, elected President at the 1954 Annual Meeting, resigned in May as President upon his appointment as Deputy Director of the Bureau of the Budget. Harry Scherman was elected President to fill the unexpired term by resignation of Mr. Brundage.

John H. Williams was elected Director by Appointment of the American Economic Association to fill the unexpired term of Donald H. Wallace who died September 19, 1953. At the 1954 meeting of the Board, Melvin G. de Chazeau was elected Director by Appointment of Cornell University to succeed Paul M. O'Leary whose term of office had expired, and Solomon Fabricant was elected a Director at Large. C. Reinold Noyes, Director at Large, resigned as a member of the Board on June 30, 1954.

Solomon Fabricant, who had served as Acting Director of Research in 1953, was appointed Director of Research on March 1, 1954, to succeed Arthur F. Burns, who went on leave of absence on March 19, 1953, to serve as Chairman of President Eisenhower's Council of Economic Advisers.

George H. Borts, of Brown University, George Brinegar, of the University of Connecticut, and Michael Gort, of the University of California, were appointed research associates for 1954 and 1955.

Members of the Association may make suggestions relative to the work of the National Bureau either directly or through the member of the Board of the National Bureau by appointment of the Association.

CHARLES HENRY HULL

Treasurer of the American Economic Association, 1896-99
Secretary-Treasurer, 1900 to June, 1901

Charles Henry Hull was born in Ithaca, New York, September 29, 1864. His life was devoted very largely to the activities of the city of Ithaca and Cornell University. He received his Ph.B. degree at Cornell in 1886 and except for two years, 1890-92, when he was a student at Gottingen, Halle, and Berlin, he spent his entire academic career at Cornell. He received his Ph.D. degree at Halle in 1892.

Hull's first appointment was in the Cornell University Library in 1886 and he became assistant librarian in 1887. After returning from abroad in 1892, he became instructor in political science and in 1893 was promoted to assistant professor of political economy, which post he held to 1901, when he was made professor of American history, the position which he occupied until he became emeritus professor in 1931. He died unmarried, June 15, 1936.

Although he always regarded teaching as his first obligation, he served as secretary of the University faculty, dean of the College of Arts and Sciences, and faculty member on the Board of Trustees. He also participated actively in community affairs, such as the Co-operative Society, the Town and Gown Club, the Community Chest, the Hospital Association, the Board of Education, the Chamber of Commerce, and Cornell University Library Association

Professor Hull published little, but not withstanding this fact, he achieved high distinction as a scholar. His edition of *The Economic Writings of Sir William Petty*, published when he was thirty-four years of age, was at once pronounced by competent critics a masterpiece of its kind.

Charles H. Hull

The American Economic Review

VOLUME XLV JUNE, 1955 NUMBER THREE

RELATIVE PRICES AND AGGREGATE SPENDING IN THE ANALYSIS OF DEVALUATION

By Fritz Machlup*

Two approaches to the question of the effects of devaluation have been presented as alternatives, and one of them has been treated as inferior, if not absolutely inappropriate.[1] The purpose of this article is to examine the supposedly superior approach and to give a comparative evaluation of both.

The problem is how to analyze the probable effectiveness of a devaluation undertaken to remove or reduce an existing excess demand for foreign exchange without the use of direct controls, when money incomes have been stable, and when no autonomous capital movements take place either before or after the devaluation. These restricting conditions serve to present the problem in splendid isolation from certain very realistic conditions—such as the presence of direct controls or of autonomous capital movements—from which abstraction must initially be made in a clean analysis.

We are not concerned here with the question whether devaluation is the "most appropriate" policy under given circumstances, or under what circumstances devaluation would be "more appropriate" than other policies. Our question is merely this: what is the best way of finding out whether devaluation will reduce the trade deficit, or what per cent of devaluation would eliminate a given trade deficit, or what size of a deficit would be eliminated by a given per cent of devaluation?

I refer to the two ways of analyzing the problem as the *relative-prices* approach and the *aggregate-spending* approach. Alexander called them the "elasticities approach" and the "income-absorption ap-

* The author is professor of political economy at the Johns Hopkins University.

[1] S. S. Alexander, "Effects of a Devaluation on a Trade Balance," Internat. Mon. Fund *Staff Papers*, Apr. 1952, II, 263-78.

proach."[2] There are other possible names: the "supply-and-demand approach" and the "income-and-outlay approach"; or, with an allusion to doctrinal history, the "Marshallian approach" and the "Keynesian approach" to the problem.

I. *Deficiencies of the Relative-Prices Approach*

The most widely used version of the relative-prices approach works with supply and demand curves for foreign exchange. The positions and shapes of these curves, and thus their elasticities at various points, are "deduced" from the supply and demand for exports and from the supply and demand for imports; and all these, in turn, are "deduced" from the supply conditions and demand conditions in all foreign and domestic markets, because every supply in foreign trade is an excess supply over domestic demand, and every demand in foreign trade is an excess demand over domestic supply.

Now the question has been raised whether one can take the shape of any of these curves as given; whether one can regard their elasticities as predetermined and use them in the solution of foreign-exchange problems. I had thought it useful to assume so,[3] and so had many others.

Given and Unchanged Cost Conditions

We said, for example, that the supply of exports would depend in part on "cost-conditions"—as if cost conditions were something definite. But is this defensible? The cost of *one* product can be shown in a curve, other things being given and unchanged; but if other things change, the cost curve no longer stays put; if the production of many goods is to change at the same time, we cannot easily know what the cost curve for any one of them will do.[4]

In the production of a certain good, productive resources are needed; for the production of more of that good, more resources are needed. If not much is happening elsewhere, one may foretell at what prices additional resources may be available, and one may, on the basis of technological knowledge, foretell what the cost of additional output will be. But for the prices of additional resources it will make a great difference whether at the same time these resources are being released by other industries or are being demanded by them in increased amounts.

[2] Alexander obviously means price elasticities by the first name, since income elasticity of demand plays a main part in the second approach.

[3] Fritz Machlup, "The Theory of Foreign Exchange," *Economica*, Nov. 1939, VI, 375-97, and Feb. 1940, VII, 23-49. Reprinted in *Readings in the Theory of International Trade* (Philadelphia, 1949), pp. 104-158.

[4] For an excellent exposition of the general problem of cost and supply curves, see Joan Robinson, "Rising Supply Price," *Economica*, Feb. 1941, VIII, 1-8. Reprinted in G. J Stigler and K. E. Boulding, ed., *Readings in Price Theory* (Chicago, 1952), pp. 233-41.

It is possible that, when the production of a certain product rises, say in order to provide increased exports under the stimulus of a devaluation, the production of other goods may be cut and productive services released to the expanding export industry. But it is also possible that some other industries will increase their output under the stimulus of the same devaluation, and that they also will require more of the same productive factors; and if several industries simultaneously demand these factors, their prices will rise. Where then are our "given" cost conditions?

Given and Unchanged Incomes

A second argument against the relative-prices approach is the possibility of changes in incomes. The devaluation itself may have income effects: incomes may rise or fall as a result of the devaluation. But the supply and demand curves are drawn, of course, on the basis of a given buying power, a given income. Thus, these curves will not help much if we know that incomes must have changed; we have to know how income has changed and how the new curves look.

Even if we did not allow total money income to change (and we shall return to this point), there is still the possibility of significant changes in income distribution. After all, devaluation will raise the domestic prices of imported goods which may be important in the budgets of certain groups; this would alter the distribution of real income. But if income distribution changes, demand is likely to change and our curves again may shift considerably.

That these arguments make it necessary to qualify and supplement the "simple" elasticity analysis had been clear to many.[5] But what Alexander suggests amounts to a repudiation of the relative-prices approach.[6] His arguments are persuasive and, with our confidence in

[5] The income effects of devaluation have often been discussed. I wrote: "If depreciation through its effects upon the volume of exports or upon the balance or the terms of trade should raise or lower total income, it would probably also raise or lower the demand for imports. These income effects of depreciation may be negligible in the beginning, but in the course of time, as the 'multiplier mechanism' becomes operative, they may become strong enough substantially to weaken or reinforce the price effects of depreciation." "Elasticity Pessimism in International Trade," *Econ. Internaz.*, Feb. 1950, III, 11. See also, J. J. Polak, "Discussion," *Am. Econ Rev.*, Proceedings, May, 1952, XLII, 180-81; A. C. Harberger, "Currency Depreciation, Income, and the Balance of Trade," *Jour. Pol. Econ*, Feb. 1950, LVIII, 47-60; T. Balogh and P. P. Streeten, "The Inappropriateness of Simple 'Elasticity' Concepts in the Analysis of International Trade," and "Exchange Rates and National Income," *Bull. Oxford Univ. Inst. Stat.*, Mar. and Apr. 1951, XIII, 65-77, 101-08.

[6] ". . . the total elasticities appropriate for the analysis of the effects of a devaluation depend on the behavior of the whole economic system, and the statement that the effect of a devaluation depends on the elasticities boils down to the statement that it depends on how the economic system behaves." ". . . it is suggested that a more fruitful line of

the criticized approach shaken or destroyed, we are eager to examine the novel approach that is offered as a superior substitute.

II. *Alexander's Aggregate-Spending Approach*

The new approach to the problem of the effect of devaluation is the aggregate-spending approach, or "income-absorption" approach. While following Alexander's exposition, I shall slightly change the notations.

The Fundamental Equation

The *total income* of a nation can be divided or classified into *consumption* plus *investment* plus *government contribution*[7] plus *exports* minus *imports;* or

$$Y \equiv C + I + G + X - M.$$

This identity is used as the fundamental equation; it can be shortened by merging the first three terms on the right side, that is by calling C plus I plus G by the name "absorption,"[8] or A. (The expenditures of households and business and governments are the part of the national income that is being "absorbed.") The two remaining terms of the identity, X minus M, the difference between exports and imports, constitute the trade balance, signified by B. Thus, what we now have is that the *national income* is the sum of the *absorption* by the nation plus its *trade balance;* or

$$Y \equiv A + B.$$

It follows that the trade balance must always be the difference between income and absorption:

$$B \equiv Y - A.$$

The trade balance is negative when the nation absorbs more than its income. The trade balance can improve if income increases while absorption increases less or stays unchanged or falls; or if absorption decreases while income decreases less or stays unchanged.

Devaluation Effects on Income and Spending

The question we now have to ask is to what extent devaluation can

approach can be based on a concentration on the relationships of real expenditure to real income and on the relationships of both of these to the price levels, rather than on the more traditional supply and demand analysis." Alexander, *op. cit.*, pp. 264, 263.

Balogh and Streeten also rejected the "elasticities approach": ". . . we shall contend that this approach to the problem is erroneous" (*op. cit.*, p. 65). But they did not suggest an alternative one: "It is regrettable but inevitable that no single new method of analysis can be put into the place of the old approach" (*ibid.*, p. 66).

[7] This term was not included in Alexander's exposition.

[8] This term was first used by K. E. Boulding, *Economic Analysis* (New York, rev. ed., 1948), pp. 402-8.

affect B, that is, the difference between income and absorption. Alexander breaks this down into three questions:[9] (1) How does devaluation affect income (Y)? (2) How does a change in income (ΔY) affect absorption (A)? (3) How does devaluation directly (that is, not via income) affect absorption (A)?

The change of the trade balance is the change in income minus the change in absorption; or

$$\Delta B \equiv \Delta Y - \Delta A.$$

The effect of devaluation upon income will show in ΔY; the effect of the change in income upon absorption, and the direct effect of devaluation upon absorption, will both show in ΔA. In other words, there will be an income-induced change in A and a nonincome-induced, or directly effected, change in A. The direct effect of the devaluation upon absorption can be expressed by δA. The income-induced change in absorption can be expressed by $a\Delta Y$, where a is the "marginal propensity to absorb income" (which of course will be the sum of the marginal propensities to consume, to invest and to spend public funds).

The new symbols help to merge the devaluation effect upon income, ΔY, and the income effect upon absorption $a\Delta Y$, into a single expression $(1 - a)\ \Delta Y$, which stands for the nonabsorbed change in income. Thus,

$$\Delta B = (1 - a)\ \Delta Y - \delta A.$$

Assume, for a moment, that income will increase as a result of devaluation. This devaluation effect upon income and the consequent income effect upon absorption will improve the trade balance only if a is smaller than unity. But, while the marginal propensity to consume is usually smaller than unity, a, the combined marginal propensity to consume, invest, and spend publicly, may well be greater than unity. If so, $(1 - a)\ \Delta Y$, the nonabsorbed change in income, will be negative and the trade balance will deteriorate, rather than improve, on this score. Only the direct effect on absorption can then still help matters.

Alexander states that the analysis on the basis of his model will hold in real terms as well as in money terms; he then proceeds in the belief that he talks about real income, real absorption, and real trade balance throughout.

Following the clue from the last equation, Alexander divides the further discussion into two parts: the effects upon and via incomes—

[9] *Op. cit.*, p. 266

$(1 - \alpha)\ \Delta Y$—and the direct effects upon absorption—δA. He recognizes the following effects:

Effects upon and via Income $[(1-\alpha)\Delta Y]$	Direct Effects on Absorption $[\delta A]$
	Cash-balance effect
Idle-resources effect	Income-redistribution effect
Terms-of-trade effect	Money-illusion effect
	Three other direct absorption effects

The Idle-Resources Effect

If the devaluing country has idle resources, their employment can be increased by additional consumption, investment, government expenditures, or exports. Since C and I (and tacitly, G) are assumed by Alexander to be functions of income, additional exports are the strategic factor; and additional exports are the very thing that one should expect to result from devaluation.

The increased value of foreign moneys in terms of domestic money stimulates the production of export goods; if idle resources are available, employment will increase in the export industries; as the recipients of the income increment spend it for consumption, further employment may be created in the consumers-goods industries. This process is the familiar operation of the "foreign trade multiplier." But while the multiplier, in the customary exposition, includes only induced consumption, Alexander's employment effect comprises induced spending of all kinds.

Alexander inclines to the belief that α is greater than unity, that $(1 - \alpha)$ therefore is negative, and consequently that the trade balance will become worse as a result of the income increase due to the idle-resources effect of the devaluation. If improving the trade balance is the policy objective, it would follow that the devaluing country must hope either that there will be no increase in its income and employment, or that the propensity to absorb income is less than unity—or at least that the other effects of devaluation will be in the right direction and stronger than the idle-resources effect.

The Terms-of-Trade Effect

Alexander joins the majority of economists in the belief that devaluation will deteriorate the terms of trade of the devaluing country. He thinks that this is so because "a country's exports are usually more specialized than its imports."[10]

[10] *Ibid.*, p. 268.

If devaluation affects the terms of trade, the change in the terms of trade will affect national income and absorption. Alexander divides the terms-of-trade effects of devaluation on the balance of trade into an initial effect through price changes and a secondary effect through income-induced changes in absorption. He holds that "the normal result of a devaluation will be such deterioration of the terms of trade of the devaluing country as to" cause an initial deterioration of its balance of payments equal to "the reduction of the country's real income associated with the deterioration of the terms of trade."[11] In other words, the initial effect will normally be an equal and simultaneous reduction (deterioration) of the trade balance and of real national income. The secondary terms-of-trade effects of devaluation upon the balance of trade—the income-induced changes in spending—will depend on the marginal propensity to absorb income. The income-induced changes in absorption may either reinforce or attenuate the initial terms-of-trade effect on the balance of trade, or may turn it in the opposite direction.

Alexander, having concluded that the *initial* terms-of-trade effects upon trade balance and upon real income are (normally) equal in direction and in amount—he uses one symbol, t, for both—believes that he can find the ultimate terms-of-trade effect upon the trade balance by multiplying the initial effect by the marginal propensity not-to-absorb. Hence, the ultimate terms-of-trade effect upon the balance of trade would be $(1 - \alpha)t$, and thus could be positive (*i.e.*, improving the balance) only if (since t is assumed to be negative) $1 - \alpha$ is negative, that is, if α is greater than unity.

The Income Effects Combined

Alexander combines the two "income effects of devaluation" which he recognizes—the idle-resources effect and the terms-of-trade effect—in one expression equivalent to $(1 - \alpha)\ \Delta Y$. This presupposes that a change in the terms of trade resulting from devaluation will affect the balance of trade only through the change in real income, and to an extent commensurate with it.

Either or both of the income effects of devaluation may be zero. The idle-resources effect—"presumably positive," according to Alexander—can be positive only if there are unemployed resources and if their employment is not obstructed by bottlenecks (lack of complementary factors or lack of finance). The terms-of-trade effect may be zero if devaluation does not change the terms of trade, or if the "initial" effects on the trade balance as well as the "secondary" effects

[11] *Ibid.*, p. 269.

through income-induced changes in spending are checked or counteracted by monetary policy.

Direct Effects on Absorption

Effects of devaluation upon the balance of trade which are not associated with changes in income but only with changes in the absorption of a given income, are called "direct effects on absorption." If there is no change in income, the trade balance can be increased only through a reduction in the domestic absorption of income, *C*, *I*, or *G*, and an equal increase in exports or reduction in imports. Such a switch from *A* to *B*, from domestic absorption to foreign-trade balance, can possibly be accomplished without transfer of productive resources or changes in production if the reduction in domestic absorption relates to imported goods or to exportable goods. Otherwise it will require a shift of production from goods and services hitherto used for *C*, *I*, or *G* to goods and services for *X*, or to goods and services substituted for *M*. This will involve not only adaptations in production plans but ordinarily also a transfer of productive resources between plants, firms, industries, and locations. The question is, what mechanisms are set in motion by devaluation to induce these adaptations and transfers, and what obstacles have to be overcome in the process?

A reduction in consumption and investment can, in general, lead to a reduction in employment and income just as easily as to an increase in the trade balance.[12] Whether the productive resources released from domestic *C* and *I* industries will remain idle or will be transferred to industries producing *X* and substitutes for *M*, will depend chiefly on how the economy responds to price incentives; this need not involve price reductions, because the release of the resources will have been preceded by an increase in prices of export goods and of substitutes for import goods. Moreover, the reduction in spending for *C* and *I* will have been offset by an increase in receipts for *X*. But the chief object in Alexander's discussion of the "direct effects on absorption" is to examine whether and how devaluation may bring about the reduction in domestic spending.

The Cash-Balance Effect

Devaluation raises the domestic prices of imports and of exports; and it will tend to raise the prices of import substitutes, of potential exports, and of intermediate goods required for their production. Thus, unless the monetary authorities restrict credit in order to force price reductions in other sectors of the economy, the price level will be somewhat increased as a result of the devaluation.

[12] *Ibid.*, p. 272.

If the monetary authorities do not create more money than may be needed to purchase the foreign exchange forthcoming as a result of positive devaluation effects on the trade balance, the elevated price level will imply a reduction in the real value of total cash balances. Households and firms will attempt to build up their cash balances to the relative size they have found appropriate. They will try to do this by buying less and by selling assets and securities (debts).

Buying less in order to accumulate cash balances implies "a reduction in their real expenditures relative to their real incomes,"[13] that is, a foregoing of consumption and investment. Selling assets and debts securities will depress their prices or, which is the same thing, increase interest rates. The offer of assets and debt securities at reduced prices would attract foreign buyers—which would greatly help matters—but we have excluded any autonomous capital movements from our analysis. With foreigners ruled out as buyers—because we wish to abstract from capital inflows in order to concentrate on the trade balance—and with banks ruled out as buyers— because we have excluded additional credit creation—there are only nonbank residents left as buyers, and they will overcome their liquidity preference only if the prices of securities are so attractive that it pays them to defer real investment, reduce consumption, and part with liquidity. The increased interest rates will have the effect of cutting down investment expenditures of business and consumption expenditures of households.

The Income-Redistribution Effect

The lift in the price level that is associated with devaluation may also reduce aggregate spending from a given income by redistributing it from groups with higher to groups with lower marginal propensities to spend. Alexander mentions three such shifts of real income: from fixed-income recipients "to the rest of the economy,"[14] from wage recipients to profit recipients, and from taxpayers to government.

A loss of real income which the recipients of fixed income suffer through increased prices will result in a reduction of aggregate absorption if the corresponding gain in real income accrues largely to people richer and thriftier than rentiers, fixed-salary workers, and pensioners —which is not unlikely.

A shift of real income away from wage earners will occur when wage goods are among those whose prices are raised through devaluation—which is rather common. If the shift of real income is towards profit recipients, their investment incentives may be increased by more than

[13] *Ibid.*, p. 271.
[14] *Ibid.*, p. 273.

the consumption demand of the real-income losers is reduced. And if investment outlays increase accordingly, total absorption of income may be increased rather than reduced.

A shift from taxpayers to government would most effectively cut down aggregate spending where government expenditures are not dependent on tax revenues but are fixed in an inflexible budget not to be stepped up with a larger flow of tax receipts. Income-tax receipts would be increased where an income redistribution takes place in favor of richer people and tax rates are progressive. And income tax receipts would also be increased where total money income is allowed to increase in consequence of devaluation.[15]

The Money-Illusion Effect

This is what Alexander has to say on the money-illusion effect:

> The money illusion may contribute a favorable effect to a devaluation if it actually leads people to pay more attention to money prices than to money incomes. If at higher prices people choose to buy and consume less *even though their money income has increased in proportion,* over and above what can be attributed to the cash balance effect, the result on the balance of payments will be favorable. But *rising money incomes and rising prices may actually operate in the opposite manner;* for example, annual savings may be calculated in money terms and may fail to rise in proportion to money incomes and prices.[16]

It should be noted that Alexander speaks here, in the italicized clauses, not of higher prices of foreign-trade-connected goods, but of rising prices and of money incomes rising in proportion.

Other Direct Absorption Effects

Three other direct effects of devaluation upon absorption, and thus upon the trade balance, are mentioned by Alexander. One of them, which we may call the "price-expectations effect," may unfavorably affect the trade balance by increasing absorption: people expecting prices to rise following the devaluation may rush out to increase their inventories.

The other two are favorable influences on the trade balance. What may be called the "high-cost-of-investment effect" consists in the discouragement which increased cost of imported investment goods may cause to investors. Investment that requires foreign equipment to be

[15] On the other hand, the revenues from specific import duties may be reduced rather than increased, and in many countries import duties are a significant portion of the budget.

[16] *Loc. cit.* Emphasis supplied.

imported at increased domestic prices, may be less attractive than it was before the devaluation and may be cut out altogether.[17]

The third effect generalizes the principle involved in the second effect to all kinds of imports: when certain goods, previously imported, become very expensive, some of the domestic buyers may give up buying these goods and may buy nothing instead. Alexander mentions this merely as a "theoretical possibility."

III. *Some Consequences of Neglecting Relative Prices*

My exposition of Alexander's analysis is, I hope, fair and accurate. In the first part of my critique I shall—without questioning the validity of the framework of the analysis or the merits of the procedure employed—point to some omissions and errors of reasoning which I believe can be attributed to Alexander's concentration on aggregate magnitudes and his neglect of relative prices. Although Alexander does not explicitly state that his enumeration of "income effects" and "direct absorption effects" is exhaustive, an impression is conveyed that, if not all, at least the more important ones have been covered. This, however, is not the case; we can find omissions in both categories.

The Resource-Reallocation Effect

There are three ways in which an increase in real national income can be achieved: through fuller employment of the available productive resources; through their better utilization and more economic allocation; and through more favorable terms of trade. Only two of these possibilities are recognized in Alexander's analysis: changes in the volume of employment and in the terms of trade. Transfer of resources to different uses does play a considerable role in his analysis, but only in connection with the direct absorption effects of devaluation. That such transfer may change real national income is not mentioned and has evidently been overlooked.

In the long run, greater economy and efficiency in the use of resources has been the most important factor in the increase in the living standards of the nations. In the short run, changes in the volume of employment and in the terms of trade may overshadow the effects of changed resources-use upon real income; but there is no presumption for one or the other to be more important. All three kinds of changes may be effected by devaluation (and each of them may be positive or negative).

[17] This seems to have been of considerable practical importance in several countries: Investment in imported labor-saving machinery, very profitable at predevaluation exchange rates, turned out to be too expensive relative to domestic labor once the exchange rates were corrected.

The "resource-reallocation effect" of devaluation may be especially significant when the "idle-resources effect" is negligible or zero; total employment may remain practically unchanged while the output produced may increase through a more economic or more efficient use of the resources employed. But it is also possible that both effects operate at the same time; more or fewer resources may be employed in a more or less economic way.

There are problems involved in measuring increases in real income when there are changes in the composition of output. Where the reallocation of resources implies a shift to "more valuable" products, with reductions in the output of "less valuable" products, the gain in real income can be measured only by means of a welfare index (based on market prices combined with other criteria). Even so, the principle that a reallocation of resources may increase the value of real output cannot reasonably be questioned. And where trade and production have been conducted on the basis of "unrealistic" exchange rates (overvaluing the currency) it is quite plausible that devaluation may effect a more economic use of resources with a consequent increase in real income.[18]

Substitution Effects

The resource-reallocation effect has been named here as another income effect of devaluation, although in Alexander's analysis resource reallocation is treated only in connection with direct absorption effects. But all of the direct absorption effects discussed by Alexander have to do with aggregate spending, with changes in the outlay of money; if they "work" to reduce total absorption they do so owing to the failure of some income recipients to spend all of their receipts or to make all the money expenditures they would otherwise have made.[19] Perhaps the most important absorption effects are thereby disregarded: the effects of shifts in relative prices and the effects of price increases which reduce real absorption even if absorption in money terms should be unchanged or slightly increased. This reduction in real absorption

[18] Besides the more economic resource allocation achieved through changes in relative prices, there may be two incidental resource-economizing effects of devaluation in systems operating with direct controls: one is the saving of administrative cost by government and by business when devaluation permits some controls to be removed and others to be improved; the second is the improved efficiency under the pressure of revived competition as the industry quota arrangements implied in the bureaucratic allocation of foreign exchange and imported materials are dropped when devaluation reinstates prices in the function of resource allocation.

[19] For example, in connection with the third of the three "miscellaneous direct absorption effects" Alexander says that "when the domestic prices [of imported goods] rise, the domestic purchasers cut their expenditures on these goods but save or hoard the difference, rather than shift the expenditures to other goods." *Op. cit.*, p. 274.

may be additional to that induced by a reduction in real income, although the increased prices may reflect such a real-income reduction.

Assume, for example (in order to isolate the outcome examined here from any terms-of-trade effects), that devaluation leaves the terms of trade unchanged, lifting the domestic prices of exports and of imports by the same percentage. As imported goods are now relatively higher in price than domestic goods, substitution in consumers' plans seems inevitable; and as exportable goods are now relatively higher in price than domestic goods, substitution in producers' plans seems inevitable; transfers of productive resources will ensue. And the increased demand for import-substitutes together with the reduced supply of domestic goods from the production of which resources have been diverted cannot but cause relative price movements which are apt to reduce the real value of aggregate absorption even if total money expenditures should be somewhat higher than before.

This reduction in real absorption will be additional to that induced by a reduction in real income if some among the substitutions induced take the form of shifts between consumption and asset holding (or indebtedness) or between investment and liquidity. Let us not forget that an import surplus implies an increase in indebtedness or decrease in the holdings of securities or other liquid assets on the part of some who absorb (consume or invest). Changes in relative prices may affect the willingness of "absorbers" to run up their debts or run down their liquid asset holdings. Substitution effects may significantly influence the absorption of real income and the physical volumes of imports and exports; these are price-induced changes in absorption, not predicated on any given "propensity to absorb" or on any general price level increase.

In all four kinds of direct effects on absorption discussed by Alexander, price movements play some role. But Alexander relies little on changes in *relative* prices to bring about the required adaptations and transfers.[20] Most of the time he looks to increased or rising price *levels* to do the trick. No wonder that he is disappointed in the performance.

The Terms-of-Trade Effect Amended

The neglect of the substitution effects impairs some of Alexander's analysis of the terms-of-trade effect of devaluation. It can be shown—although only in a lengthier exposition than we can here afford—that Alexander is in error when he holds that the initial effect—before any income-induced changes in absorption take place—will "normally" be an equal and simultaneous reduction (deterioration) of the trade

[20] Except in connection with the high-cost-of-investment effect.

balance and of real national income. To be sure, these two reductions can be made equal by definition, but it would be a rather useless definition; otherwise there is nothing that would cause the initial changes in trade balance and real income to be normally equal in amount or even in direction.

The source of Alexander's error in reasoning about the terms-of-trade effect lies in the conceptual decision to treat all effects of devaluation either as effects upon and via income or as direct effects upon absorption. Since a change in the terms of trade will affect income, Alexander at once puts the terms-of-trade effects under the first heading, and fails to notice that a change in the terms of trade will also affect absorption directly, through relative-price effects.

A change in the terms of trade may be viewed as a change in the ratio of an index of export prices to an index of import prices. The effects of relative price changes are customarily (following Hicks) divided into simultaneous income effects and substitution effects. By assuming that a change in the terms of trade will "initially" affect only income but not absorption, Alexander loses sight of the substitution effect. Absorption will actually be affected through both the substitution effects and the income effects of the change in the terms of trade. Thus, Alexander's conclusion that the ultimate terms-of-trade effect upon the balance of trade would be $(1 - a)t$, or equal to the income effect times the marginal propensity not-to-absorb, is wrong.[21]

IV. *Reasoning from Definitional Equations*

The argument underlying the aggregate-spending approach has been developed from a "fundamental equation" which represents mere definitions. Such equations usually serve a useful purpose in aiding the organization of the analysis. But they may easily tempt an analyst into "implicit theorizing," illegitimately deducing causal relationships, and overlooking the shifting meanings of terms in different contexts These temptations have not been successfully resisted in this instance.

Income and Output, Money Terms and Real Terms

As Alexander interprets the fundamental equation (or identity), "real income . . . is equal to the output of goods and services," and the relationships expressed "hold, of course, both in real and in money terms."[22] While this makes good sense for a closed system, it does not

[21] A clear exposition of the rather complicated relationships involved requires considerably more space, particularly because some fundamental questions concerning the use of terms-of-trade analysis ought to be explored at the same time. I reserve these tasks for a separate article.

[22] *Op. cit.*, p. 266.

for an open one, especially when the balance of trade plays a major role.

Even in a closed system there may be difficulties—due to problems of depreciation and depletion—in equating real income and output; but these difficulties can be defined away. In an open system where some output is produced for export, and imports contribute to consumption and domestic investment, output produced is not the same as real income. In order to relate output and income one would have to take account of changes in foreign assets and debts, as well as of unilateral transfers—items for which no provision is made in the equation. It is possible for employment, production, consumption, domestic investment, exports and imports, all to remain absolutely unchanged in physical terms, and for real national income nevertheless to be changed by some of the exports being sold at increased or reduced prices or given away free, or by some of the imports being bought at increased or reduced prices or received as gifts.

The conceptual difficulties implied in the possible deviations between changes in national product and national income[23] may have a significant bearing on the analysis of the effects of devaluation, especially in connection with changes in the terms of trade. What, for example, is the relevance of a "given" marginal propensity to absorb, when output and employment are affected one way, but income (with changes in foreign debts or assets) in another way? Will changes in absorption be induced by changes in employment and production or rather by changes in income that are partly due to changes in the foreign exchange reserves?

The supposed equivalence between relationships in money and in real terms is sometimes troublesome, occasionally even meaningless. Alexander intends to "deal only with real quantities, not with money values."[24] But what is a "real" trade balance? When a country has to pay increased prices for its imports and buys a slightly reduced physical quantity of imports, what is the meaning of an improved "real" trade balance if at the same time the balance in money terms has deteriorated? Or, should, perhaps, a trade balance in terms of money be translated into one in real terms by deflating the contracted foreign claims or debts by a price index? To treat exports and imports as "real quantities" makes sense; but can the difference between the two be meaningfully treated as a real (physical) quantity?[25] Can what is

[23] More correctly, possible deviations between changes in the total production of goods and services and in the total amount of income earned by the members of the economy. We are not concerned here with the difference between national income and disposable income.

[24] *Op. cit.*, p. 266.

[25] While horses and apples cannot be added, apples can be added *to* horses, but never subtracted *from* horses.

essentially an increase or decrease in foreign claims or debts be regarded as anything but a money value, however deflated?

Trade Balance in Foreign or in Domestic Money

But this is not all. Even if the concept of a trade balance in real terms is given up, the fact remains that, as a result of devaluation, an import surplus may increase in terms of domestic money and decrease in terms of foreign money. Indeed, this is a rather probable outcome.[26] But the ΔB in the equation $\Delta B \equiv \Delta Y - \Delta A$ is expressed either as a domestic money value or as the "real" equivalent of a domestic money value. This ΔB may be negative, so that a negative B may become even more negative, while the trade balance in terms of foreign money actually improves.

If one realizes that the whole purpose of the analysis is to find out what will happen to the trade balance of a country resorting to devaluation because of a shortage of foreign currency, one may be quite disappointed about the wrong result obtained. But, serious though it may sound, the damage is easily repaired by dividing $B + \Delta B$ by the increased exchange rate of the foreign currency: the deterioration of the balance in terms of domestic money may then show an improvement in terms of foreign money. It remains true, however, that $\Delta Y - \Delta A$ will not directly give the right answer.

Causal versus Ex Post *Relations*

The fundamental equation in the analysis, in the form $Y \equiv C + I + G + X - M$, is helpful in organizing an examination of the relationship between the components of aggregate spending and the foreign balance, but misleading if it is deemed to show causal *(ex ante)* rather than classificatory *(ex post)* relationships. For example, an increase in consumption expenditures may result in an increase in Y (if employment rises) or a decrease in I (if inventory is depleted) or a decrease in X (if exportable goods are domestically used) or an increase in M (if imports are purchased) or no real change at all (if prices of consumption goods rise); and there are many other more indirect possibilities and combinations—the study of which may be underemphasized by overconfident reliance on the "insight" afforded by the equation.

As a matter of fact, the equation gives very little insight into causal relationships. The merging of planned investment and unintentional inventory accumulation into one term, I, which in turn is part of A, is an example of an actually misleading "clue" suggested by the equation. Reduced consumption and reduced planned investment may some-

[26] See Machlup, "Theory of Foreign Exchange," *op cit.*, VI, pp. 375 ff. and *Readings*, pp. 104 ff.

times be offset by increased unintended inventory accumulation (due to the unexpected decline in sales). This latter part of ΔA is inversely related to ΔY as far as causal relationship is concerned; and, incidentally, the effects of devaluation upon planned inventory holdings may causally be more important than any positive relation between income and inventory investment.

The difference between causal and mere *ex post* relationships can perhaps be made clearer by asking for the meaning of the equation $\Delta Y \equiv \Delta A + \Delta B$. Obviously, if any two of these terms are given, the third can be calculated. But this is not to say that ΔB "depends" on $\Delta Y - \Delta A$ in any causal sense. To say this has no more merit than to say that ΔA "depends" on $\Delta Y - \Delta B$, or that ΔY "depends" on $\Delta A + \Delta B$.

Yet the "income-absorption" approach does rest on such "dependence" if it proposes that an investigation of the effect of devaluation upon the trade balance should proceed by analyzing the "basic questions" how devaluation affects both income and absorption.[27] With the same justification—or lack of justification—one might investigate the effect of devaluation upon national income by analyzing the "basic questions" how devaluation affects both absorption and the trade balance. And an analogous procedure might be proposed for an investigation of the effects of devaluation upon consumption and investment. Such an analytical merry-go-round is entirely "in character" whenever definitional equations furnish the sole basis for inquiry into presumably causal relationships.

Reversing the Direction of Causation

The income-absorption approach of analyzing the effect of devaluation upon B assumes that causation goes this way: devaluation affects Y; Y affects A; devaluation affects A directly; the net changes of Y and A determine the change of B.

At one point, however, the question of a reversible process is openly raised: if devaluation affects A directly, cannot A affect Y? No doubt, it can. If absorption is reduced as a direct result of devaluation, this may cause unemployment, partly or fully offsetting a positive idle-resources effect (due to increased activity in export industries) or even resulting in a net decline in employment and output.

In the event and to the extent that the directly effected reduction in absorption causes a net decline in employment (instead of the desired transfer of resources), a sequence of secondary nonspending will cut down consumption and investment even further, depending on the propensity to absorb; and if the transfer of resources should

[27] Alexander, *op. cit.*, p. 266.

still fail to take place, at least the purchase of imports will be reduced, with a definitely positive effect on the trade balance. Needless to say, no government would want to have the improvement of the trade balance take this form, but it is only fair to mention that it can happen. Analysts, however, may exclude this sequence of events by assuming that the government, pursuing a policy of full or high-level employment, will succeed in preventing a decline in employment.

V. *Implicit Shifts of Emphasis*

The income-absorption approach and the fundamental truism on which it rests may be helpful for the purpose of impressing the responsible leaders of the state as well as their economic advisers with the need "to recognize that, if the foreign balance is to be improved, the community as a whole must reduce its absorption of goods and services relative to its income."[28] At the same time the approach may be misleading in that it conceals the dependence of B (or of $Y-A$) on some key facts which can only be neglected at the risk of perilously obfuscating the policy problem.

The Role of Gold and Exchange Reserves

If no loans, investments, or repayments are received from abroad, there cannot be any negative B unless someone in the country is willing to give up foreign balances or other foreign assets. Ordinarily, the monetary authorities are the only willing sellers of foreign balances (or gold). If they do not sell, or have none to sell, the import surplus no longer exists; the real problem is not how to improve the trade balance, but whether to avoid its "automatic" improvement by the operation of "cruel" market forces—and how to make the unavoidable correction of the trade balance least painful or least harmful to the economy.

In a free market for foreign exchange—with no rate-pegging, rate-fixing, or rationing controls— there would surely evolve exchange rates at which all excess demand for imports is eliminated. One may ask *how*—by what forces and strains and stresses—this depreciation of the currency would succeed in balancing trade, but one cannot doubt that it would. A continuing import surplus, in the absence of autonomous capital imports, presupposes a policy of pegging the exchange rate by selling gold or foreign exchange; it disappears when that policy is discontinued.

The Role of Credit Creation

If no loans, investments, or repayments are received from abroad,

[28] *Ibid.*, p. 275.

there cannot be any negative B unless someone in the country is using previously inactive domestic cash balances (which is not likely to go on for very long), or new currency is printed, or the banking system, with the active support of the monetary authorities, engages in a continuing expansion of its loans-and-securities portfolio. If this continuing supply of domestic funds is not explained, one cannot understand how "propensities to absorb" can ever lead to absorption in excess of income.

The continuing supply of new bank credit need not be a continuing net increase in the supply of money. When the monetary authorities sell foreign exchange from their reserves, the domestic money (bank deposits) that is paid for it is canceled. The expansion of the loans-and-securities portfolio of the banks merely recreates the bank deposits canceled by the purchases of foreign balances from official reserves. To put it differently, the current credit expansion finances the current "excess absorption" by consumers and investors as well as the purchase of the foreign exchange that it requires.

Without continuing dishoarding or bank credit expansion, the negative trade balance could not continue. Every day of excess imports would bring a further reduction in the money supply of the people and, inevitably, a decline in absorption. A persistent import surplus, in the absence of autonomous capital imports, presupposes a policy of enabling the banking system to expand credit; it disappears when that policy is discontinued.

The possibility of credit expansion, incidentally, besides being a prerequisite of the maintenance of a negative trade balance and of any deterioration of the trade balance, is also essential in other phases of the operation of Alexander's model. In particular, the working of the idle-resources effect may depend on it. While some increase in employment can usually be financed by hitherto inactive liquid funds, by and large it takes new bank money to do this job.[29]

Assumptions about the Supply of Money

Nothing can be said about the effects of a devaluation unless exact specifications are made regarding the supply of money and credit and

[29] Alexander's attempt to combine his two income effects of devaluation in one expression and to treat them alike suffers not only from the defect that the terms-of-trade effect on the trade balance does not operate solely via income, but also that "finance" is no prerequisite for it. An increase in real income produced by the idle-resources effect must be accompanied by an increase in money income and money flow; on the other hand, a change in real income produced by the terms-of-trade effect may be merely a matter of relative prices and need not be reflected in a change in money income and circulation. This difference, neglected by Alexander, may be significant and has even its policy aspects, because inelasticity of the supply of money may be part of the monetary policy of a country or a built-in feature of its currency system, which would largely inhibit the operation of the idle-resources effect.

the fiscal policy of the government. There seems to be a tendency in the "New Economics" tacitly to regard the supply of money as a dependent variable rather than as a policy variable. In the "very old economics," where models of an unmanaged gold standard still had some applicability, the supply of money could be treated as a dependent variable. But when everybody has views on how the supply of money "ought" to be managed, and when in fact almost every government in the world does manage the supply of money, one may reasonably expect economic analysts to be explicit on this point and to state what happens under the various monetary policies which a government may choose to pursue.

On some occasions Alexander follows this good practice; for example, in discussing the cash-balance effect he first stipulates that "the money supply is inflexible." But in many places he fails to make such stipulations.[30] Indeed, he later returns to the cash-balance effect and calls it transitory because "the money supply may *respond* to the increased demand for cash balances."[31] As economists we should, I submit, make a clear distinction between a "response" explainable in economic terms (such as an increase in quantities of product supplied in consequence of increased effective demand reflected in higher prices and in greater profitability of an increased output) and a "response" explainable in political terms (such as an increase in the quantity of money—associated with increased government expenditures, reduced reserve requirements, increased open-market purchases by the central bank, etc.—either in consequence of political pressures or in anticipation of economic, social and political repercussions considered to be undesirable by the political powers). An economic response will be treated as a dependent variable; a political response should be treated as a policy variable and enumerated among the "special assumptions."

To assume tacitly, as is often done, that the money supply will "respond" to an increased demand for credit (to finance increased wage payments and increased foreign payments) may deprive an analysis, such as that of the effects of devaluation, of much of its meaning. To be sure, where the purpose of devaluation is to stimulate employment through the stimulation of exports, it will be the policy of the authorities to help supply the additional credits that are demanded. Even in this case the analyst should state what policy is assumed. But where the purpose of devaluation is to reduce or remove an excess demand for foreign money (that is, with regard to the external balance, an excess supply of domestic money), a policy of supplying the credit demanded

[30] *Op. cit.*, pp. 270, 273, although he speaks there repeatedly of "rising money incomes and rising prices."

[31] *Ibid.*, p. 274. Emphasis supplied.

to replace the excess demand that was squeezed out by the devaluation is not very consistent—even if it should be politically unavoidable.[32]

VI. *Comparing the Two Approaches*

Given and Unchanged Parameters

The reason given for advancing the aggregate-spending approach was that its predecessor the relative-prices approach suffered from incurable deficiencies. The basic trouble of the latter is that it works with price elasticities which presumably are given and knowable, but actually are neither —and are even changed as a result of the very devaluation effects which they are supposed to determine.

The new approach assigns strategic importance to spending propensities. Since these spending propensities are supposed to determine the effects of devaluation upon the trade balance, the impression is created that a, the marginal propensity to absorb, is both given and knowable. Actually it is neither; indeed, we have every reason to believe that a is not stable over time and that it may change not only with the mood of the time but also momentarily according to the circumstances of the situation. Although called a "propensity" to absorb income, it contains both intentional and unintentional reactions, including unintended investment or disinvestment in inventories, which sometimes may offset the effects of intentional reactions; it comprises government expenditure (inclusive of public capital expenditure), which is not a function of income but an independent variable that can be administered in a direction opposite to that of changes in income; even in so far as it refers to private actions, it may be significantly influenced by monetary and fiscal policy; and, finally, it may be substantially changed as a result of the very devaluation the effects of which it supposedly determines.

Hence, what was said about the "elasticities approach," namely, that "the statement that the effect of a devaluation depends on the elasticities boils down to the statement that it depends on how the economic system behaves,"[33] may with equal justification be said about the income-absorption relation. For, after all, the devaluation effects upon income and absorption, including the supposedly given "propensities to absorb," depend "on how the economic system behaves"—and, we may add, on how it is made to behave by monetary and fiscal policies.

From the point of view of stability over time it is hard to say which of the parameters are less reliable as indicators of the effects of devalua-

[32] Even in this case a policy of devaluation may be adopted with the idea of taking advantage of lags and of gaining a breathing spell between devaluation and re-inflation.

[33] *Op cit*, p 264.

tion on the trade balance—the price elasticities or the spending propensities. From the point of view of changeability in the very process the outcome of which they help determine, the spending propensities are probably less reliable than the price elasticities. And from the point of view of malleability through public policy, one probably should regard the price elasticities as the tougher factors to deal with, and the spending propensities more subject to the influence of (monetary and fiscal) policy—which means that in the last analysis not given propensities but chosen policies will determine the outcome.

Foreign Supply and Demand Conditions

An explanation of the volume, composition, terms, and balance of trade between nations can hardly be regarded as fully convincing if it takes account of the conditions in only one of the nations concerned instead of considering all parties involved. The relative-prices approach attempts to satisfy this precept by including the supply and demand conditions in foreign markets among the determining factors. In particular the elasticities of foreign demand for the exports and of foreign supply of the imports of the devaluing country are assigned important roles.

The aggregate-spending approach makes no such provision, at least not explicitly. It attempts to deduce the devaluation effects on the trade balance solely from the effects upon national income and absorption in the devaluing country. Since the "resulting" change in the trade balance is necessarily also a change, by the same amount though with opposite sign, in the trade balance of the trading partner—perhaps the rest of the world—one wonders how this change is imposed, so to speak, on the latter, regardless of the magnitudes of their spending propensities, etc. If only the ΔY and ΔA of the devaluing country were to determine the outcome, would this not imply that in the other countries changes in income and absorption would be "dictated" by a change in the trade balance, instead of the other way around?

Alexander's analysis is silent on this point. An enterprising builder of aggregative models might set out to construct a two-country model embodying the income-absorption relations based on the spending propensities in both countries affected by the change in foreign exchange rates. But I am not convinced that this would be a worth-while undertaking. It is probably more expedient to assume that "the foreign country" is the rest of the world, that the world-wide income and absorption effects of the devaluation of the one currency are so widely dispersed as to be negligible, and that therefore the elasticities of foreign demand and foreign supply are not sufficiently altered to lose

their determining force on the outcome.[34] But this solution would obviously restore the elasticities approach to at least half its former role in the analysis of devaluation.

Price Elasticities in the Spending Approach

As a matter of fact, this restoration of relative prices and price elasticities to a strategic position in the model is not left to its reconstruction by future renovators; price elasticities have been allowed to continue all along, though inconspicuously, to do their job under the new regime. Supposedly banished under the aggregate-spending approach, they have in fact played important roles in Alexander's analysis.

At some points the elasticities work behind the scene. For example, whether there can be an idle-resources effect of devaluation depends on whether the production and sale of export goods can be expanded, hence, on elasticities of domestic supply and of foreign demand; but this is not explicitly said. At other points the elasticities are clearly visible on the stage. For example, whether a direct devaluation-effect upon absorption will result in a transfer of resources or in unemployment, depends on "how the economy responds to price incentives,"[35] or on the "price differential between the foreign and the domestic markets" and on "the substitutability of domestic goods for imports in consumption, and of resources as between the production of domestic goods and exports."[36] At one point at least, the role of price elasticities is dominant: in the terms-of-trade effect. For it is impossible to come to any conclusion concerning the effects of devaluation upon the terms of trade except on the basis of an examination of the relevant elasticities of supply and demand.

Alexander would probably deny none of this. For, although he regards aggregative analysis as "a more fruitful line of approach," to be adopted in lieu of "the more traditional supply and demand analysis,"[37] he concedes that "supply and demand conditions, in the sense of partial elasticities, may be useful tools in this [income-absorption] analysis."[38] His objection is to discussions in terms of "total elasticities" and he believes that it is "total elasticities for which the conventional formulas alone are valid."[39]

[34] This suggestion was made by Michael Michaely, *Devaluation and Dual Markets under Inflation with Direct Controls*, a doctoral dissertation submitted to Johns Hopkins University, January, 1955.

Conclusion

The upshot of all this is that relative prices and elasticities were not really discarded in the analysis of devaluation effects; and that aggregate spending and propensities by themselves cannot possibly do the explanatory job that was assigned to them. Neither of the two "alternative" sets of tools can be spared; both are needed.

Alexander, I am afraid, has confused his readers by presenting the new approach as a substitute for the old. If clearly presented as complementary to the old, and properly amended, the new analysis can be helpful. The new tools fashioned by Alexander cannot replace the old tools of "conventional analysis"; but they can, after some substantial reshaping, increase the usefulness of the latter.

It is the habit of innovators to disparage the old ways of doing things; it is the duty of critics to appreciate the value of the new without depreciating the value of the old. In trying to pare down the exaggerated claims of the innovator they are sometimes overly critical of the new ideas. Lest I have erred in this direction, I should like to end by paying my respect to Alexander's innovating enterprise and to his contribution to the development of international trade theory. A contribution it is, and an especially meritorious one where it gives scope to the roles of both aggregate spending and relative prices.

---

ander must have mistaken them for operational devices or for mere *ex post* relationships. If he means "*ex post* elasticities" when he says "total elasticities," he surely misunderstands most of those who have argued in terms of price elasticities I, for one, have always had *ex ante* elasticities in mind.

THE THEORY OF FLEXIBLE EXCHANGE RATES

By E. VICTOR MORGAN*

Until quite recently, it was generally believed that a fall in the exchange value of a currency would improve the balance of trade and worsen the terms of trade of the country concerned. During the interwar period, when there was a growing consciousness of the difficulties of reducing the domestic price level through a deflationary monetary policy, it became quite fashionable to advocate flexible exchange rates as the best means of maintaining international balance. Underlying this preference was the belief, not only that depreciation would be effective in correcting an adverse balance, but that it would do so at a cost (in the deterioration of the terms of trade) which would be less than the cost of other forms of adjustment.[1]

The growth of interest in exchange flexibility as a policy led naturally to a parallel development of theoretical studies. The regrettable thing, in the opinion of the present writer, is that these studies concentrated on the concepts of elasticity of supply and demand, and largely ignored the fundamental developments in the pure theory of foreign trade, which were going on at the same time.[2] The main object of this paper will be to submit that results based on these elasticities are subject to severe limitations in theory and are misleading in their policy implications. First, however, it is necessary to give a very brief summary of the theory which it is proposed to criticize.[3]

The basic concepts are four elasticities: the home elasticity of demand for imports (ε_i), the foreign elasticity of supply of imports (η_i),

* The author is professor of economics in the University College of Swansea, Swansea, Wales.

[1] That is, the idle resources associated with deflation, and the loss of efficiency in the use of resources resulting from direct import restrictions.

[2] Notably the "proportions of the factors" analysis developed by Heckscher, Ohlin and Samuelson: *e g*, E. F. Heckscher, "The Effect of Foreign Trade on the Distribution of Income," *Ekonomisk Tidskrift*, 1919, XXI (2), 1-32, trans in H S. Ellis and L A. Metzler, ed., *Readings in the Theory of International Trade* (Philadelphia, 1949), pp. 272-300; B. Ohlin, *Interregional and International Trade* (Cambridge, Mass, 1933); P. A. Samuelson, "International Trade and the Equalisation of Factor Prices," *Econ. Jour.*, June 1948, LVIII, 163-84; *idem*, "International Factor-Price Equalisation Once Again," *Econ. Jour.*, June 1949, LIX, 181-97.

[3] I shall not attempt to give a full list of the many papers in which these matters are discussed, though a number of them will be cited later.

the foreign elasticity of demand for exports (ϵ_e) and the home elasticity of supply of exports (η_e). Considering only the trade balance, and starting from a balanced position, it has been shown that a small proportionate fall in the exchange rate (K) will produce a favorable balance, as a proportion of the original value of exports, of

$$K \cdot \frac{\epsilon_i \epsilon_e (1 + \eta_i + \eta_e) + \eta_i \eta_e (\epsilon_i + \epsilon_e - 1)}{(\epsilon_i + \eta_i)(\epsilon_e + \eta_e)}$$

This must be positive if the sum of the two demand elasticities is greater than unity, and it may be positive, even if the sum of the demand elasticities is less than unity, provided that the supply elasticities are sufficiently small.

The corresponding formula for the deterioration of the terms of trade is

$$K \cdot \left(\frac{\eta_i}{\epsilon_i + \eta_i}\right) - \left(\frac{\epsilon_e}{\epsilon_e + \eta_e}\right) = K \left(\frac{\eta_i \eta_e - \epsilon_i \epsilon_e}{(\eta_i + \epsilon_i)(\eta_e + \epsilon_e)}\right).$$

This will be positive, and the terms of trade will turn against the depreciating country if $\eta_i \eta_e > \epsilon_i \epsilon_e$, that is if the product of the supply elasticities exceeds the product of the demand elasticities. Mrs. Robinson's condition ($\frac{\eta_e}{\epsilon_i} > \frac{\epsilon_e}{\eta_i}$ in our notation) also follows from this formula.[4]

Each of these elasticities is a derived concept. For example, a fall in the price of an imported good would lead both to an extension of demand and to a contraction of domestic supply (if it were also produced at home). The resulting extension of the demand for imports is made up of the sum of these two changes. In order to set out the relationships concisely let D = volume of demand, S = volume of supply, and Q = volume of imports (all before the price change); let h = the home country and w = the rest of the world. Then we have:

$$\epsilon_i = \frac{\epsilon_{hi} D_{hi} + \eta_{hi} S_{hi}}{Q_i}$$

$$\epsilon_e = \frac{\eta_{we} S_{we} + \epsilon_{we} \cdot D_{we}}{Q_e}$$

$$\eta_i = \frac{\epsilon_{wi} D_{wi} + \eta_{wi} \cdot S_{wi}}{Q_i}$$

$$\eta_e = \frac{\eta_{he} \cdot S_{he} + \epsilon_{he} \cdot D_{he}}{Q_e}$$

[4] Joan Robinson, *Essays in the Theory of Employment* (London, 1937), p. 21 n

The condition for a deterioration of the terms of trade as a result of depreciation can then be written:

$$\frac{\epsilon_{wi} \cdot D_{wi} + \eta_{wi} \cdot S_{wi}}{\epsilon_{hi} \cdot D_{hi} + \eta \epsilon_{i} \cdot S_{hi}} > \frac{\eta_{we} \cdot S_{we} + \epsilon_{we} \cdot D_{we}}{\eta_{he} \cdot S_{he} + \epsilon_{he} \cdot D_{he}}$$

So far as the quantitative weights are concerned, a high value on one side of this expression is very likely to be associated with a high value on the other. As for the ratios of the respective elasticities, there seems no a priori reason for supposing that one need be higher than the other. Apparently depreciation would tend to raise the prices of both imports and exports in relation to those of nontraded goods, but the formula gives us no reason to suppose that one would necessarily rise more than the other.[5]

It thus appears that depreciation may, according to the structure of the economies concerned, cause both the terms of trade and the balance of trade to move either way. Moreover, since the change in the terms of trade depends on the ratios of the elasticities, while that in the balance of trade depends on their absolute magnitudes, there is no necessary relationship between them. So far from moving, of necessity, in opposite directions, it is quite conceivable that both might improve or both deteriorate as a result of depreciation.

Writers who have treated the subject in this way have generally concentrated on the trade balance alone, ignoring invisible items, capital movements, speculation and the hoarding of foreign currencies. In such a model, a tendency for the balance of trade to deteriorate[6] as a result of depreciation implies a situation of unstable equilibrium in the foreign exchange market. No one has assumed that the markets for the goods entering into trade are in unstable equilibrium, so we have the strange phenomenon of a series of apparently stable goods markets producing an unstable currency market, even though the currencies concerned can be used for no other purpose than the purchase of goods. To one who was brought up on the relatively simple notions of traditional economic theory, all this seems more than a little odd. A number of estimates of

[5] Mrs. Robinson gives reasons why depreciation should lead to an adverse movement based largely on the generalization that, "Any one country plays a more dominant rôle in the world supply of those goods which it exports than it plays in the world market for those things which it imports" (*op. cit.*, p. 219). I doubt if this is universally true, but it is certainly true of some countries; and where it is true, our formula suggests that a deterioration in the terms of trade is a likely consequence of depreciation.

[6] In a model which excludes capital movements, there can be no actual deterioration of the balance. The only meaning which can be attached to the term is the creation of the excess of demand for the foreign currency over its supply.

demand elasticities have been published.[7] Most of them have been surprisingly low, some so low as to cast grave doubts on whether depreciation would be effective at all. The result has been something of a revulsion against the policy of flexible exchange rates. If one accepts both the statistical estimates and the theory underlying them, it is hard to avoid the conclusion that, if flexible rates worked at all, they would do so only at the cost of very violent and disturbing fluctuations. This pessimistic conclusion is by no means out of keeping with the general climate of opinion which is prevalent in some quarters. If one cannot correct an adverse balance by reducing domestic prices for fear of unemployment, industrial strife and bloody revolution; and if exchange depreciation is ineffective, then the only way must be through direct controls. Those who, on other grounds, are inclined towards direct controls can thus take some satisfaction in this apparent vindication of their beliefs.

There have been a number of refinements of the theoretical concepts, some of which will be mentioned later, and the statistical estimates have been subjected to devastating criticism by G. H. Orcutt.[8] There has been little attempt, however, to relate the new apparatus to the theory of international values, and it is when viewed in this light that the whole elasticity approach appears, to the present writer, untenable.

The basic weakness lies in the use of the concept of elasticity itself. Its original and proper use is, of course, to describe a simple functional relationship between volume of sales and price. This implies that the commodity must be sufficiently homogeneous to be measured in physical units, and that all other relevant variables (including money income and the prices of all other goods) must be unchanged. These are the familiar assumptions made in the partial equilibrium analysis of supply and demand for a single good, but they are far removed from what actually happens in the course of international trade.

For a full picture of the adjustment process we need to go behind the goods markets to the factor markets, and to follow the sort of analysis made familiar by Ohlin.[9] Suppose that we have two countries, A and B, endowed with factors of production, $f_1, f_2, \ldots f_n$. Call the currency of A dollars and that of B sterling. Take the amount of each

[9] *Op. cit.*, esp. pp. 28 *seq.*

of the factors which can be bought in A for $1 and find the respective prices of these amounts in country B. Convert these prices into dollars at any given exchange rate, and arrange the factors in ascending order of price. The resulting range might look something like the line $B_1B'_1$ in the diagram below, where each dot represents a factor of production. The corresponding A prices would be represented by the horizontal line AA′, since we have taken a dollar's worth of each factor as a unit of measurement. Now suppose the pound to depreciate against the
FIGURE 1

dollar. The immediate effect will be to produce an all-round proportionate reduction in the dollar prices of B factors. Instead of $B_1B'_1$ we shall have a range such as $B_2B'_2$. This is the fundamental impact effect of depreciation, a cheapening not of the goods, but of the factors of the depreciating country.

From the cheapening of factors, there naturally follows a cheapening of goods, but the relationship is by no means simple. It will become profitable to export some goods not previously exported, while some which were previously imported will be produced at home. There will also be changes in the relative importance of different goods both in the import and export lists. In the depreciating country there will be an increase in the demand for factors from the export industries and those producing goods competing with imports. Some factors, which are in elastic total supply or which can readily be drawn from other industries, will change little in relative price. Others, for which a strong demand is coupled with an inelastic supply, will rise sharply. Apart from the production functions of the expanding industries and the demand functions for their products, there are at least three influences on the availability of factors: the elasticity of their total supply, their

elasticity of substitution and the elasticity of demand for the products of other industries in which they are used.

Industries using a large proportion of those factors which remain relatively cheap will expand much; others which use a preponderance of factors which are rising sharply in price will have their expansion cut off at an early stage. Similar changes will be going on, in the opposite direction, in the countries which do not depreciate. There is thus a kaleidoscopic movement both among goods and among factors, which will come to an end only with a new general equilibrium of the whole system. All these changes are masked by the concept of an elasticity of demand for imports and exports as a whole.

All this is familiar ground to any undergraduate student of value theory, yet there has been no real attempt to reconcile it with the elasticity approach. Even Haberler, in one of the most closely reasoned expositions of the subject[10] assumes that "we have constructed a sort of average or aggregate curve; in other words we have demand and supply curves for a 'representative bale' of imports and exports" (p. 196). Most other writers do not discuss this aspect of the problem at all.

So far as I can see there is no way out of the difficulty. Any calculation of elasticities for a group of nonhomogeneous goods must measure the relationship between some sort of price index and some sort of index of quantity. No index number can take account of the entry of new goods into trade, or the disappearance of goods formerly traded, and whenever there are changes in the relative importance of different goods, there can be no uniquely right system of weighting. Yet these changes are the very essence of the international adjustment mechanism.

The elasticity of demand for a homogeneous good can be defined in terms of price and quantity which are independent of the statistical techniques used to estimate the elasticity. It is thus possible to conceive of a "true" elasticity and of various more or less close approximations to the truth given by different methods of estimation. With a group of nonhomogeneous goods, however, it is impossible to define elasticity except in terms of the particular methods of estimation which may be used. When we have the type of changes which are bound to occur in the course of international adjustment, none of these methods is uniquely right, and we cannot conceive of a true elasticity. When we use the words elasticity of demand (or supply) for imports (or exports) we quite literally do not know what we are talking about.

We can, of course, make the whole vexatious difficulty fly out of the

[10] G. Haberler, "The Market for Foreign Exchange and the Stability of the Balance of Payments," *Kyklos*, 1949, III (3), 193-218

window by constructing a simple model in which we assume only two traded goods, one homogeneous import and one homogeneous export. This procedure is of very limited usefulness. It rules out an essential part of the adjustment mechanism of the real world; the construction of the model itself presents some peculiar theoretical problems; and if it is simplified sufficiently to avoid these problems, it can be handled more easily and effectively by an analysis of stability conditions on the lines developed by Hicks than by the use of elasticities.[11] Nevertheless, a brief glance at such a model may be helpful.

First, suppose that we have only two goods, that they are both produced in each of two countries but also traded, and that trade proceeds by means of barter. It would, of course, be impossible for an actual adverse balance to arise. A potentially adverse balance would take the form of an excess of demand for oversupply of the imported good at the ruling market price, and this would tend to raise the price of the import in terms of the export good. This change would set up income, substitution and production effects. The substitution effect would cause a shift in demand in both countries away from the good which had risen in price, while the production effect would stimulate an increase of the supply of that good in both countries. Both these tendencies must be equilibrating, and only the income effect will be ambiguous in direction. The country which has suffered a deterioration in its terms of trade may be expected to consume less of the good in question as a result of its lower real income, while the country whose terms of trade have improved may be expected to consume more. Normally the two influences will tend to cancel one another out, but they would not do so if the good which rose in price were an inferior one for the citizens of one country, but not for those of the other. We thus reach the standard conclusion which applies to a similar situation in a single country; the markets will be stable unless there are very strong and perverse income effects. Since we have excluded money, we cannot have a balance-of-payments problem in this model. But one significant point arises: the correction of a potentially adverse balance involves, of necessity, a deterioration in the terms of trade.

We now introduce into our system what Hicks has called a "shadow money," a money which acts as a *numéraire* but which has none of the other characteristics of money and, in particular, cannot be hoarded. We suppose both our countries to have such a shadow money. There would seem to be nothing to determine the absolute level of prices, and an adjustment might take place either through the exchange market or through a change in goods prices. It can be shown, however, that so long as money can be used only for the immediate purchase of goods,

[11] J. R. Hicks, *Value and Capital* (Oxford, 1939), Pt. 1.

it is impossible to have an unstable exchange market associated with stable commodity markets.

To illustrate this, it is convenient to get rid of the production effect, which is bound to be equilibrating. We therefore assume two countries, A and B, each completely specialized on goods α and β, respectively, and having currencies *a* and *b*. Suppose that country A has a tendency to an adverse balance, and that the whole adjustment takes place in the exchange market, the domestic prices of each good in the country producing it being held constant. Constant domestic prices mark the situation in which, according to the elasticities formula, the demand elasticities have to be highest in order to insure stability.

A fall in the *a-b* exchange rate will make good β dearer in A, and so reduce the volume of imports and the demand for currency *b*. The exchange market will thus be stable unless the demand for the good α in B is so inelastic that the fall in its price there reduces the supply of currency *b* to an extent even greater than the reduction in the demand for it. But if money can be used only for the immediate purchase of goods, a reduction of the supply of *b* in the exchange market implies that the citizens of B must be spending correspondingly more of their own currency on their own commodity. Hence if the supply of currency *b* is reduced by more than its demand, it follows that the demand for good β from citizens of B increases by more than its demand from citizens of A decreases. The rise in the relative price of good β, brought about by depreciation, has increased the excess demand for it, and the market for the two goods, in the two countries together, is in unstable equilibrium.

The assumption of a shadow money has only a very limited usefulness, yet the transition from a shadow money to a real money is by no means without its difficulties. An essential characteristic of real money is that it can be hoarded, and changes in the propensity to hoard will involve changes in aggregate money income.[12] It thus appears self-contradictory even to set up a model involving a real money which does not take account of fluctuations in income. Fluctuations in domestic income are, of course, bound to occur when an actual change in the trade balance takes place, unless that change is offset by an equal and opposite change in some other component of national expenditure, and this has been realized from the beginning by exponents of the elasticity approach.

[12] Fluctuations in aggregate money income will be associated with fluctuations in real output if they occur at less than "full employment level" and with increases or decreases in inflationary pressure if they occur at above that level. Most writers have assumed idle resources and concentrated on the real fluctuations, but here it seems better to adopt the more general formulation.

The treatment of these fluctuations has given rise to some differences of opinion. Mrs. Robinson[13] regards them as purely a consequence of changes in the foreign balance, and so contends that they can be ignored in considering the direction, though not in considering the extent, of the change which depreciation will cause. Harberger, on the other hand, demonstrates that a change in real output would occur in his model, even if there were no change in the foreign balance, if depreciation led either to a change in investment or to a change in the propensity to hoard.[14] For his model, which assumes constant prices, Harberger finds that the critical value for the sum of the two demand elasticities is not unity, but one plus the sum of the two marginal propensities to import.

The existence of income fluctuations does not necessarily prove fatal to the elasticities approach. Both Harberger and Stuvel[15] have produced elegant and relatively simple mathematical systems which incorporate income fluctuations into the analysis. Both, however, depend upon the existence of marginal propensities to import which are stable enough to be used as parameters. To test the validity of this assumption we need to ask two further questions. Will the price changes resulting from depreciation create changes in the structure of the economy which are likely to alter the relationship between "real income" and imports? And will the changes in imports and exports resulting from a change in income themselves set up further price changes independent of the initial ones? The use of marginal propensities to import in conjunction with elasticities is only justified if both these questions can be answered in the negative, whereas I suggest that the answers to both should be in the affirmative.

We have already suggested that the essence of the adjustment mechanism is a change in relative factor prices leading to a change in the relative importance of different goods in the import and export lists. It would be very surprising if goods which entered into or disappeared from trade responded to changes in income in just the same way as others, and if goods which diminished in importance responded in just the same way as those which increased in importance. Import lists will be different after depreciation from what they were before, and it is only to be expected that they should respond differently to changes in real income.

Moreover, the process of adjustment outlined above involves changes in the relative prices of factors, *i.e.*, a redistribution of income, in both countries, and it is unlikely that the marginal propensity to import

[13] "The Foreign Exchanges," *op. cit.*, pp. 183-209.

[14] A. C. Harberger, "Currency Depreciation, Income and the Balance of Trade," *Jour. Pol. Econ.*, Feb. 1950, LVIII, 47-60.

[15] G. Stuvel, *The Exchange Stability Problem* (Oxford, 1951).

would remain just the same after such a redistribution as it was before.

The changes in factor prices will change both the position and the shape of the cost curves (in each country's own currency) of the domestic industries which compete with imports. This will mean that these industries will react differently from before to changes in demand associated with income changes. Unless we confine ourselves to the assumption of constant domestic prices, we have to consider the secondary price changes (as between imports and domestic goods) which arise from changes in demand which are, themselves, consequences of changes in real income, and these secondary price changes will be different after depreciation from what they would have been before.

Finally, changes in relative factor prices will change the import content of exports. The marginal propensity to import of one country is reflected in the exports of another, and changes in income and imports will therefore be reflected back from one country to another in a different way after depreciation.

I suggest, therefore, that the use of ordinary marginal propensities to import in this context is a simplification which is very likely to be misleading. I do not doubt that a formal solution of these problems could be obtained by constructing a much more elaborate model with a sufficient number of new propensities and elasticities, but the model would probably produce so many equations that an electronic calculator would be needed to solve them. Even then, I suspect, it would only tell us that everything depended on everything else.

So far we have been concerned with two objections to the elasticity approach; that it is impossible to define elasticities which take account of the changes in the composition of import and export lists, which are the essence of the adjustment mechanism; and that it is very difficult, if not impossible, to take adequate account of the changes in income which are bound to be associated with depreciation. A third and final objection is that depreciation is likely to lead to shifts in supply and demand curves, independent of those which may occur through changes in income, as a result of changes in the relative prices of imports, exports and nontraded goods.[16]

To illustrate these effects, suppose that a country, which we call A, increases its exports of motorcars to another country, B, as a result of depreciation. There will be a decrease in the demand for "motor-making" factors in B, and this will reduce their relative price, and cause a shift to the right in the supply schedules of other B goods

[16] This point has been made by R. F. Kahn, "Tariffs and the Terms of Trade" in *Rev. Econ. Stud.*, 1947-48, XV (1), pp. 14-19; and C. Kennedy, "Devaluation and the Terms of Trade," *ibid.*, 1949-50, XVIII (1), pp. 28-41.

which use the same sort of factors as the motor industry. This shift to the right in the total supply schedules for such goods is likely to be associated with a shift to the right in the export supply schedules of those of them which are exported. It is also likely to lead to a fall in the domestic prices of these goods, whether exported or not, and this in turn will lead to a shift in the B demand curves for imports. Where the income effect of such a change predominates there will be a shift to the right in the demand curve for imports and when the substitution effect predominates, there will be a shift to the left in the demand curve for imports. Thus the increase in the volume of A exports as a result of depreciation will cause shifts in both the demand curve for imports and the supply curve for exports in country B. Similar changes in factor prices, though in the opposite direction, will be set afoot in country A, so that the position of all four curves will be affected. Only if all these shifts are so small as to be negligible, will the true elasticities of supply and demand be relevant to the situation created by depreciation. While this might be so for a country whose foreign trade forms only a very small proportion of its national income, it is very unlikely to be so for a country such as Great Britain.

It may be said that the whole of our criticism of the elasticity formulae boils down to the statement that they depend on a number of simplifying assumptions, and that a similar accusation could be made against almost any proposition in economic theory. But the vital question in the application of theory to policy is whether the things which have been left out in the process of simplification are important or unimportant. Indeed a large part of the art of political economy lies in knowing what to ignore. In this case, if one accepts the factor-proportions analysis on which the pure theory of foreign trade depends, it seems that the simplifications required in order to validate the elasticity formulae are of the utmost importance, and that policy conclusions based on the formulae are far more likely to be wrong than right.

Up to now the argument of this paper has been purely negative, but it would be unfair to urge the rejection of the elasticity approach without at least trying to put something in its place. The simple theoretical apparatus, which is all I have at my command, cannot reach the same precision as appeared to have been reached in the elasticity formulae, but I think it can say a little which is of use as a general guide to policy. We can use the results which emerged from our simple models as a starting point. In these models, we found that, so long as money can be used only for the immediate purchase of goods, it is impossible to conceive of an unstable exchange market unless the market for at least one of the traded goods is also in unstable equilibrium. We also found that

if the goods markets are stable, depreciation, carried to a sufficient extent, must be capable of restoring the trade balance, though at the cost of a deterioration in the terms of trade.

For the present we concentrate on the trade balance, though it will be suggested that our theory also has relevance to the broader problem of the balance of payments. We first distinguish between the various circumstances which may cause the balance of trade to become unfavorable. For this purpose we need criteria of external and internal balance, and it is convenient to start from a point of "full employment." We define full employment as the level of employment which will maximize home-produced national income at constant prices, the value added by the setting to work of a marginal man from among the unemployed being just offset by the loss of value resulting from the frictions and dislocations of "overfull employment." The relationship between income and expenditure must obviously be an *ex-ante* one, and I take as my criteria of equilibrium that planned expenditure (public and private, for consumption and investment) on domestic goods and services plus expected sales abroad should equal the value, at current prices, of full-employment output; and that planned expenditure on foreign goods and services should equal expected sales abroad. If these plans and expectations were fulfilled, they would result in the maintenance of full employment and a neutral trade balance. We shall confine ourselves to the short period, so that we need not concern ourselves with the secular growth of full-employment output. Also, purely in order to simplify the exposition, we shall speak of two countries only, though these can be interpreted as "home" and "the rest of the world."

We can now distinguish five types of departure from equilibrium which may be, and at times have been, of great practical importance: (a) Where expected sales abroad cannot be made because international prices are out of line; (b) Where expected sales abroad cannot be made because of a fall in the foreign demand for one or more export goods; (c) Where there is inflation at home; (d) Where there is depression abroad; (e) Where there is stability in internal expenditure and a neutral trade balance, but with large idle resources. It is proposed to glance at each of these situations in turn.

Situation (a). We suppose that the home country is enjoying full employment, and is in *ex-ante* equilibrium in the sense described above, but that prices are such that expected sales abroad cannot be made. There will thus be a debit balance in the international account, total expenditure on domestic products will fall below the current value of full employment output, goods will remain unsold, and unemployment will appear. This primary fall in employment would tend to set up a

multiplier effect, leading to secondary falls in employment and in home-produced national income; the reduction of national income would tend to reduce the demand for imports and (together with the opposite effect in the foreign country) would tend to restore the trade balance. Normally, however, these income effects will not be sufficient fully to restore equilibrium.

We now suppose that the monetary authorities of the home country allow its currency to depreciate to the point (if such a point exists) which would restore the trade balance with a full-employment level of real income. As exports increase and domestic spending is diverted from imports to home-produced goods, national income will rise again. The income effect mentioned above, though it will continue to operate in an equilibrating direction so long as it exists, will grow progressively weaker and finally, with a return to full employment, will disappear. The problem is, therefore, whether there is a new exchange rate lower than the old which will maintain equilibrium in the trade balance when the old level of home-produced real income is restored.

Here the reasoning of our simple model of pages 285-86 can be of use. If the monetary authorities both of the home and the foreign country were to take steps to maintain the total money expenditure of their citizens at the level at which it was running before the departure from equilibrium (*i.e.*, equal to the value at current prices of full-employment output) we reproduce artificially the essential condition of our simple model. A decrease in expenditure in one sector of the economy must have its counterpart in an equal increase in expenditure somewhere else, just as it would if money could only be used, as in our simple model, for the immediate purchase of goods. In particular, any decrease in expenditure on foreign currency in the exchange market must be associated with an equal increase in expenditure on domestic products.

The impact effect of depreciation will be a cheapening of home goods in terms of foreign ones, a reduction in the volume of imports and a reduction in the demand for foreign currency. The exchange market will be stable unless this reduction in demand is associated with an even greater reduction in supply. But a reduction in the supply of foreign currency in the exchange market must mean that foreigners are spending more on their own products. This increased expenditure would be diffused over a great variety of products, and there might be most complicated substitutions between one and another, but it still remains true that there must be at least one good for which the increase in foreign demand is greater than the reduction in demand from the home country. In other words, there must be at least one good for which an increase in relative price would increase excess demand. We

thus reach the conclusion that a sufficient measure of depreciation must be effective in restoring the trade balance unless at least one of the product markets is in unstable equilibrium.

This conclusion is independent of whether traded goods are produced in both countries or not, and its validity does not depend on the assumption of constant prices made in our simple model. If depreciation produced a secondary rise in the domestic price of the home product, this would mitigate any fall that might occur in the supply of the foreign currency (since a fall can only occur if foreigners spend less on imports the lower the price) but it would in no way alter the fact that, if such a fall does occur, it must be associated with an increase in foreigners' spending on their own products. If there is a secondary fall in the price of the foreign products, it follows a fortiori that an increase in total expenditure on them must produce an increase in excess demand.

The same conclusion must obviously hold, if money expenditures are not maintained at a constant level, so long as expenditure in the home country does not increase and that in the foreign country does not fall below its equilibrium level as a result of depreciation. There is no obvious reason why foreign expenditure should fall below its equilibrium level,[17] but that of the home country might rise above it if depreciation brought claims for increased wages or if there were induced investment. It would, therefore, be necessary for the monetary authorities of the home country to prevent money expenditure from rising above its equilibrium level, and for the trade unions to refrain from pressing claims for wage increases which would make it impossible to regain full employment with this level of expenditure. On the other hand, the government could safely take the steps to offset any reduction in money expenditure and mop up any idle resources which might appear during the transition period.

This analysis is more general than the elasticity formula, for it can be applied to the whole foreign account. As long as the markets for services and assets, as well as goods, are stable, and as long as expenditure on all items and not merely on goods, is held constant, depreciation must correct not only the trade balance but the balance of payments as a whole.

How much importance we attach to this conclusion depends on how much confidence we have in the stability of the markets concerned. Experience affords very strong grounds for believing that the markets for services and for most forms of goods are stable. Economic analysis

[17] The unfavorable balance for the home country would be a favorable balance for the foreign country, and would tend to raise its income above the equilibrium level; the elimination of the balance by devaluation would thus only reduce foreign income to its equilibrium level.

and policy are both based on this assumption, and if we regulate our internal affairs satisfactorily on the assumption that we are dealing with stable markets, it seems only reasonable to make the same assumption in framing international policies.

On the other hand, the markets for commodities with low storage costs, real estate, stocks and shares, and currencies for hoarding are subject to periods of speculative instability, though these periods are generally brief. It is, therefore, quite possible that depreciation may set up price expectations in some of these markets which will lead to a period of instability, and if the latter is sufficiently strong, it may lead to instability in the exchange market as a whole. This is a strong argument against completely free exchanges, and in favor of an exchange equalization account which can be used to combat speculation. In my judgment, however, it does not seriously reduce the likelihood that, in the situation outlined above, an appropriate amount of depreciation will ultimately serve its purpose.

We can now dispose comparatively briefly of the other situations outlined above.

Situation (b). In this situation we suppose the same *ex-ante* equilibrium as in (*a*) but that the trouble with the trade balance arises not from general prices, but from a fall in the foreign demand for a particular export. This may be supposed to arise either from a change in tastes, from a change in foreign techniques which robs an export industry of its comparative advantage, or from the imposition or raising of a foreign tariff. The income effect will be as in situation (*a*) but there will also be a fall in the relative price of the export good concerned, which will have secondary repercussions on the whole structure of prices. Again, however, the maintenance of total money expenditure at an equilibrium level together with an appropriate amount of depreciation will restore the balance as long as the goods markets are stable.

Situation (c). This situation is very different from either of the two previously discussed. Here we suppose that planned expenditure on domestic goods plus expected sales abroad exceeds the current value of full-employment output. If domestic plans are carried out, expected sales to foreigners cannot be realized, not for lack of demand but because the goods will not be there to sell. If depreciation did succeed in luring some goods from the home to the foreign market, the only result would be that domestic plans would become incapable of fulfilment, and the attempt to fulfill them could only drive up prices, thus tending to nullify the effects of depreciation. The only way to cure this situation is to bring about a reduction in domestic spending plans; any revision of these plans which resulted from depreciation would be more likely to be in an upward than a downward direction, and

depreciation in these circumstances would be worse than useless.

Situation (d). In this situation we suppose that the home country starts from a position of equilibrium as in (*a*), but that sales fall short of expectations because of a fall in employment and incomes abroad. This will produce domestic income effects as in (*a*), but the situation will be more complicated because any reduction in the home demand for imports will be "reflected back" through a further fall in foreign income and in the foreign demand for exports. There would be a similar disequilibrating effect associated with depreciation. So far as depreciation reduces the home demand for imports or pushes exports in substitution for foreign produced goods, it will depress foreign income and bring about a secondary reduction in the foreign demand for exports. The full analysis of this situation is very complicated. It is clear, however, that (since we can no longer assume that foreign expenditure is maintained at the equilibrium level) the argument applied to situations (*a*) and (*b*) is not valid here. It is by no means certain that there is any exchange rate which will restore the balance of payments consistently with the maintenance of full employment at home. Even if such a rate does exist, depreciation will do its work only at the expense of complicating the stabilization program, of the foreign country.

Depreciation does not seem an appropriate remedy here. The best policy is clearly for the government to offset the fall in exports by creating additional spending at home (thus maintaining equality between actual spending and the value of full-employment output) and to meet the resulting foreign deficit from reserves. This is what reserves are for, and a country with adequate reserves should be willing to see them drawn on heavily in such a situation. If reserves are so small as to make some restriction of imports essential, then it would be better to bring it about directly than to rely on the uncertain working of depreciation.

Situation (e). This is Mrs. Robinson's "beggar-my-neighbor" case. One way of posing this is, "will depreciation turn a neutral balance into a favorable one on the assumption that there are no changes in spending except those following from the act of depreciation itself?" If we assume, with Mrs. Robinson, that depreciation will affect total domestic spending and home-produced real income only through changes in the trade balance, then the reasoning of (*a*) will apply, and we should expect depreciation to produce a favorable balance. If we take account, with Harberger, of the changes which are likely to be set afoot independently of changes in the balance, then the argument does not apply, and there is no certainty about the result. In any case, the creation of such a balance would set up income effects inimical to it, so that the extent of the movement would be unlikely to be large.

A slightly different way of posing the problem is to suppose that both countries have idle resources, and to ask whether depreciation would make it possible to sustain a controlled increase in domestic expenditure (unmatched by any similar increase abroad) without producing an adverse balance. Since depreciation with constant expenditure has been shown to improve the balance, there is presumably some increase in expenditure which could be sustained, consistently with the maintenance of a neutral balance, with an appropriate amount of depreciation. This would not, of course, have any deflationary effect on the foreign country.

To sum up, the first and negative part of this paper tried to show that the theory of flexible exchanges is not a good subject for analysis in terms of elasticities and marginal propensities; the number of variables is too large and the functional relationships too complicated. It has only been handled in this way with tolerable simplicity by constructing models which leave out essential features of the adjustment mechanism, and the attempt to draw policy conclusions from such models is bound to be misleading.

The second part of the paper attempts to make some generalizations based on the pure theory of foreign trade, and which might reasonably be expected to apply to real world conditions. The theory lacks the precision of the elasticity formulae, and I have no doubt that, in subtler hands than mine, it is capable of a great deal of refinement. It is, therefore, advanced only very tentatively. I feel, however, that it does at least tell us when depreciation is, and when it is not, likely to be useful. It will not cure the balance-of-payments problems attendant on domestic inflation; it is not likely to help much in mitigating the effects of a foreign depression; and it will be of very limited usefulness as a purely beggar-my-neighbor remedy. On the other hand, when used in conjunction with a controlled increase in domestic expenditure, depreciation may help in the escape from a position of underemployment equilibrium. The chief usefulness of flexible exchanges is, however, when both the countries concerned are enjoying a high level of domestic employment, but without inflation. It is here that our conclusions differ radically from those of the elasticity approach, for our analysis has shown that—on assumptions which are by no means beyond the powers of a sensible monetary and fiscal policy—depreciation is bound to cure an adverse balance. It would thus appear that we have underestimated the flexibility of the international economic system. The path to free convertibility, multilateral clearing and the removal of quantitative restrictions will certainly not be smooth, but it need not be the impassable jungle which we have sometimes been led to expect.

OBSOLESCENCE AND TECHNOLOGICAL CHANGE IN A MATURING ECONOMY

By MARVIN FRANKEL*

It is a frequently asserted proposition in economic literature that older, industrialized countries such as Britain suffer a disadvantage relative to newer, industrializing countries. More generally, it is argued that both individual industries and entire economies, once they have reached an advanced state of development, experience difficulty in assimilating later and more modern techniques. The time comes, in the words of Veblen, when installations, having been "placed and constructed to meet the exigencies of what is now in a degree an obsolete state of the industrial arts," and having changed little since their origin, "are, all and several, 'irrelevant, incompetent and impertinent' in the same degree in which the technological scheme has shifted from what it was when these appliances were installed."[1] As a result, costs are higher and productivity lower than they ideally ought to be, and plant and equipment are old and inefficient.

A variety of hypotheses has been advanced in further explanation of this state of affairs. They may be grouped conveniently, if roughly, into three categories: those which stress institutional rigidities; those based upon resource inadequacies; and those emphasizing the effects of sunk costs. For shorthand purposes, let us term these categories respectively the institutional, the environmental and the technological.

In the first category belong such common factors as labor resistance to technical change, entrepreneurial provincialism, lack of knowledge, immobilities of labor and money capital, and more generally, archaic modes of thought and patterns of action. These, it has been said, mature and strengthen as an industry or country advances industrially, so inhibiting innovation and modernization adjustments.[2]

In the second category, termed environmental, should be put those

Wilson for statistical assistance

[1] Thorstein Veblen, writing on Britain in *Imperial Germany and the Industrial Revolution* (London, 1915), Ch. IV, "The Case of England," p. 127.

[2] In this category belongs a substantial part of Veblen's explanation, which runs in terms of "custom, wont and usage," for British backwardness. See *ibid.*, Ch. 2-4. Here too should be put what George W Terborgh has called "a failure of *reequipment* policy"

hypotheses which posit as the cause of retardation the presence of limitational elements—limited supplies of land or other resources. So-called modern methods may require that certain factors be used in quantities or ratios that are uneconomic for some industries and areas. Thus a country which, at the inception of its industrialization is plentifully endowed with the resources necessary to modern production methods, may subsequently find that some of those resources have become scarce and expensive. Or it may find that a changing technology requires new resources that are in short supply. In either case it will adapt only haltingly and with difficulty to the new ways.[3]

It is with the third or technological category, which embraces effects attributable to sunk costs, that this paper will deal. The relevant hypothesis can be stated as follows: As an industry (or industrial economy) grows and adapts to changing and increasingly complex production methods, interconnections, more or less rigid, develop among its technological components—among machines, plant, transport network and raw material supplies—that make increasingly difficult the introduction into the system of new, cost-saving changes. It may then happen that the entire system becomes obsolete because, as Veblen has observed, "An adequate remedy by detail innovation is not always practicable; indeed, in the more serious conjunctures of the kind it is virtually impossible, in that new items of equipment are necessarily required to conform to the specifications already governing the old."[4] Unable to utilize the new production methods, the industry continues with its old ones. As a result, its costs are higher and labor productivity lower than they would be in a less "mature" industry. The old industry finds itself penalized for having taken the lead and shown the way to its young competitors in other regions.

This view seems to contradict that implicit in orthodox cost-price theory, according to which the rational entrepreneur or manager will introduce a cost-saving method either immediately or at some later date

---

lack of an adequate technique for analyzing the replaceability of equipment ". . . Britain knew how to build great industries but never learned how to rebuild them" "Capitalism and Innovation," *Am. Econ. Rev.*, Proceedings, May 1950, XL, 122.

[3] Under this heading, in addition to explanations resting directly on absolute or relative resource shortages, fall explanations based on logistic theories of growth and, in part, those involving a frontier thesis. Implicit in the logistic function is the notion of a factor or factors in short supply that exert increasing resistance to growth; while the frontier thesis is premised upon a plentiful land supply, development and settlement of which profoundly condition production methods and other institutions. At times the dividing line between the institutional and environmental categories may be quite vague. The frontier thesis straddles both categories; and shortage of resources, whether human or natural, can result from artificial as well as natural barriers.

[4] Veblen, *op. cit.*, pp. 125-26. Veblen's discussion of British backwardness runs in terms of both the technological and the institutional.

when the old plant and equipment wear out. Under this latter view, and barring the presence of institutional or environmental factors, the old industry is as free as the newcomer to adjust to the changing times.[5]

The paragraphs that follow inquire into the technological explanation of backwardness and attempt, through reference to conventional cost-price theory, to define the conditions governing its validity. The implications of those conditions for a maturing industrial economy are then explored. Finally, some observations are offered on the extent to which the conditions prevail in practice.

I. *Innovation Criteria*

At the outset it is necessary to distinguish between method innovation, a change in the technique for producing a given product, and product innovation, a change in product type or quality. Because abstraction from the complicating effects of product innovation will simplify analysis of our central problem, our discussion relates mainly to method innovation.

The analysis requires use of two cost categories: past or sunk outlays, and future outlays. Past outlays denote expenditures already made which are allocable to some future production period and which must be recovered from future revenues. The undepreciated portion of costs sunk in capital equipment is the principal type of such outlays, and the only type our analysis will explicitly treat.[6]

Future outlays denote all costs that will be incurred over some future production period: costs for labor, raw materials, inventories, repair and maintenance, etc. Also included are outlays for replacement of capital equipment or for new capital equipment which have not yet been made but which must be made over the coming years.

The total costs of any production method are represented by the sum of the past and future unit outlays associated with its use. For an old method already in use, past outlays always are some positive amount unless the cost of equipment has been completely written off For a new method not yet adopted, past or sunk outlays are zero, and total costs are represented by future outlays.

Let us limit consideration to assets of the one-horse-shay variety.

[5] For a statement of this view see F. R J. Jervis, "The Handicap of Britain's Early Start," *The Manchester School*, Jan 1947, XVI, 116, 118.

[6] Some fraction of past outlays for research, training programs and advertising also fall into this classification Strictly speaking, outlays for raw materials and inventories already in hand also are past outlays But here the interval of prepayment is relatively short—usually less than a year—and the sums involved are not sunk in specialized equipment but are more readily recoverable For these reasons it is more convenient to consider raw material and inventory costs as current operating costs and to treat them as if they were future outlays.

Let us further define the production period to which costs and revenues are allocated as the remaining useable life of the capital equipment of the old production method.

Given these definitions and conditions, the criteria governing whether and when to introduce a new production method are, in principle, clear enough. A change should be made only if it will result in an increase in total profit. In making the comparison between old and new methods—and neglecting the effects of taxes—the sunk outlays of the old method have no relevance; only future outlays need be taken into account. This is so because costs which are sunk continue and require payment regardless of whether the new method is adopted.[7] If total profit from the new method—the excess of total revenue over total cost—exceeds total revenue less future costs of the old method, then the old method should immediately be replaced. If, on the other hand, total profit from the new method falls short of revenue less future costs of the old method but exceeds revenue less total costs of the latter, then the old method should be continued in use until the fixed plant is worn out.[8]

These criteria apply whether a firm is young or old, whether it is in a competitive or monopolistic market situation, and whether it is publicly or privately owned.[9] Two further points are worth noting.

[7] If payments, whether to stockholders or bondholders, are defaulted, then for purposes of innovation decisions the case may be treated as if the equipment were fully amortized, *i.e.*, sunk costs are zero. To the extent that the equipment has a positive scrap value, its cost may be treated as an addition to the future outlays of the old method or a deduction from the future (total) outlays of the new method. In the extreme case where the scrap value equals the unamortized balance, that entire balance may be treated in this way.

[8] In comparing the two methods, the optimum period of use for each must be determined. Under the specified assumptions, this period for the old method is the remaining useable life of its fixed capital, while for the new method it is the durability of the new fixed capital The periods of both must then be adjusted to the same time base and all magnitudes reduced to present values It seems desirable also to make the comparison when each method produces at its optimum rate of output. With these points in mind, the propositions in the text are readily demonstrated

Let P = past outlays of the old method
F = future outlays of the old method
$F + P$ = total costs of the old method
T = total costs of the new method
R_1 = total revenue from the old method
R_2 = total revenue from the new method

Adoption of the new method will not eliminate P since these costs are sunk and continue regardless of the method used. Hence only if $(R_2 - T) > (R_1 - F)$—the criterion for immediate replacement—is $[R_2 - (T + P)] > [R_1 - (F + P)]$. If $[R_1 - (F + P)] < (R_2 - T) < (R_1 - F)$, then when the equipment wears out $(R_2 - T) > (R_1 - F)$. This is so because at this point F is augmented by replacement costs.

[9] Our simplified formulation—assumptions and criteria—will suffice to elucidate the problem at hand; it is not designed to explore the many complications which may arise in making replacement—innovation decisions. For a discussion of replacement criteria under more complex and more customary conditions, see George Terborgh, *Dynamic Equipment Policy* (New York, 1949), especially Chapters II, V, VI, and XI.

First, the new firm will utilize the latest, cheapest method when it commences operations and as it expands, and its rate of expansion is apt to be more rapid than that of the old firm. This method, if its profits fall short of the excess of revenue over future costs for the older method, will be one which replacement criteria deny to the old firm until such time as it must replace its equipment. Second, in the absence of factors making for an increase in demand, and other things being equal, a new method will be introduced sooner in a competitive than in a monopolized industry.[10] In the former, entry of new firms and expansion by old ones will result in an immediate introduction of the new method no matter how slight the cost-saving, and prices will tend to fall to the extent that cost-savings permit. In the latter, unless profits from the new method exceed the excess of revenue over future costs for the old method, there will be little tendency to change until the old equipment is worn out.[11]

In this orthodox cost-price approach to the problem and, to repeat, abstracting from institutional and environmental factors, it appears that both old and new firms will employ the latest and cheapest method available at the time of investment commitments. This may mean that a more modern method with lower total costs will be used by the new firm. The differences in method and in cost, regarded by some as an indication of retardation or backwardness on the part of the old firm, may persist for a period measured by the remaining usable life of the old equipment.[12] But then replacement will take place. If, by this time, further technical advances have occurred, the old firm should be even more modern than its rival.

During the interim when cost and equipment differences exist, the old firm, if it has not correctly estimated its obsolescence rate, will face a financial burden in the form of some fraction of the unamortized balance on its equipment. Investors will suffer accordingly, for such is the penalty for faulty (normal?) foresight. But the burden will have no counterpart in terms of current real resource costs. *Individual* investors may calculate that they would have been better off never to have

[10] Other things may not always be equal. Schumpeter has stressed conditions frequently present in monopoly and absent in competition which conduce to rapid technological progress. See his *Capitalism, Socialism and Democracy* (New York, 1947), Chs. VII and VIII.

[11] For an analysis of innovation under various market structures, see William Fellner, "The Influence of Market Structure on Technological Progress," *Quart. Jour. Econ.*, Nov., 1951, LXV, 556-77.

[12] Our discussion of innovation criteria was introduced with the one-horse-shay assumption. It is, of course, conceivable that through appropriate maintenance expenditures equipment can be kept in use indefinitely. However, in practice one of two things is likely to happen: (1) Variable costs will rise as the equipment ages and replacement with the new method will become profitable; or (2) continued technological advances will eventually make introduction of the new method profitable.

taken the initial gamble. But the *community* cannot for that reason regret the addition to its capital stock and the income generated by it. Unlike the private investor, it would not necessarily be better off if the investment had been postponed. On the contrary, the community might justifiably consider itself fortunate to possess, in its old equipment, an economizing production alternative not open to its young competitor.

II. *Application of Criteria to an Interrelated Technology*

Where, if at all, in the foregoing scheme of things can a counterpart be found for Veblen's retardation thesis? Or if, in order to find support for his views, one must depart from that scheme, then with which of its assumptions must one dispense?

Veblen's conception of technology is an organic one which views the structural and functional aspects of the production process as closely interrelated. As a firm, industry or country develops and its technology becomes more intricate, interconnections proliferate which limit sharply the range of new methods it can assimilate. Not all new techniques can be utilized, but only those which can, in some sense, conform to the past. Unlike the young enterprise or newly industrializing country which is, technologically, a *tabula rasa* without any system whose contours demand conformity, modernization for the established enterprise or country is limited by the extent to which the necessary changes can be made to "fit" the existing system.

This view of things contrasts with the traditional one of the technological unit as divisible, the capital components of the production process, such as tools, machines and plants being regarded as self-contained and individually replaceable, with each item subject to separate costing and amortization. Here the technological unit relevant for a replacement or innovation decision is relatively small, whereas in the other case it is relatively large.

Where the technological unit is large, as Veblen implies it generally is, modernization may not take place as readily as when it is small. Let us visualize a simplified production process consisting, on the technical side, of a plant which includes a series of different machines each designed to perform a necessary operation. In addition certain quantities of labor and raw materials are required. Let the plant comprise past outlays and the labor and raw materials future outlays.

If now a new machine is developed, then on conventional suppositions about technology and depending upon the degree of profitability of the new machine, two alternatives are possible: Either the old machine will be replaced immediately with the new one or it will be continued in use until it no longer is serviceable. Where technological interconnections exist, however, it may prove impossible to fit the new machine into

the prevailing pattern of operations. It might be too large for the available plant space, or too heavy for present flooring, or impossible to adapt for the continuous feeding mechanism that served the other machines, or unsuited to processing the semifabricated product in the precise way required for subsequent operations. It might be the case, that is to say, that the new machine could not be introduced unless the entire production sequence or a large fraction of it were replaced.

Confronted with this situation, the enterprise would compare the new and old methods not on a component or machine basis but on an entire plant basis since only by replacing existing plant in toto could it utilize the new machine. Even if, on the machine basis, profits from the new method exceeded revenue less future cost of the old method, comparison on an entire plant basis probably would find profits from the new method below revenue less future costs of the old method; rarely would the gains resulting from improvements in a single machine suffice to warrant immediate replacement of the entire plant.[13]

The situation is one which calls for a delay in replacement until the existing plant wears out. Unfortunately, however, it is highly probable that the durability of each of the several machines will differ. To replace a worn-out component of the old plant with one that fits the specifications of the new would require the discard of other components of the old plant which still were quite serviceable. On the other hand, to replace the worn-out component with a duplicate of itself would entail continued use of the older method; unless several or all of the components wore out simultaneously at a later date, the cycle would repeat itself. In these circumstances, modernization would be indefinitely postponed.

At this juncture two questions arise. First, what are the implications for unit costs of an interrelated technology? If an old production method is continued in use when, in absence of interrelatedness, it would have been replaced, then costs will tend to be higher than they otherwise would be. How much higher will they tend to be? Second—really a prior question—what are the conditions, aside from the fact of interrelatedness, which determine how much higher unit costs will be?

Mathematical formalization of our problem, as developed in Part I of the appendix, points to six determining variables. They are:

- t, the number of components in the old method that are linked together, or the degree of interrelatedness;
- r, the discount rate;
- nt, the durability of capital (assumed the same for both methods);
- k, the ratio of total variable to total fixed costs of the old method;

[13] Except as noted in a few places, it is of no particular consequence to the discussion whether innovation affects but a single component or affects several or all of them.

h, the ratio of the fixed costs of the new to the fixed costs of the old method;

$-1/\alpha = E$, the elasticity of demand (always negative but treated in the text without regard to sign).

For any set of values assigned these variables, it is possible to determine by how much average total unit costs of the new method can fall short of average total unit costs of the old method and still leave the enterprise content with the old method. Table I shows the outcome in a number of specific instances. To illustrate with row 4, if there are 2 components, the discount rate is 5 per cent, the durability of capital 30 years, the ratio of total variable to total fixed costs 4 to 1, new capital costs are equal to old capital costs, and the elasticity of demand is 6, then the enterprise will continue with the old method as long as total unit costs of the new method do not fall below 80.1 per cent of those of the old method.

In rows 2 through 7 of the table and again in rows 9 through 14 the values assigned each of the variables are changed once. By compar-

TABLE I.—MINIMUM UNIT COST RATIO COMPATIBLE WITH USE OF OLD METHOD[a]

	Number of Components	Discount Rate	Durability of Capital (years)	Ratio of Variable to Fixed Costs, Old Method (ratio to 1)	Ratio of New to Old Fixed Costs[b] (ratio to 1)	Elasticity of Demand	Minimum Unit Cost Ratio[c] (per cent)
Row	t	r	nt	k	h_1	E	
1	2	.05	15	4	1	6	90.3
2	4	.05	15	4	1	6	87.0
3	2	.10	15	4	1	6	81.1
4	2	.05	30	4	1	6	80.1
5	2	.05	15	1	1	6	60.9
6	2	.05	15	4	1.50	6	84.0
7	2	.05	15	4	1	2	93.8
8	4	.10	30	1	1.50	2	18.6
9	2	.10	30	1	1.50	2	20.8
10	4	.05	30	1	1.50	2	37.9
11	4	.10	15	1	1.50	2	39.4
12	4	.10	30	4	1.50	2	60.8
13	4	.10	30	1	1	2	21.4
14	4	.10	30	1	1.50	6	20.9

[a] Based upon constant variable cost functions for both methods.

[b] h_1 gives the ratio of the fixed costs of the new component, responsible for the cost-savings, to the fixed costs of the old component it displaces.

[c] The figures in this column express, for the conditions specified and at respective optimum outputs, the ratio of average total unit costs of the new method to average total unit costs of the old method at which the enterprise would be indifferent between the two methods.

ing the former set of rows with row 1 and the latter set with row 8, it is possible to observe the influence of each variable on the unit cost ratio. We find that increases in t, r, nt and h lower the ratio and that increases in k raise it. The effects of E are more complex. Increases in E may increase or reduce the ratio, depending upon the values jointly assumed by the other variables.

III. *Some Implications of Interrelatedness*

A hypothetical example should help to illustrate the influence of the several variables and should provide a basis for better appreciating the significance of interrelatedness.

Take the case of a given industry in each of two regions, A and B. In region A the industry is old and relatively "mature," has largely saturated its market and is experiencing a comparatively slow rate of growth. In region B the same industry is in an embryonic state, has barely tapped its market potential and, as is the case with most industries in their early stages, is undergoing rapid expansion. Assume further that in both regions the industries employ the same production method—one entailing use of a fixed factor comprising several interrelated components—and enjoy the same costs and productivities.

If now there should be a cost-saving innovation which affects a single component and if, for reasons like those specified earlier, the fitting of this innovation into the prevailing set of components is impossible, so that use can be made of it only if a completely new set of related components are simultaneously adopted, then the two industries will be affected differently. The industry in region B (industry B), because it is extending its facilities, will construct those facilities to the specifications required by the innovation. It will largely bypass the complications of interrelatedness by utilizing the innovation, together with the modified auxiliary components, as additions to existing capacity.[14] The industry in region A (industry A), because it has need to extend its capacity little if at all, will adopt the innovation and its related components only if it can use them profitably as a replacement for its existing facilities.[15] Whether it can or not will depend upon the values of the several relevant variables. The table indicates that an innovation which

[14] It will not *completely* by-pass the complications since, unless it is starting from scratch, it will possess some facilities based on the old method But the fewer those facilities and the more rapid its rate of growth, the smaller will be its problem. Moreover, for reasons explained later, it probably will be true that complications facing the new industry in respect solely of its old equipment will be fewer than those facing the old industry, particularly if the new industry is part of a newly developing industrial environment and the old industry a part of an established and mature industrial environment.

[15] This statement assumes that, for whatever reason, entry of new firms is blocked As is developed in Section V, interrelatedness may itself constitute a barrier to entry.

offers substantial savings may be compatible with continued use of the old method.[16]

Assuming for the sake of simplicity that row 4 describes the present situation and that the minimum unit cost ratio is the actual ratio, the following observations are applicable:

1. Revenue less future costs for industry A is equal to revenue less total costs for industry B. The present value of future costs is identical for both industries.

2. Industry B's unit costs are lower than those of industry A by 19.9 per cent. If the innovation is labor-saving, industry B's labor productivity will be higher than A's.

3. A logical procedure for industry A would be to write off the whole of the remainder of its past investment. Let the aggregate of fixed costs—the total of outlays for the several components—of the old method equal C and assume that the components wear out at intervals equally spaced in time. Then if the timing of the innovation coincided with the wearing out of the component it would replace, the necessary write-off would amount to $\frac{1}{4}C$.[17]

4. It seems likely that in the ordinary institutional setting the industry frequently would be unwilling or unable to write off the necessary amount—in the present case a sum equal to 25 per cent of its original investment. More probably it would maintain its capital at full book value, or would endeavor to do so. Whether it succeeded would depend upon whether it faced competition from industry B in its own market, industry B's market or in third markets. Without such competition it could continue as though the innovation had never been developed, though with higher costs, lower productivity and higher prices than industry B.

5. If a capital write-down is not undertaken, if an inflated capital base is perpetuated and if, in absence of competition with industry B, prices are maintained, investors will, in effect, have shifted responsibility for their lack of perfect foresight to other factors whose returns will be lower than otherwise, and to consumers. More generally the level of output of industry A, the distribution of income and the magnitude of savings and investment will be "distorted."

[16] A somewhat similar situation may arise in the absence of interrelatedness, *i.e.*, where $t = 1$. An instance is where the new method yields its savings only at substantially higher levels of output; levels which, with the existing demand function, are unprofitable. However, this does not alter the implications of interrelatedness. In this case its effect is to intensify (rather than originate) the disparity in unit costs between the two methods that is compatible with continued use of the old method. The "net" effect of interrelatedness then becomes the difference between the unit cost ratio when $t = 1$ and that ratio when $t > 1$. This point requires no important qualifications to the observations made in the text.

[17] $\frac{1}{4}C$ because there are but two components one of which has been completely depreciated and the other of which has been depreciated by half.

6. If there is competition between industry A and industry B, prices will tend to fall to the level set by costs in industry B. This may result in a forced write-down of capital in industry A and a reduced return to its investors, or a lower return to other factors, or both. Industry A may then appear as a weak and struggling competitor in interregional trade, with its costs relatively high and its productivity low.

7. The crux of the difficulty to which interrelatedness gives rise is capital obsolescence. From this follow the several secondary effects mentioned above. To be sure, this difficulty arises as well in a conventional technological world where t equals 1. But the magnitude of such obsolescence generally will be considerably less than in a world ruled by an interrelated technology. In the illustration just used (row 4 of Table I), had t been taken as 1 instead of 2 there would have been no obsolescence problem since timing of the innovation was assumed to coincide with the wearing out of the relevant component. More generally we can say that when $t > 1$ and cost and demand conditions relating to the old and new methods are such as to leave the decision-maker indifferent between them then, depending on the timing of the innovation, the amount of obsolescence will vary from a minimum of $C\frac{t-1}{2t}$ to a maximum of $C\frac{t+1}{2t}$. When $t = 1$, obsolescence will vary between zero and an amount equal to the total fixed cost of the single component.[18] Should the timing of the innovation coincide with the wearing out of the relevant component, the *increase* in obsolescence resulting from an interrelated technology will be given by the expression $C\frac{t-1}{2t}$. As t increases, this expression approaches a limit of $\frac{1}{2}C$.

IV. *Effects on the Rate of Innovation*

To answer the question, "How do changes in each of the variables affect the degree to which, with interrelatedness, innovation is retarded," it is necessary to consider the effect of such changes on (1) the "profit gap"; and (2) the "profit potential" of the new method.

Interrelatedness has the effect of requiring the new method, if it is to be introduced, to earn higher profits than would otherwise be necessary. Let the difference between required profits with interrelatedness and required profits without it be called the "profit gap." The size

[18] It must be remembered that for $t = 1$ this fixed cost is smaller than for $t > 1$. Thus, maximum obsolescence in the former case may well be less than even the minimum obsolescence in the latter case

of this gap may be taken, in any particular case, as a measure of the handicap imposed on innovation by interrelatedness.

The "profit potential" is simply the profit function of the new method, since this function describes the ability of the method to earn profits. Besides affecting the profit gap, changes in certain of the variables will, other things equal, alter the profit potential. A change in one of the variables might, for example, increase the profit gap but increase the profit potential also. In this case we could not determine, without further information, whether the change served to intensify or diminish the delay interrelatedness causes to innovation.

It is tempting to infer that the combined effect on the profit gap and the profit potential[19] of a change in any one of our six variables is similar to its effect on the minimum unit cost ratio. Thus, if an increase in a variable reduces the ratio, it might be supposed that it also would increase the delay in innovation by increasing the profit gap and reducing the profit potential. However, that is not strictly true. It is found that increases in r and reductions in k increase the profit gap and reduce the profit potential; that increases in t increase the profit gap without affecting the profit potential; that increases in h reduce the profit potential without affecting the profit gap; that increases in nt increase the profit gap but leave the profit potential indeterminate; and that increases in E generally decrease the profit gap but have an indeterminate effect on the profit potential. In the last two instances the outcome on balance is indeterminate unless the conditions of the problem are further specified. With respect to changes in the other four variables, a few words will be offered on the implications for a developing economy.

The illustration used earlier assumed that industry B, by virtue of its later start than industry A, grew more rapidly than the latter. This more rapid growth meant that a t factor of any given size would retard innovation less for B than for A. The earlier model also assumed that the two industries employed the same techniques and had the same costs. However, it is generally the case that in less industrialized regions, in contrast to more advanced regions, factor price ratios conduce to employment of simpler, direct-labor production methods. If industry B is in such a region, while industry A is in an advanced one, then industry B can be expected to use relatively little capital and capital of a relatively simple type. In this event we have another reason why the t factor—lower now for B than for A—will be less unfavorable to B.

This argument implies that B's state of technology is more rudimentary than A's and does not, therefore, reinforce the case for lower

[19] See the Appendix, Part II, for the relevant functions.

costs and greater competitive strength in B than in A.[20] But since a lower t means a smaller handicap to innovation, it does suggest that B will be able to move up the technological ladder from its existing, rudimentary position more rapidly than will A from its existing, more advanced position. It suggests, in other words, a supplementary reason for supposing that a young industry will grow faster than an older, more fully developed industry. It also helps to explain why industries in newly developing economies tend to catch up with their counterparts in more advanced economies.

Since region B is underdeveloped as compared with A, factor price ratios will conduce to the use of a less roundabout method by industry B than industry A. For this reason we should expect the ratio of variable to fixed costs, k, to be greater for industry B. With other things equal, larger k values cause a smaller handicap to innovation than do smaller k values. Industry B will, on this account, suffer a smaller handicap than mature industry A.

On the other hand, we might expect that r would be higher for industry B than for industry A because of the more limited supplies of capital available to industry B, because of a higher marginal productivity of capital in region B—hence higher opportunity costs for using capital, and because of greater uncertainty in region B as to future investment opportunities and future rates of return. This circumstance would tend to diminish the effects of any given difference in t between industries A and B.

If a generalization is possible with respect to h, perhaps it is that the effects on industries A and B will not differ significantly. Adoption of a new method usually calls for greater capital costs than did the old method,[21] and this probably is as true for the industry in the less developed as that in the more developed region. We may conclude provisionally that h is neutral in its impact, neither intensifying nor mitigating the effects of a difference in t between industries A and B.

The matter can be put in a different perspective by dropping the comparison between regions and industries and applying the same principles to a single industry in a single region as the industry develops and at the same time the region becomes increasingly industralized. As

[20] It is certainly conceivable that B, utilizing much more rudimentary production methods than A, would find it profitable to "jump" to a much higher technological level by adopting a highly capitalistic innovation which A, because of interrelatedness, found it uneconomic to adopt. B would be aided in such a jump by a low t factor and would be hindered by adverse factor price ratios. But in general we would expect both industries to adjust to those new methods which are proximate technologically to the methods they currently employ.

[21] Our reference is to total capital costs, not capital per unit of output. Advancing techniques have brought with them larger optimum outputs. A rising h is therefore compatible with either rising or falling capital costs per unit of output.

the industry and the region develop, a rising t factor will pose a growing handicap to innovation. This handicap will be intensified by a rising ratio of fixed to running costs and mitigated by a falling discount rate. It will be little affected by h, which remains relatively stable. The outcome on balance cannot be determined without reference to empirical data.

V. *The Theory Related to Actual Conditions*

To what extent is our analysis relevant to the complex production conditions prevailing in practice? No precise answer is possible. However, conditions in certain British industries suggest that interrelatedness has been and is a factor of consequence. Supplemental considerations bearing on the relationship between technological and certain institutional factors lend force to this conclusion. Let us take up the supplemental considerations first.

The existence of interrelatedness need not presuppose a rigid and rudimentary interdependence among a series of machines, and it ought not to be regarded as a by-product only of peculiar types of fixed capital. Its compass may include any of the elements, including the institutional ones, that make up an industry's technology. Broadly construed, technology embraces far more than physical plant and equipment. It extends also to the kinds and qualities of raw material, the labor skills, the managerial know-how and the administrative organization necessary to productive activity. Proliferation of interconnections among these elements and between them and plant and equipment is as likely, perhaps more so, as growth of interconnections among elements of plant and equipment alone. A new and more efficient machine may function efficiently, if at all, only if fed raw materials different in kind or quality from those previously used. Or it may require that those materials first be subjected to preparatory processing not previously required. Again, effective use of new equipment may call for direct labor, supervisory or maintenance skills that are not readily available and development of which in adequate quantities would require much time and expense. Or it might happen that certain equipment changes are feasible only if accompanied by a switch from singleshift to multishift working, while a short labor supply makes such a switch impossible. In still other instances use of a new method might require an expansion in output or some change in product quality which firms, for reasons of cost or want of enterprise, are reluctant to attempt.

These few examples point to the very wide field over which interconnections can develop. Elements of an institutional nature in addition to those relating to physical plant and equipment may be involved, blending with and re-enforcing one another. Their effects may not be so

readily measurable as they are where a series of machines are linked together in simple interdependence, but that does not diminish their significance for innovation decisions.

A second consideration relates to the pattern of ownership. If ownership at each of the several stages of production or within each of the stages of production is fragmented, it may prove impossible fully to consider, let alone to adopt a new method. This situation may be described as one where the relevant technological unit is larger than the ownership or decision-making unit. Instances of it can be found in the British textile and steel industries, among others.[22]

Returning for illustration to the example used earlier, suppose that each of the interrelated components is separately owned. If then a cost-saving substitute for one of the components is developed, the user of the component in question will be unable to innovate barring cooperation from other users. In this situation at least three alternatives present themselves: (a) The user of the obsolete component could try to induce cooperation from others by offering to share his gains with them. He might do this by quoting higher prices to his suppliers and lower prices to his purchasers. However, the potential gains from the innovation would have to be large indeed to provide, after being shared three ways, the necessary incentives to change. Further, the risks would devolve mainly upon a single user, the initiating innovator, creating a formidable obstacle to action. (b) The user of the obsolete component could go into competition with those whom he formerly supplied or from whom he formerly purchased by undertaking the several related phases of production himself; alternatively, he might buy out his suppliers and/or purchasers. He then would be in a position to adopt the new method. For several reasons—lack of knowledge of the related phases of operations and their costs, lack of financing,[23] reluctance to make heavy outlays in face of uncertainty, pre-emption and monopolization of the related fields by others—he might well be unable or unwilling to pursue either of these alternatives. (c) Not least likely is the possibility that the new method would be given little or no consideration. Since its introduction would require solution of problems external to the firm, the firm might justifiably disregard it, just as it disregards all those events to which it has no power to adjust.[24] In situations of this type

[22] *Infra*, pp. 312-13

[23] Lack of financing is important Even if the entrepreneur is convinced on the basis of proper calculations that an innovation is economically sound, he may not be able to convince the banks or the capital markets of this; they must discount because of their uncertainty that the entrepreneur is right.

[24] The situation would not differ basically if innovation gains were distributed all along the line instead of being limited to a single component. Successful adjustment would remain outside the power of any single firm. Cooperation among firms and a measure of coordination among them in effecting changes still would be necessary.

there is no definite limit to the cost disparity between old and new methods compatible with continued use of the old method.[25]

The last few paragraphs lead to the conclusions that virtually all of the elements in the production process are susceptible to the effects of interrelatedness and that interrelatedness need not exist in any rigid, formal, measurable way to be a factor of consequence for innovation decisions. They also indicate that interrelatedness may be important for an industry even where firms fail, because of problems generated that are external to themselves, to give it explicit recognition.

The British railway system presents something of a classic case in illustration of our general thesis. As a result of a decision as to loading gauge made in the nineteenth century, tunnels and stations restrict vehicles to eight feet in width, while on the continent and in the United States the figure is between nine and ten feet with a correspondingly greater latitude in height. This condition affects not only the possible size of car and load. As early as 1900 it prevented use in Britain of the most powerful locomotives essential to maximum economy.[26] Veblen had reference to this situation when he spoke of "the silly little bobtailed carriages used in British goods traffic; which were well enough in their time, before American or German railway traffic was good for anything much, but which have at best a playful air when brought up against the requirements of today. Yet the remedy is not a simple question of good sense. The terminal facilities, tracks, shunting facilities, and all the ways and means of handling freight on this oldest and most complete of railway systems, are all adapted to the bobtailed car. So, again, the roadbed and metal, as well as the engines, are well and substantially constructed to take care of such traffic as required to be taken care of when they first went into operation, and it is not easy to make a piecemeal adjustment to later requirements."[27]

[25] Attainment of economies through integration of facilities and their operation on a coordinated basis is generally recognized as a major stimulus to large-scale industry and as a factor of particular importance during the formative period of industrialization. Our concern here is with instances where integration ought to have been undertaken and was not, rather than with instances where it was successfully achieved whether it ought to have been or not.

[26] Charles H. Grinling, "British Railways as Business Enterprises," in *British Industries*, edited by W. J. Ashley (London, 1907), p. 156.

[27] Veblen, *op. cit.*, p. 126. He went on to draw the not necessarily valid conclusion that, in the community's interest, the out-of-date equipment and organization probably ought to be "junked." He doubted that they would be because "it is the discretion of the business men that necessarily decides these questions, and the whole proposition has a different value as seen in the light of the competitive pecuniary interests of the business men in control." Our analysis has shown that it may be economic—in the social as well as private sense—to continue with an old, seemingly expensive method even though a new, cheaper one be available. In the case of railroads, where the t factor is large, the durability of capital great and the ratio of running to capital costs low, the cost disparity consistent with perpetuation of an old system doubtless is very large. If interrelatedness is internal and not external to the

Reference to developments in the British iron and steel industry during the latter part of the last century also will illustrate our thesis. In the 'sixties, 'seventies and 'eighties a number of technical changes were evolved which offered prospect of substantial economies in various phases of production. New and commercially feasible methods of steel ingot production were opened up through introduction of the Bessemer converter and the open hearth and electric furnaces; advent of the rolling mill made possible phenomenal savings in the shaping and finishing of steel products; the optimum size of the blast furnace was greatly increased; and significant fuel economies all along the line became possible. Most important, no single one of these changes would yield its potential savings in full except in conjunction with the others, and this fact made necessary a juxtaposed grouping of the several elements of the production process.

The economies attainable from such a grouping derived from several sources: from a reduction in transport and handling charges; from a fuller and more balanced utilization of plant capacity; from easier and more accurate control over product quality; and from fuel economies.[28] While there could be no absolute rule, concentration of coking ovens, blast furnaces and rolling mills on one site was generally found to be the most suitable arrangement. But it was more than merely placing the various kinds of plant in the same location. They had to be concentrated "in such proportions and on such a scale that the whole plant could work effectively and economically. . . . There had to be a sufficient number of coking ovens, blast furnaces and steel furnaces both to keep one another employed and to meet the requirements of the rolling mills."[29]

The technical changes that made possible the economies in question materialized in an era when the British iron industry already was well developed and resting solidly on the foundations of an older technology, when its rate of growth had declined to a relatively low level, and when its ownership structure had crystallized in a pattern inconsistent with the new technological need for integrated operation. As a result, in part at least, those changes had hardly begun to be assimilated by the third

---

firm, and if pecuniary interests control decisions, what is apt to occur is not a failure to modernize when modernization ought to be undertaken, but rather a failure by businessmen to write down their capital (or refusal by a utility commission to allow them to do so even if they would). In the case of monopolistically controlled railways, whose rates are regulated on a cost basis, this would result in an inflated capital base, "excess" returns to owners, and unduly high charges to consumers.

[29] *Loc. cit.*

decade of the twentieth century.[30] Things appeared to be little better by midcentury.[31]

As a final illustration, we might compare the adjustment to the perfection of the automatic loom of the British with the American cotton weaving industry. The loom was first introduced around the turn of the century and by 1914 represented 31 per cent of the looms in operation in the United States. By 1919, the figure was 51 per cent and by 1939, 95 per cent. In Britain, by 1939, but 5 per cent of the looms were automatic and the figure is hardly greater today.[32] Of the few principal circumstances contributing to this outcome, it may be urged that technical interrelatedness is one. Lancashire's industry experienced its great growth during the nineteenth century. It grew little after 1900, reaching its apogee with the first world war. In contrast, textile weaving in the United States expanded rapidly after 1900, and this expansion was coupled with a locational shift from the New England States southward that augmented the opportunity for technical modernization.

Because it grew but little, Lancashire's modernization problem was and remains primarily a replacement problem. Yet introduction of automatic looms demands more than replacement of one machine by another. For a great many firms it requires redesign of the weaving shed—often its complete rebuilding, strengthening of flooring, elimination of pillars, and respacing of machinery. It calls for equipment and method changes in the preliminary processing of yarn;[33] in this regard it gives cause for an integration of spinning with weaving, something for which the industry, long established on horizontal lines, is not well suited. It creates a need for product simplification and for a change in the traditional practices of converters in allocating orders to weavers, so that long runs of given fabric types may be attained.[34] Certain of the inter-

[30] In 1928 the Balfour Committee observed ". . . that few British works, if any, are modern throughout in equipment and practice, with coking ovens, blast furnaces, steel furnaces and rolling mills adjacent to one another, and making full use of waste gases. Moreover, there is not infrequently a lack of balance between the productive capacity at different stages, e.g., deficient coking oven or blast furnace capicity." *Ibid*., p. 27.

[31] See R. A. Brady, *Crisis in Britain* (Berkeley, 1950), pp. 203-13. These pages provide an excellent illustration of the thesis under discussion.

[32] R. Gibson, *Cotton Textile Wages in The United States and Great Britain, 1860-1945* (New York, 1948), p. 70.

[33] For example, it requires weft yarn in larger packages. Modern ring spinning equipment will produce yarn in these larger packages or in a state suitable for easy rewinding, but most of the existing spinning equipment in Lancashire will not.

[34] For data on use of the automatic loom in Lancashire and some of the problems to which its introduction gives rise see the Cotton Board Conference reports, *Equipment and Labor Utilization in the Cotton Industry*, 1947; *Production, Quality, Costs*, 1948; *Reequipment and Labor Deployment*, 1948. See also *Cotton Weaving*, a report of the Anglo-American Council on Productivity (London, 1950).

connections, it will be noted, are external to the firm. Their presence, together with those internal to the firm, constitute a part of the explanation for Lancashire's continued reliance on the old power loom.

VI. *Conclusion*

By way of concluding, let us ask two questions: Is it the case, as Veblen alleged,[35] that Britain is paying a real penalty for having taken the lead and for having shown the way to countries industrializing at a later date? If she is paying a penalty, does it follow that the United States, Germany and Japan will be paying a comparable penalty at a later date?

To the first question there is a twofold answer. First, in face of a dynamic technology, interrelatedness always gives rise to an unusually heavy obsolescence problem—a problem which at best need have no deleterious effects but which, under usual conditions, can have distorting influences upon costs, prices, competitive strength, income distribution and future rates of growth. Second, where interrelatedness is external to the firm—where the technological unit is larger than the decision-making unit, as it frequently appears to be, the firm (or industry or economy) will face an additional handicap in its inability to adopt a new method when, by economic criteria, it ought to do so. These consequences, which would not arise in absence of interrelatedness, represent a real penalty on Britain for her early industrial leadership.[36]

As to the second question, let us note only two things: First, the effects of interrelatedness depend upon a number of variables some of which have been formalized mathematically and others of which, like the rate of growth and pattern of ownership, have been treated qualitatively. The relative importance of the several variables and their interactions determine the significance of interrelatedness, and we can expect both that importance and the mode of their interaction to vary among countries. Suggestions have been made, however, as to the probable tendencies of certain of these variables as the industry or economy matures. Second, it is well to remember that technological interrelatedness, with its effects on adaptation to innovation, is but one of many factors that condition the responsiveness of a maturing economy to

[35] The British have not "sinned against the canons of technology. It is only that they are paying the penalty for having been thrown into the lead and so having shown the way" *Op. cit.*, p 128.

[36] This is not at all to say the British would have been better off could they have postponed their march to industrialization. Neither is it to say *categorically* that they would be better off if they did not have to reckon with interrelatedness. After all, prodigals might live longer and more happily if they were not able to live so lavishly But surely it is reasonable to prefer the faster innovation, lower costs and higher returns which interrelatedness prevents to the slower innovation, higher costs and lower returns which it causes.

technological change. The other factors may seriously affect the role of interrelatedness one way or the other.

Mathematical Appendix

I

Insight into the effects of interrelatedness on unit cost and into the conditions determining the magnitude of those effects is obtainable through formalization of the problem as follows:

Let t = the number of components in the old method.

nt = the durability of capital of both the old and new methods.

n = the interval of differential durability, *i.e.*, the interval between replacements of the components of the old method. By assumption, $n=(nt)/t$. That is, the interval between replacements of each of the components is assumed to be the same. Allowing n to be uniquely dependent upon t and nt permits the problem to be set up with one less variable than otherwise.

r = the discount rate.

C = the total capital or fixed cost of the old method over the future period nt.

$c_1=c_2=c_3=c_t$ = the cost of each of the several components that comprise the fixed cost of the old method.

$$\sum_{1}^{t} c_i = tc = C.$$

C^* = the total capital or fixed cost of the new method over the future period nt.

v = unit variable costs of the old method (assumed invariant with output).

v^* = unit variable costs of the new method (assumed invariant with output).

$q_1=q_2=q_3=q_{nt}$ = the annual output with the old method.

$q_1^*=q_2^*=q_3^*=q_{nt}^*$ = the annual output with the new method.

If the comparison is made at a time when one of the components has worn out and requires replacement (and assuming that the salvage value of existing plant and equipment is zero), then the present value of the total of future outlays associated with continued use of the old method becomes

$$c_1 + \frac{c_2}{(1+r)^n} + \frac{c_3}{(1+r)^{2n}} \cdots \frac{c_t}{(1+r)^{n(t-1)}} + vq_1$$
$$+ \frac{vq_2}{(1+r)} + \frac{vq_3}{(1+r)^2} \cdots \frac{vq_{nt}}{(1+r)^{nt-1}}$$

which upon summing and combining terms reduces to

$$C\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}\right]+vq\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]. \tag{1}$$

The present value of the total of future outlays associated with adoption of the new method for the period nt is

$$C^*+v^*q_1^*+\frac{v^*q_2^*}{(1+r)}+\frac{v^*q_3^*}{(1+r)^2}\cdots\frac{v^*q_{nt}^*}{(1+r)^{nt-1}}$$

which upon summing and combining terms reduces to

$$C^*+v^*q^*\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]. \tag{2}$$

Given a demand function of constant elasticity

$$p=\frac{a}{q^{\alpha}} \tag{3}$$

where p=price, q=output, a is some constant and $-\alpha$ is the reciprocal of the elasticity of demand, the respective revenue functions over the period nt become

$$aq^{1-\alpha}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right] \tag{4}$$ and $$aq^{*1-\alpha}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right] \tag{4a}$$

and the profit functions, π and π^*, are

$$\pi=aq^{1-\alpha}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-vq\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-C\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}\right] \tag{5}$$

$$\pi^*=aq^{*1-\alpha}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-v^*q^*\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-C^* \tag{5a}$$

At optimum outputs

$$\frac{\partial\pi}{\partial q}=0,\quad\text{and}\quad q=\frac{v^{-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}} \tag{6}$$

$$\frac{\partial\pi^*}{\partial q^*}=0,\quad\text{and}\quad q^*=\frac{v^{*-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}. \tag{6a}$$

If now at respective optimum outputs the enterprise is indifferent between continuing with the old method and adopting the new method, we have $\pi=\pi^*$ or, with substitutions

$$\frac{v^{1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]\left[\frac{\alpha}{1-\alpha}\right]-C\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}\right] \tag{7}$$
$$=\frac{v^{*1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]\left[\frac{\alpha}{1-\alpha}\right]-C^*.$$

A meaningful economic relationship is that between capital cost outlays and variable cost outlays over the period nt. For the old method

$$\text{Capital cost outlays} = C$$

$$\text{Variable cost outlays} = v\left[\frac{v^{-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\right]nt$$
$$= nt\left[\frac{v^{1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\right]$$

Let

$$nt\left[\frac{v^{1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\right] = kC. \tag{8}$$

Let

$$C^* = hC. \tag{9}$$

With the substitutions permitted by (8) and (9), (7) can be written as

$$\frac{v^{*1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right] \tag{10}$$
$$= C\left(\frac{k}{nt}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}-h\right]\left[\frac{1-\alpha}{\alpha}\right]\right).$$

By postulating indifference between the two methods, *i.e.*, revenue less future costs of the old method equal to revenue less future (and total) costs of the new method, we are in a position to determine the maximum possible effects of interrelatedness on costs. Were the cost-savings available from the new method any greater, its profits would be greater, and it would be preferred over the old method.

When the enterprise is indifferent between the new and the old methods,

what is the ratio, in present values and at respective optimum outputs, between their average total unit costs? For the new method, average total unit cost is given by

$$(11)\qquad \frac{C^* + \dfrac{v^{*1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]}{nt\left[\dfrac{v^{*-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\right]}$$

where the first term in the numerator expresses capital cost and the second term expresses total variable cost, both for the period nt, at the optimum rate of output, and in present values. The denominator gives total output for the period nt when output is at the optimum rate.

With the old method there is a cost allocation problem. Part of the outlays for components purchased in earlier years is attributable to the period nt because those components yield up services and wear out during this period. Similarly, part of the outlays for components to be purchased during the period nt are allocable to the subsequent period. Because of the assumptions of equal durabilities for all components and equal intervals of differential durability, that fraction of earlier outlays allocable to nt is exactly offset by the fraction of outlays during nt that is allocable to the subsequent period. We may simplify further by assuming that the accruals and discounts on these two sums exactly offset each other. Then average total unit cost for the old method is

$$(12)\qquad \frac{C + \dfrac{v^{1-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]}{nt\left[\dfrac{v^{-1/\alpha}}{[a(1-\alpha)]^{-1/\alpha}}\right]}.$$

Dividing (11) by (12), substituting on the basis of (8), (9) and (10), and combining terms gives

$$(13)\qquad \frac{\left(\dfrac{k}{nt}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]\right)^{-1/(\alpha-1)}\left(h+\dfrac{k}{nt}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-\left[\dfrac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}-h\right]\left[\dfrac{1-\alpha}{\alpha}\right]\right)}{\left(1+\dfrac{k}{nt}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]\right)\left(\dfrac{k}{nt}\left[\dfrac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]-\left[\dfrac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}-h\right]\left[\dfrac{1-\alpha}{\alpha}\right]\right)^{-1/(\alpha-1)}}.$$

This expression tells us, in present values and at respective optimum outputs, the ratio of average total unit costs of the new method to average total unit costs of the old method when the enterprise is indifferent between those methods. It forms the basis for Table I.

II

A. The profit gap:

The difference between the profit required of the new method when inter-

relatedness exists and the profit required in its absence is obtained by subtracting from the left-hand side of (7) the same expression when $t=1$. This gives

$$C\left(1-\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}\right]\right). \tag{14}$$

Substituting for C on the basis of (8) gives for the profit gap

$$\frac{nt}{k}\,[a(1-\alpha)]^{1/\alpha}[v^{1-1/\alpha}]\left(1-\left[\frac{(1+r)^{-nt}-1}{t(1+r)^{-n}-t}\right]\right). \tag{15}$$

B. The profit potential:

This is simply the profit function of the new method. From (5a) modified by (6a), (8) and (9) we have

$$\pi^{*}=[a(1-\alpha)]^{1/\alpha}\left(v^{*1-1/\alpha}\left[\frac{(1+r)^{-nt}-1}{(1+r)^{-1}-1}\right]\left[\frac{\alpha}{1-\alpha}\right]-\frac{hntv^{1-1/\alpha}}{k}\right). \tag{16}$$

A THEORETICAL FRAMEWORK FOR TREASURY DEBT MANAGEMENT

By JACOB COHEN*

In discussing Treasury debt management, a useful approach would seem to be to pose the various alternatives open to the Treasury and then to consider their respective implications. These alternatives can best be formulated in terms of their interest costs. We shall first develop the pure interest-saving model.[1] Then we shall discuss the implications of this model for liquidity. Following that, departures from the interest-saving model will be studied in terms of their effects on liquidity. It is hoped that the relationships that we develop may provide a framework for discussing the major problems of debt management—the selection of the "best" kind of securities and their allocation among different investor classes.

I. *The Pure Interest-Saving Model*

In constructing our interest-saving model, we assume a single debt operation with the Treasury aiming at a given volume of debt revenues. We rule out "printing-press money," direct recourse by the Treasury to the central bank, or the use of compulsion by the Treasury.

There are many alternative ways of treating the transaction between the Treasury and the market. The latter could be thought of as supplying loanable funds or purchasing claims. If the latter approach is followed, there is the question as to how to treat the demand curve. Amounts of securities purchased could be a function of different nominal interest rates with each unit being sold at par, or alternatively they could be a function of different bond prices with securities being redeemable at par. The latter alternative is the one that will be followed. Our demand curve, then, is a demand for claims in terms of the prices of these claims.

If the Treasury is to minimize interests costs, it must offer holders a maximum of special features. This will reduce interest costs by increasing the demand for government securities and/or increasing coefficients of elasticity. It must at the same time be a discriminating monopolist capable of segregating markets for its debt and setting the

* The author is associate professor of economics at Bowling Green State University. He expresses indebtedness to R. A Musgrave for suggestions some years ago.

[1] "Interest-saving" is used synonymously throughout with "interest-reducing."

highest interest yields (lowest prices) in the most elastic markets. The pure interest-saving model thus implies debt which is transferable within a given market but nontransferable between markets.

Perhaps the most important special feature that the Treasury can confer on its obligations is that of liquidity.[2] In our interest-saving model we assume that all issues are redeemable on demand either at the Treasury or at the central bank at fixed prices.[3] Redemption prices would be so set that the redemption of issues before their maturity would never carry any penalty; the holder would always be returned his capital investment and the effective interest rate. This should make it a matter of indifference to the investor whether he is offered short-term or long-term securities.[4] His demand curve for debt should be unaffected by its maturity. It should then be a matter of indifference from the standpoint of the Treasury as to what maturities it sells in a particular debt operation. The Treasury, however, might prefer one maturity length over another in order to avoid bunching refunding dates. We can then assume that the Treasury offers different maturities but that the interest return is the same regardless of maturity.

We are now ready to develop the pure case of Treasury interest-saving. We shall assume that the submarkets for debt are the commercial banks and the nonbank public. These categories would appear to have the most distinctive demand curves. Moreover, debt policy questions focus on these alternatives. Our primary concern throughout this paper will be with the best kind of securities to offer the banks and the nonbank public and the best allocation of the selected issues between these two markets.

In Diagram 1 we have drawn the bank aggregate demand curve to suggest perfect elasticity of demand. We assume that the purchase of assets by the individual bank results in a more or less equivalent increase in its deposit liabilities rather than in a loss of legal reserves. Under these circumstances, at some interest return above the costs of money creation

[2] For a discussion of the various kinds of special features that have been offered by borrowing governments, see my "On the Theory and Measurement of Treasury Interest Saving," *So. Econ. Jour.*, Jan. 1951, XVII, 257 ff., and "The Element of Lottery in British Government Bonds, 1694-1919," *Economica*, Aug. 1953, XX, 237 ff.

[3] The concept of redemption at the central bank suffers from certain ambiguities. The process described is indeed redemption from the standpoint of the holder of these issues. He can cash them in any time he wishes at a price fixed in advance of his purchase. From the standpoint of the central bank which is redeeming issues, the transaction is actually more than that. The central bank acquires ownership of these issues and can presumably resell them in the market designated by the security if it so desires. In future discussions of central bank purchase at fixed prices, we shall mean the same thing by central bank "redemption" and "purchase" of issues.

[4] The investor under these circumstances might prefer long-terms because they avoid the necessity of continual refundings but we can assume this to be a relatively unimportant factor.
DIAGRAM 1 THE BANK AND NONBANK MARKETS FOR SECURITIES

the individual bank should be willing to buy as many government securities as are offered to it. For every dollar of government bonds that it purchases will only require the redemption of a fraction of this amount in order to secure the necessary increase in legal reserves as deposit liabilities expand. The individual and thus the aggregate bank demand curve for debt should thus approach perfect elasticity.[5]

We should expect considerably less elasticity in the nonbank demand curve for securities. As a matter of fact, what perhaps must be explained is why we would expect any positive response in security purchases to reductions in price. The consensus among economists seems to be that savings are relatively insensitive to interest rate changes.[6] When govern-

[5] It may be thought that our assumptions about elasticity are unduly restrictive. Even if the individual bank could not expand in a multiple of its excess reserves, could not the demand curve on the part of the *commercial banking system* approach perfect elasticity because of the possibilities of multiple bank expansion for an entire banking system? Unless some bank or banks had excess reserves to begin with, this would not be so. For without initial excess reserves, the individual bank in the banking system would not purchase a government bond if it had to cash the bond in order to meet subsequent losses in legal reserves. Perfect elasticity in the commercial banking system's demand curve would thus seem to entail perfect elasticity in the individual bank demand curve which in turn depends on the individual bank only having to redeem part of its purchases in order that it may continue to have legal reserves equal to required reserves.

[6] See, *e.g.*, L. R. Klein, "Savings Concepts and Data: The Needs of Economic Analysis and Policy," in *Savings in the Modern Economy*, W. W. Heller, ed. (Minneapolis, 1953), pp. 109, 127-28; H. C. Murphy, "The Role of Interest Rates in a Changing World," *Jour. Fin.*, June 1951, VI, 238 ff; R. I. Robinson, "Monetary Aspects of Fiscal Policy," in *Fiscal Policies and the American Economy*, K. E. Poole, ed. (New York, 1951), p. 71.

ment securities are assumed to be perfectly liquid the demand for securities would presumably show a similar insensitivity. For why would the nonbank public not buy as many securities at high prices (low yields) as they would at low prices (high yields)? Complete liquidity implies that if interest yields increase, low-yielding securities could always be converted into high-yielding issues without loss.

Yet there are several reasons why we would expect a negative slope to our nonbank demand curve. The nonbank public will be induced to buy more securities at low prices than at high prices because interest yields will then be worth the cost and inconvenience of investing. More importantly, the possibilities of a future fall in yields and a subsequent capital gain are increased at lower prices.[7] Finally, if we do not insist on a covariation in yields in other markets, investors will shift into government securities as they fall in price.

In later discussion we shall relax our assumption that nonbank issues are completely liquid. The nonbank demand curve will then shift to the left. For now fewer governments would be purchased at any given security price because of the capital-loss effects of possible increases in market yields. The longer the maturity of the issue offered by the Treasury, the further to the left would nonbank demand lie because of the progressively greater possibilities of capital loss at any security price.

Once we are given the demand curve, a considerable amount of additional information can be read off our diagram. The marginal debt revenue curves indicate the added revenues from the sale of an extra unit of debt. We can also derive the marginal interest outlay curves once we know the demand and marginal debt revenue curves. Let us assume the sale of a one-year security in all markets. The discount from par at which a unit of securities is sold will be equivalent to an annual interest payment. In Diagram 1, such a discount in a given market is suggested by the distance from the horizontal par-value line down to the demand curve for the security (LS and L_1S_1). Distances in turn from the demand curve to the marginal debt revenue curve measure losses on previous units as the Treasury lowers its price to sell additional units. Since the marginal debt revenue curve is identical with the demand curve in the case of the bank market, this distance is shown only for the nonbank market (S_1T_1). The total distance from par to the marginal debt revenue lines (LS and L_1T_1) thus equals the extra interest costs (FR and F_1R_1) from the sale of an additional unit of securities at any given amount of security sales (OR and OR_1) in either market.

[7] Under the assumption of liquidity, there is an asymmetry in the effects of changes in yields on capital gains. Redemption at a fixed price protects the investor against capital loss when yields rise. On the other hand, a fall in yields will raise the market price of higher-yielding issues.

Once the Treasury has decided on the desired amount of debt revenues, the interest-minimizing allocation of debt between the two markets follows automatically. The Treasury will allocate the debt so that marginal interest outlays for each additional dollar raised will be the same in both markets. When the ratio of marginal interest outlays to marginal debt revenues in the bank market is equal to the same ratio in the nonbank market at the same time that the desired volume of debt revenues is being secured, the Treasury will have reached the interest-minimizing allocation. If we transpose terms from one numerator to the other denominator, this formulation is seen to be equivalent to equality in the ratio of marginal interest outlays in the bank and nonbank markets to the ratio of marginal debt revenues in these two markets.[8]

Not only are ratios equal but the terms of each ratio in the last formulation are themselves equal at interest-minimization. Marginal debt revenues in both markets will be equal and similarly for marginal interest outlays. This is illustrated by the equality of SR and T_1R_1 and the equality of FR and F_1R_1 in Diagram 1. The explanation lies in the fact that the marginal debt revenues and marginal interest outlays from any allocation of debt in a given market always sum up to the face value of the security (this face value being the same in both markets).

We can also tell what prices of securities and interest yields will be set in the two markets. Security prices will be highest in the less elastic market. Thus the Treasury will sell securities in the nonbank market for S_1R_1 and for SR in the bank market.

The argument can now be developed with greater generality by means of indifference curve analysis. The R curves in Diagram 2 represent indifference revenue curves. Each of these curves shows alternative combinations of bank and nonbank debt which yield the same amount of debt revenues. Curves farther to the right indicate successively higher levels of debt revenues. The successive slopes of each curve proceeding downwards reflect the behavior of marginal debt revenues in the bank and nonbank markets as allocations to the former market are increased. When relatively great allocations of debt are made in the nonbank market, marginal debt revenues there will be relatively low as compared with marginal debt revenues in the bank market. As a result, additions of successive units of bank debt will require the subtraction of rela-

[8] Stated algebraically, for interest minimization,

$$\frac{MIO_b}{MDR_b} = \frac{MIO_n}{MDR_n}$$

where the subscripts b and n indicate the bank and nonbank markets respectively. Transposing terms we get,

$$\frac{MIO_b}{MIO_n} = \frac{MDR_b}{MDR_n}.$$
DIAGRAM 2 THE INTEREST-MINIMIZING ALLOCATIONS

tively large amounts of nonbank debt if total debt revenues are to be maintained on the same level. On the other hand, when relatively large allocations of debt are made to the bank market, marginal debt revenues from nonbank debt will be relatively high. Additions of bank debt will then require smaller reductions of nonbank debt in order to keep debt revenues constant. The curves are thus drawn convex from below.[9]

The indifference cost curves (C_1, C_2, etc.) respectively represent combinations of issues sold to the bank and nonbank public which carry the same total interest costs. The successive slopes of a given curve reflect the behavior of marginal interest outlays in the two markets. When relatively large allocations are made in the nonbank market, marginal interest outlays in that market will be relatively large as com-

[9] We have drawn the indifference revenue curves as negatively sloping. There may also be positively sloping sections to these curves. Two factors will have to be present for positively sloping sections in the upper portions of the revenue curves. First, the nonbank demand curve must have regions of inelasticity and negative marginal debt revenues. Second, desired revenues must be such that the onset of negative marginal revenues prevents the raising of the entire amount from the nonbank public. The R_1 curve has been drawn to suggest an absence of the second condition. Desired revenues are assumed low enough to permit the raising of all desired revenues from the nonbank public. The R_2 and R_3 curves terminate short of the nonbank axis because additional units of nonbank debt are assumed to carry negative marginal revenues. Since we assume perfect elasticity in the bank demand curve, there is not a similar possibility of positive slopes in regions of large amounts of bank debt and small amounts of nonbank debt.

pared with marginal interest outlays in the bank market. The addition of one more unit of bank debt will then require very small reductions in nonbank debt in order to keep the level of interest costs constant. When relatively large allocations are made to the bank market, marginal interest outlays will be relatively high in that market. Large reductions in nonbank debt then will be necessary with the addition of successive units of bank debt if interest costs are to be kept on an indifference level. The indifference cost curves are thus drawn concave from below.

The apparent bunching of the indifference cost curves on the nonbank vertical axis results from increasing marginal interest outlays on nonbank debt as sales to the nonbank public increase. Given increases in the level of interest cost will be represented by progressively smaller increases in the amounts of nonbank debt. On the other hand, the behavior of marginal interest outlays in the bank market will result in the same given increase in interest costs being represented by constant increases in the amounts of bank debt. Thus the indifference cost curves appear to flatten out as we move up the indifference cost map.

In the analysis of Diagram 1, the interest-minimizing allocation occurred when the ratios of marginal debt revenues in both markets equaled the ratios of marginal interest outlays. Expressed in indifference-curve terms, interest-minimization for a given level of debt revenues occurs at tangency of the relevant indifference revenue curve with some one indifference cost curve. At tangency, the ratios of marginal debt revenues and the ratios of marginal interest outlays must be equal. As would also be expected, the slopes of each curve at tangency equal unity ignoring algebraic sign. Marginal debt revenues are equal and similarly for marginal interest outlays.

The assumption of perfect elasticity in bank demand results in the tangency points of successive pairs of indifference cost and indifference revenue curves lying along a horizontal straight line as suggested by points A_1, A_2 and A_3 in Diagram 2. Minimization of interest costs for successively higher levels of debt revenues are effected without change in the amount of nonbank debt but with increasing amounts of bank debt.[10] If the bank demand curve were less than perfectly elastic but more elastic than the nonbank curve, the successive tangency points would lie on a positively sloping line the slope of which would be such that, for each increase in total revenue, the increase in bank debt would exceed the increase in nonbank debt.

[10] This can also be seen from Diagram 1. The assumption of perfect elasticity in bank demand results in the ratio of marginal interest outlays to marginal debt revenues being constant no matter what allocation is made to the bank market. There is only one possible allocation of debt to the nonbank public which can yield the same ratio Interest-minimization thus implies a unique allocation of debt to the nonbank public regardless of the amount of revenues borrowed.

This, then, is the pure interest-saving model, based on the maximum use of special features by the borrowing or refunding government. The alternate allocations of debt suggested by this model will have alternative implications for the level of liquidity and the level of interest costs. We must now discuss these implications.

II. *Interest Costs and Liquidity: The Interest-Saving Model*

The Primary Liquidity Relation

On the basis of Diagram 2 we shall develop the basic relationship between variations in interest costs and liquidity for a given level of debt revenues.[11] This relationship is initially described by the L_1 curve of Diagram 3. We shall refer to it as the primary liquidity relation. Numerical values have been assigned to various points on the axes of the diagram in order to facilitate the exposition. Underlying these values are the following assumptions. Desired debt revenues in the given debt operation amount to $10 billion. The bank demand curve is perfectly elastic at the security price of $95. Five million units of securities can be sold to the nonbank public at a price of $99 and every one dollar reduction in price will be accompanied by a five million increase in the number of units demanded.

The L_1 curve begins at the amount of bank sales corresponding to the interest-minimizing allocation of debt. On the basis of our assumed values, equality of marginal debt revenues and thus interest-minimization occurs at a level of liquidity (bank borrowing) of $8,545 million and interest costs of $495 million. Movements down the L_1 curve describe the relationship between reduced sales of issues to the banks and increased levels of interest cost. Let us say that the desired volume of debt revenues of $10 billion are signified by the R_1 curve of Diagram 2. Movements down the L_1 curve are then another way of looking at movements up the R_1 curve from A_1 in Diagram 2. As one moves up the R_1 curve, it is intersected by higher indifference cost curves implying that increased allocations to the nonbank public are associated with higher levels of interest cost. More than this, because of increasing marginal interest outlays on nonbank debt and because more units of nonbank debt are successively substituted for bank debt, given reductions in sales to the banks will be accompanied by increasing increments in interest costs. The curve L_1 is thus drawn convex from below. The

[11] The two different senses in which we shall employ the concept of liquidity should be pointed out. When we speak of the level of liquidity or the liquidity effects of issues, we shall be referring to the effects of debt operations on the money supply and/or the volume of money-substitutes. When used to suggest a quality of issues themselves, as for example, when we speak of highly liquid issues, the term liquidity will denote their ease of redemption without loss.
Diagram 3. The Primary Liquidity Relation Corrected for Treasury and Central Bank Redemption of Nonbank Issues

degree of convexity depends on the relative elasticities of bank and nonbank demand. The more elastic the nonbank demand curve relative to the bank demand curve, the steeper the relation will be. At its extreme right, the curve ends up at the horizontal axis, indicating zero sales to the banks at interest costs of $3,900 million.

The issues sold to the nonbank public have a high degree of liquidity because of their assumed redeemability on demand either at the central bank or the Treasury. The actual redemption of issues will have both an interest-cost and liquidity effect. These effects will differ depending on the agency of redemption. We shall explore them beginning first with redemption at the Treasury.

The Primary Liquidity Relation Corrected for Treasury Redemption of Nonbank Issues. Each point on the primary liquidity relation (L_1) indicates not only the money- and interest-cost effects of a given debt allocation but also specific security prices for bank and nonbank debt. We shall derive the liquidity relation corrected for Treasury redemptions

by determining the volume of redemptions at certain selected security prices and calculating their monetary and interest-cost effects.

Let us begin with the security price of $97 for nonbank issues (and $95 for bank issues). These are the prices for the interest-minimizing liquidity point A on L_1. For at these security prices, marginal debt revenues will be the same on nonbank debt ($95) as on bank debt.

Let us now assume (quite arbitrarily) that 20 per cent of the issues sold to the nonbank public at any given security price will be presented for redemption at the Treasury. The effect of such redemptions when sales are initially made at $97 is for $291 million of bank borrowing to be substituted for nonbank borrowing with a net increase in interest costs of $6 million. For if desired debt revenues are to be maintained by the Treasury, the latter will now have to borrow from the banks in order to redeem the nonbank issues presented for redemption. The resultant corrections for the effects of Treasury redemption are shown by the A_1 point on the L_1' relation. In similar fashion we can derive points B_1 and C_1. The latter point lies to the left of the corresponding point on L_1 because as soon as the price of nonbank issues falls below that of bank issues, the redemption of nonbank issues at the Treasury results in an increase in the money supply but a decrease in interest costs.

The Primary Liquidity Relation Corrected for Central Bank Redemption of Nonbank Issues. In treating the alternative possibility of nonbank redemption at the central bank, we assume that at any given security price the volume of redemptions at the central bank will be similar to the volume of Treasury redemption when the latter is the agency of redemption. These redemptions should have exactly the same monetary effect as redemptions at the Treasury. Instead of the Treasury issuing substitute amounts of debt to the commercial banks, the central bank will be monetizing equal amounts of nonbank debt by its purchases. The effect of central bank redemptions should then cause the liquidity points A, B, C, and L_1 to move up to the same level as that of A_1, B_1, C_1 respectively on L_1'.

The interest-cost effects of central bank redemptions should be quite different, however. Under Treasury redemption, interest costs on the redeemed nonbank debt are, of course, cancelled. But this decrease in interest costs is offset by the increase in interest costs on the substitute debt sold to the commercial banks. Thus, for example, at A_1, interest costs on the nonbank debt declined by $9 million as a result of Treasury redemption. But the substitute bank debt increased interest costs on commercial bank debt by $15 million. As a result, point A_1 on L_1' showed a $6 million net increase in interest costs as compared with point A.

Under most arrangements, the earnings of the central bank can be assumed to revert in substantial part to the Treasury. The interest costs on nonbank debt redeemed by the central bank are thus in effect cancelled also.[12] At the same time, since the central bank rather than the Treasury has redeemed these nonbank issues, it is unnecessary for the latter to sell additional amounts of debt to the commercial banks in order to maintain desired revenues. The essential difference between central bank and Treasury redemption is then the saving of interest costs on substitute commercial bank debt when the central bank is redeeming issues. Points A_2, B_2, C_2 on L_1^c (which is L_1 corrected for the effects of central bank redemption) lie directly to the left of A_1, B_1, C_1 by the amounts of these savings. In Diagram 3, they are to the left by $15 million, $56 million, and $106 million, respectively.

If we were to change one of our original assumptions and assume that the Treasury could borrow directly from the central bank when it (the Treasury) redeemed nonbank issues, the dissimilarities between the two cases of central bank and Treasury redemption would disappear.[13]

We might think of the corrected primary liquidity relations as the Treasury "housekeeping" relations. For they are of immediate significance to the Treasury, indicating the true costs to the Treasury of different initial bank-nonbank allocations. Such housekeeping relations do not reveal the entire story about the monetary effects of alternative allocations. For there are additional monetary effects from possible bank expansion, from nonbank purchase and holding of issues, and from interest costs themselves. The relation now to be developed, since it attempts to comprehend all liquidity effects, can be called the "over-all relation."

The Over-all Relation

We shall now assume that all redemptions take place at the central bank. We have thus reproduced in Diagram 4 the L_1 and L_1^c relations of Diagram 3. The first additional monetary effect results from excess reserves automatically provided the commercial banks by redemption of nonbank issues at the central bank. These excess reserves will be less than the amount of nonbank redemptions because of the the concomitant increase in required reserves or cash withdrawals. If we make the assumption that monetization of nonbank issues takes the form of

[12] While not strictly correct, we shall for purposes of simplicity assume that gross central bank earnings from government debt revert to the Treasury.

[13] Or alternatively, if we assumed that interest earnings of central banks were true costs to the Treasury, differences between our corrected relations would again vanish.
DIAGRAM 4. THE OVER-ALL RELATION

deposit liabilities, and that reserve requirements are 20 per cent, every $100 of nonbank redemption will provide the commercial banks with $80 of excess reserves. At minimum interest costs of $486 million, the associated volume of nonbank redemptions will be $291 million.[14] The resultant increase in excess reserves will be $232.8 million. Assuming a coefficient of bank expansion of 5, the potential amount of assets that can be acquired by the commercial banking system on the basis of these excess reserves will be $1,164 million. Adding this amount on to the $8,836 million shown at A_1 we secure the first point on the new L_1^n relation which thus begins at $10,000 million. In similar fashion we can derive the two other values shown on this relation. The horizontal slope of this relation is explained by our assumptions. Twenty per cent of initial nonbank allocations multiplied by the coefficient of expansion

[14] All monetary effects from given bank-nonbank allocations will be plotted at the corrected levels of interest cost as these were arrived at in the preceding section on central bank redemption of nonbank issues

of 5 will always give us a value equal to these initial nonbank allocations. Superimposing these values on initial allocations to the banking system must necessarily give us values equal to desired debt revenues of $10 billion.

As the next stratum in monetary effects, we must consider the redemption by the commercial banks of their own initial holdings of governments. We shall again (arbitrarily) assume that 20 per cent of their holdings will be redeemed at the central bank for the purpose of further asset expansion.[15] At the interest level of $486 million, a 20 per cent redemption will amount to .20 times $8,545 million or $1,709 million.[16] Assuming again a bank coefficient of expansion of 5, total possible asset acquisition could be $8,545 million. The L_1^b relation cumulates this amount onto the previous $10,000 million and thus begins at $18,545 million. The steep slope of this relation when other values are plotted is explained by the diminution in commercial bank purchases and thus in potential excess reserves as we proceed to the right on the diagram.

Interest costs may exert a monetary effect in themselves. These are suggested by the L_1' relation. As allocations to the nonbank public increase beyond the interest-minimizing allocation, the level of interest costs will rise. If such increases in interest costs are not financed by taxation, the desired level of debt revenues must increase beyond the level implied by the primary liquidity relation. In such a case, bank borrowing may also increase.

Let us assume that the corrected minimum interest cost level of Diagram 4—$486 million—can be financed out of taxation (or desired revenues of $10 billion). Interest costs in excess of this amount will either have to be financed out of taxation or borrowing. We shall assume that half of the excess in interest costs is financed by borrowing and that this borrowing is divided between bank and nonbank sources in the same proportion as initial bank-nonbank allocations. The problem entailed by the fact that extra borrowing will have interest costs of its own will be circumvented by assuming that they too are financed by taxation.

On this basis the new liquidity relation begins at $18,545 million at interest costs of $486 million. At interest costs of $824 million, the

[15] These redemptions will be over and above the redemptions necessitated by the initial bank purchase of governments. Such purchases would increase the deposit liabilities of the banks or their currency withdrawals. In either case, the commercial banks would find it necessary to cash in some of their governments

[16] The redemption of bank issues at the central bank should reduce true interest costs just as nonbank redemptions did The L_1^b relation should thus begin to the left of the L_1^a relation. For simplicity's sake, however, we shall ignore this shift in the relation and assume that it also begins at $486 million.

excess of interest costs amounts to $338 million half of which is assumed to be financed by borrowing. At this level of interest cost, approximately 47 per cent of initial Treasury borrowing was from the commercial banks. Applying this percentage to $169 million and multiplying it by the coefficient of expansion of 5 gives us total possible monetary effects of $397 million. Superimposing this on the L_1^b value of $14,720 million, results in the plotted value of $15,117 million. In a similar way, other values can be arrived at.[17]

Purchases by the nonbank public have liquidity effects apart from the effects of redemptions. Such purchases may be financed out of idle cash balances or out of funds borrowed from the banking system. The L_1^d relation assumes that 20 per cent of nonbank purchases will be financed in these ways. In order to cumulate this liquidity effect onto the others already discussed we shall assume that a reduction in idle cash balances is equivalent in economic effect to an increase in the actual money supply and can thus be treated in the same fashion. The liquidity axis should then be interpreted as measuring both increases in the actual money supply and decreases in idle cash balances. On this basis the L_1^d relation begins at $18.836 and terminates at $12,000 million.

Issues retained by the nonbank public and not redeemed will exert a liquidity effect of their own. The moneylike quality of such issues may encourage the nonbank public to hold smaller amounts of idle cash balances. We shall assume that each $100 of retained nonbank issues results in a $20 decrease in holdings of idle balances. We thus calculate 20 per cent of retained nonbank issues at the selected interest cost levels in order to arrive at the L_1^l relation. This can also be regarded as the "over-all relation" since it has cumulated all the previous relations.

The height and slope of our over-all relation has been determined by the assumptions we have made about the relative elasticities of bank and nonbank demand, the ratios of bank and nonbank redemptions to initial purchases, the coefficient of bank expansion, the percentage of increases in interest cost financed by bank borrowing, the per cent of nonbank purchases financed by new money, and the cash-balances effect of purchasing and retaining nonbank issues. These are, of course, wholly arbitrary assumptions without empirical basis. Variations in them will produce an unlimited number of relations. The greater the elasticity of nonbank demand and the amount of banks' redemption of

[17] An alternative assumption would have considerably more of a flattening effect on the L_1^c relation. If half of the increases in interest costs were financed by a fixed percentage of bank borrowing, monetary effects would increase with increases in interest costs rather than decreasing.

their own holdings and bank asset expansion on the basis of the resultant reserves, the more negatively sloping will be our over-all relation. The greater the importance, on the other hand, of the monetary effects of interest costs, nonbank purchases, retentions, redemptions and bank expansion on the basis of the resultant increases in reserves, the more nearly positive or the more positively sloping will be the over-all relation.

While its proof may be more intuitive than empirical, we shall consider the over-all relation to be a downward sloping one, as suggested by our hypothetical example. The implications of such a relation seem more reasonable than the implications of a flat or rising relation. For a negatively sloping relation implies that a dollar of nonbank debt will have less over-all monetary effects than the dollar of bank debt for which nonbank debt is being substituted.

III. *Interest Costs and Liquidity: Departures from the Interest-Saving Model*

Illiquid Nonbank Issues

The Treasury will depart from the interest-saving model by offering illiquid issues to the nonbank public. Issues may still be more liquid than any other paper claim but the comparison is now with the "most liquid" type of governments. Neither Treasury nor central bank redemption will be assumed to be offered the nonbank public. Liquidity will now only be provided by the marketability of nonbank issues within the nonbank sector. Bank issues are still assumed to be redeemable on demand at the central bank.

The maturity lengths of securities now become of significance for the first time. Depending on the time to maturity, an illiquid nonbank issue will have more or less liquidity. Thus the nonbank demand curve should lie the farther to the left the longer the maturity of the issue sold.[18] If only a single maturity is offered the nonbank public in a given debt operation, there will be a unique primary liquidity relation for each alternative length of maturity. The longer the maturity, the farther to the right on a map of liquidity relations would the appropriate relations lie.

The lower terminal point of many (if not all) of these relations would possibly occur at some positive level of bank borrowing. Assuming the raising of the same volume of debt revenues as in the case of L_1 relation, the more limited demand for illiquid issues is likely to result in demand inelasticity and negative marginal debt revenues before the

[18] See our discussion of the nonbank demand curve, pp. 322-23 above

debt is entirely allocated to the nonbank public.[19] This will be increasingly true as maturities lengthen. We should thus visualize a series of relations, each beginning to the right of the previous relation but having a lower terminal point above and to the left of each of those representing a shorter maturity.

If now we were to remove the marketability feature of nonbank issues and assume that they are nonmarketable both within and without the nonbank sector, we should reach the ultimate in illiquidity. The term nonmarketability is used strictly and does not imply the option of redemption at the Treasury before maturity. With the exception of issues with very short maturities, such nonmarketable issues would probably be unsellable except at very low prices.

The offering of many different maturities in a given debt operation would probably result in a composite primary relation lying below any of the primary relations based on the offering of relatively illiquid issues in a single maturity only. For the broadening of the nonbank market for debt by the offering of many maturities would lower the average yield (raise the average issue price) for any given amount of nonbank borrowing. In this way, the aggregate interest costs associated with a given level of money creation (bank borrowing) should be lowered. We shall refer to this composite primary relation as the "L_2 relation."

A composite relation will impose certain restraints on the security prices offered by the Treasury. These various maturities for marketable issues would have market prices. We would anticipate some regularity in the relationship of market yield (market price) and maturity. If long-run interest expectations are for rising rates, this would result in a "Treasury yield curve" which rose with length of time to maturity. Or (apart from interest expectations), if there is a preponderance of demand from investors wishing to maintain a high degree of liquidity the yield curve would be a rising one. The Treasury will then have to be mindful of the market pattern of rates when it sets a price on a given maturity. Variations in one security price will require consistent variations in those for other maturities as well.

There can be an indefinite number of L_2 relations since at alternative patterns of rates the Treasury may limit its sale of certain maturities. Thus it may offer as many long-terms as it can hope to sell but underallot short-term issues. Each weighting of maturities will produce its distinctive interest-cost level for given amounts of bank-nonbank borrowing and thus its own distinctive liquidity relation.

[19] The likelihood of negative marginal debt revenues before the debt is entirely lodged with the nonbank public is increased by the sale of illiquid rather than liquid issues in the same way that this likelihood is increased by increases in the volume of desired debt revenues (see footnote 9, above).

It is of some importance to decide how the primary and over-all relations based on illiquid nonbank issues compare with those based on liquid issues. Certainly we should expect the L_2 primary relation to lie above and to the right of the L_1 relation. For the composite demand curve for illiquid issues of various maturities would lie to the left of the demand curve for a perfectly liquid issue on the basis of which the L_1 relation is constructed.

It is possible, however, that the *demand to hold* securities may be the same whether liquid or illiquid issues are sold. Allowing for the redemptions made possible by liquid issues (and which by assumption are not possible for illiquid issues), the demand curves to hold may be identical or be greater for illiquid issues. Just how the nonbank demand to hold for illiquid issues compares with the demand curve to hold for liquid issues has been a major issue in debt management. In Section IV of this paper we shall indicate some of the arguments that have been advanced for and against there being a greater demand to hold for illiquid issues.

Illiquid Bank Issues

As our next departure from the interest-saving model, let us consider the implications of variations in the liquidity of bank issues. Up until now, they have been assumed to be redeemable on demand at fixed prices at the central bank. They were thus equivalent to legal reserves. Let us now assume that bank issues provide only an eligible collateral for loans from the central bank. Given an aversion to central bank borrowing and its direct variation with the amount of bank borrowing, the bank demand curve might shift to the left and depart from perfect elasticity. It would probably begin at some higher interest yield than the previous bank demand curve and become progressively less elastic. The essential modifications in our liquidity relations would not appear to be substantive ones, however. Assuming the same alternative types of nonbank issues, the primary liquidity relations should now begin at lower levels of money supply and higher levels of interest cost. The reason for this is that modifications in the bank demand curve will result in minimum interest costs being associated with larger allocations to the nonbank public and higher rates of interest on both bank and nonbank debt. The new liquidity relations should continue downward and to the right of the former relations. The relations involving illiquid nonbank issues should terminate at the same level of liquidity as for the primary L_2 relation but at higher levels of interest cost. In the case of liquid nonbank issues, the liquidity relation should have the same terminus as L_1. For at zero sales to the banks (as this terminal point implies) the assumed increases in bank interest costs will be ineffective.

This revised relation will then be shorter and steeper than the former L_1 relation.

We have now discussed the major choice confronting the Treasury in choosing a liquidity relation. It may emphasize the sale of liquid issues or it may stress illiquid issues. In addition, there is the question of just what liquidity point (interest structure) to select once a decision has been made about the liquidity relation. These issues have been extensively debated in recent years. In the next section we shall attempt to formulate this debate in terms of our analysis. This will also provide a convenient summary to our argument.

IV. *The Issues in Debt Management*

The Treasury was criticized for many years, down to the time of the famous "accord" with the Federal Reserve authorities in 1951, for selecting liquid issues and setting low rates on these issues. In terms of our analysis, it was criticized for selecting low-lying primary relations and choosing points up and to the left on these relations. It was suspected that these decisions were motivated by a concern for interest costs. As a consequence, debt management was said to have been responsible for undesirable liquidity effects.

The liquidity relations selected by the Treasury in this period can be described as a mixture of the two basic types of relations on which we have built our theoretical analysis. We can think of them as L_2 relations modified by some of the characteristics of the L_1 relations. Thus nonmarketable issues (then and now) have provisions for redemption at the Treasury at the option of the holder before maturity and thus have much of the liquidity of L_1' issues. They are not completely liquid, however, because of the various waiting periods before redemption and the interest-rate penalties against early redemption. The marketable part of the debt may be viewed as L_2 issues having a high degree of liquidity because of fairly rigid support of the prices of marketable issues by the central bank.[20] We suggest the type of issues offered by the Treasury by the L_1 relation of Diagram 5

The rigid support given to market prices by the central bank tended in general to stabilize the market yield structure prevailing at the outset of the second world war. The liquidity point on a given liquidity relation is automatically selected when yields on new issues are set according to the prevailing structure of yields. Sales to the nonbank public are then determinate and so are residual sales to the banks. Total interest costs follow from this allocation and from the yields paid in the

[20] During the period under discussion, the degree of support underwent various modifications. Our analysis here and elsewhere will involve an obvious simplification of actual debt history.

two markets. We represent the money supply and interest-cost effects of the liquidity point selected by the Treasury by point A.

Our theoretical framework was constructed on the basis of a single debt operation. Redemptions at the Treasury or the central bank were assumed to be a portion of issues sold during the same debt operation. More realistically, in the course of a given debt period, issues sold in previous debt operations may be presented for redemption at the Treasury or sold to the central bank. The moving up of liquidity relations as a result of the unloading of "old" issues will probably be more significant than the moving up effects of redemption or sale of new issues. This is increasingly true as the debt outstanding grows and comes to constitute an ever larger multiple of the current debt operation. Certain inherent contradictions resulting from the mixing of L_2 and L_1 features tended to increase the rate of redemption of old marketable issues in the period under consideration. Unqualified central bank support was given to a term-structure of yields which rose with time to maturity. This encouraged the sale to the central bank of long-term issues as their term to maturity shortened. Moreover, bank and nonbank markets were not rigidly stratified. This resulted in nonbank holders "free-riding" by selling issues to the commercial banks whose purchase the banks had originally financed.

The sale of liquid issues runs the risk of some outside shock occurring which will precipitate a wholesale unloading by the nonbank public. For a considerable period after issues are sold, there may be a strong demand to hold issues. But once higher prospective returns develop in other markets, nonbank holders will be tempted to redeem issues acquired in past and current debt operations. This is indeed what happened in the postwar period. The L_1^{c+t} relation of Diagram 5 suggests the resultant moving up of the primary relation. The fact that liquid issues quite possibly postponed monetary effects until the end of the war, was not regarded by critics of debt management as an adequate defense of low-lying primary relations in the war period. It was just in the postwar period that a containment of liquidity effects was most necessary and desirable.[21]

As would be suggested by our framework, the moving up of the primary relation exerts an opposite effect on interest costs and money creation. The yields paid by the Treasury on nonbank debt exceeded those paid on bank debt. The sale (redemption) of nonbank issues resulted in either increased holdings by the central bank or substitute borrowing from the commercial banks. In either case, true interest costs must have declined. The liquidity point A thus moved upward to the

[21] *Cf* Woodlief Thomas, "Lessons of War Finance," *Am. Econ. Rev.*, Sept. 1951, XLI, 628.
DIAGRAM 5 TWO ALTERNATIVE DEBT POLICIES COMPARED

left[22] to a position such as suggested by A_1 on L_1^{c+t}. It would seem possible, then, that the Treasury selected liquid issues because of the interest-saving effect of nonbank redemptions. This is not likely, however. The Treasury could have secured the A_1 level of interest costs more directly by selling illiquid issues to the nonbank public thus forcing itself to borrow larger amounts from the banking system. A more reasonable hypothesis would seem to be that the Treasury selected a low primary liquidity relation in order to reduce effects on the money supply within the limits set by the prevailing yield structure. Since the primary relations are downward sloping, it is of course true that selection of a low primary relation also meant that interest costs were simultaneously being reduced for the selected level of liquidity. Interest costs were not being absolutely minimized, however. The interest-saving intentions of the Treasury are perhaps most clearly revealed by its adherence to the prevailing market structure when it conducted intensive borrowing operations. If it had not adhered to this structure it could have moved even farther down the selected relation and have been responsible for even smaller increases in the money supply. That this was not done is

[22] The only exception to this results from imperfect stratification of bank and nonbank markets. When the nonbank public sold its holdings to the commercial banks, the monetary effect was present without the interest-cost effect. To this extent the A liquidity point moved straight up rather than to the left. The same would be true of any other liquidity point, except that liquidity points indicating initially higher yields on bank than on nonbank debt would now move straight up instead of moving to the right. The removal of stratification is thus analogous in its effects on the liquidity relation to that of Treasury redemption as compared with central bank redemption of nonbank issues only in a more decided way. (See Diagram 3.)

probably explained by an aversion to higher levels of interest cost.

Failure to proceed farther down the relation made this saving of interest more apparent than real, according to some critics.[23] For the liquidity points selected so increased the money supply that the price level was bound to be affected. The Treasury in succeeding operations thus was compelled to increase its money borrowing in order to finance a given level of real expenditure.[24] The relevant primary liquidity relation would move to the right. Maintenance of the same yield structure on new borrowing or refunding operations would then require higher interest costs as well as greater initial amounts of bank borrowing.[25] Treasury interest costs might have been lower in the long run, according to these criticisms, if less liquid issues had been used and higher yields had been paid.

Those who wished to restrict the monetary effects of Treasury debt operations would have selected a primary liquidity relation of the type suggested by L_2 in Diagram 5. The subscript indicates that it would have been more closely akin to the L_2 relation of our theoretical analysis than to the L_1 relation. Of the many possible variants of composite L_2 relations, it would probably have weighted long-terms more heavily than short-terms. Its initial distance above the L_1 relation of Diagram 5 is explained by the relative illiquidity of the issues offered. Many degrees of illiquidity could have been offered in the place of rigid support. There could have been support with adjustable "pegs," market stabilization, or just sufficient support to maintain orderly markets.[26] Orderly markets would have called for the stabilizing of key issues for uncertain durations. Finally, there could be complete illiquidity which would obtain if the central bank not only failed to support securities at any

[23] See, for example, Lester V. Chandler, "Federal Reserve Policy and the Federal Debt," *Am. Econ. Rev*, Mar. 1949, XXXIX, 427.

[24] Under certain circumstances it is conceivable that desired debt revenues would not increase. Price-level increases would raise the level of money national income. Tax receipts would then rise If the income elasticity of tax receipts were sufficiently high, desired debt revenues would actually decrease. For this to happen, however, the income elasticity of tax receipts would have to exceed the income elasticity of government expenditures by at least the initial ratio of government expenditures to taxes This follows from the necessary excess of government expenditures over tax receipts for there to be a deficit in the first place. With a given change in money national income then, the same percentage change in taxes and expenditures would actually result in a greater absolute change in expenditures and thus a greater deficit.

[25] The extent to which bank borrowing and interest costs respectively increased would depend on the repercussions of a higher money national income on the nonbank demand curve for governments. The greater the increase in demand, the greater the increased allocation to the nonbank public at prevailing yields and the greater the increase in interest costs and the smaller the increase in necessary bank borrowing.

[26] *Cf* Robert V. Roosa, "Integrating Debt Management and Open Market Operations," *Am. Econ. Rev.*, Proceedings, May 1952, XLII, 218 ff.

time but even took the selling side of the market when inflationary circumstances warranted it.[27]

Let us assume that central bank support would be limited to the provision of orderly markets. This might be taken to mean the supporting of market yields at approximately the level of yields offered on new issues. As yields were increased on new issues under the proposed policy, prices of outstanding issues would fall away from their issue prices. Nonbank holders could only shift out of debt and into cash by taking a capital loss on their holdings. In addition, the effect of increasing yields might deter sales to the central bank by generating a vague uncertainty. If the private yield structure should be "sticky," the advantages to lenders of cashing in their holdings for the purpose of alternative investment would also be reduced.[28]

For these reasons, the moving-up of the L_2 relation was expected to be much less substantial than the moving up of the L_1 relation. Some moving up in the L_2 relation was probably regarded as inevitable. Certain nonbank holders of marketable issues would be willing to take capital losses. Holders of nonmarketable issues might actually be encouraged to redeem as market yields rose. But on the whole, holders of marketable issues were expected to be deterred from shifting out of debt.

The higher the level of yields offered on new issues, the greater would be potential capital losses and thus the greater would be the locking-in of outstanding issues. Thus the farther down on the L_2 relation that the selection of the liquidity point was made, the smaller would be the moving-up effects. For this reason the L_2 relation corrected for nonbank redemptions and sales to the central bank—L_2^{c+t}—is drawn as a steeper relation than L_1^{c+t}.

The payment of higher yields as suggested by the critics of debt management might have taken the form of selecting a liquidity point such as point B on the L_2 relation. It represents the same initial allocation between the banks and the nonbank public as was secured by the use of the A liquidity point. The sale of the same dollar volume of debt to the nonbank public when illiquid rather than liquid issues were offered would necessarily require the payment of higher yields. The limited moving-up of this point as a result of illiquidity and higher yields is suggested by B_1 on L_2^{c+t}.

If the proposed policies were effective, they would have reduced the volume of excess reserves automatically made available to the banks

whenever the nonbank public sold issues to the central bank. Restrictive policies were also aimed at curbing bank expansion of credit on the basis of the banks' own holdings of governments. This would have been done by removing support prices from bank issues as well as nonbank issues and by offering increased yields on new issues. If private yields showed rigidity, this would have been an additional factor reducing the attractiveness for banks of cashing in their holdings. By lowering reserve requirements or through limited open-market operations it would still be possible to have banks play the role of residual lender to the Treasury.

In sum, the proposed policies would have attempted to minimize the over-all liquidity relation and to choose a satisfactorily low level of liquidity on this relation by substituting relatively illiquid bank and nonbank issues for liquid issues and by paying higher yields. According to one school of thought, relatively small increases in yields combined with only the provision of orderly markets for securities, would have had the effect of securing substantial reductions in the money supply.[29]

It is not certain, however, that these policies would have succeeded. For it is possible that rising yields would have occasioned expectations of further increases and thus have encouraged sales to the central bank despite the incurrence of capital losses. Uncertainty and confusion might have disappeared after the market had adjusted itself to flexibility. The private yield structure may be much less rigid when the employment of devices equivalent to higher interest rates is considered.[30] As a result, the over-all liquidity relation based on relatively illiquid issues might have been above one based on liquid issues. While higher yields would have had the effect of moving-down the over-all relation, if the moving-up effects of illiquid issues had been substantial enough, the over-all level of increase in the money supply could have exceeded the level based on lower yields on liquid issues. The period after the Treasury-Federal Reserve accord offers a somewhat limited test of this issue. For the subsequent modifications of policy were relatively moderate.[31] And yet, in the twelve-month period after the accord, the increase in the money supply greatly exceeded the increase for approximately nine months before the accord.[32] Analysis of this increase would indicate that slightly falling market yields did not succeed in locking-in the nonbank holdings of life insurance companies and other major in-

stitutional holders.[83] Nor did they prevent a considerable expansion in bank loans and investments although this expansion was related to variations in the monetary gold stock rather than to central bank absorption of governments.[84]

It would be maintained by some that issues were not made sufficiently illiquid and that yields did not advance high enough to curb monetary effects. To curb increases in the money supply, interest rates should advance just as far as is necessary to achieve the desired reduction without any consideration at all to the effect on the prices of government securities.[85] Primary liquidity relations which began far to the right and liquidity points far to the right on these relations would have been selected if necessary under this policy. Desired debt revenues could then have been largely secured from the nonbank public without any moving-up effects.

Implicit in this analysis is some assumption about the lower terminus of liquidity relations based on illiquid issues. It is apparently assumed that the L_2 relations will terminate at the horizontal interest cost axis or close to this axis. In this way, desired debt revenues could be secured in the main from the nonbank public as long as the Treasury were willing to pay the necessary interest return. It is possible, however, that the selecting of highly illiquid issues would result in relations that not only began far to the right but terminated at positive levels of bank borrowing. Negative marginal debt revenues might make it impossible to lodge most of current borrowings or refundings with the nonbank public.[85a] In this way residual allotments to the banking system would be increased. The failure of the relation to move up would be somewhat neutralized by the higher initial allocations to the banking system that it made necessary.

If we grant the implicit assumption that the primary liquidity relations for illiquid issues will terminate close to the horizontal axis, then another difficulty would seem to present itself. Extensive movements to the right, if necessary to curb monetary effects, would cause interest costs to increase sharply. If no weight is given to such interest costs then the argument would seem to be a logical one. But interest costs

[83] Statement of C. R. Whittlesey, *Hearings before the Sub-committee on General Credit Control and Debt Management*, *op. cit.*, pp. 699 ff.

[84] *Ibid.*, p. 710.

[85] Friedman, "Comments on Monetary Policy," *op. cit.*, p. 187; *Hearings*, *op. cit.*, p. 732.

[85a] Our analysis would apply even if securities were always sold at par. Although marginal debt revenues would always be the same positive value in this case—equal to the par value of the security—marginal interest outlays would increase with increased allocations to the nonbank public because of increasing nominal interest rates. As a result, at some allocation of debt, marginal interest outlays might exceed marginal debt revenues. The sale of additional nonbank debt at par would then cost more in terms of annual interest costs than such debt would bring in. This would be a similar situation to negative marginal revenues in the sale-below-par case.

do have economic effects apart from the "housekeeping" problems they entail for the Treasury. Interest costs may exert incentive and distributional effects because of the tax payments they occasion. Distributional effects should allow for the increased transfers vis-à-vis the private debt occasioned by higher levels of public interest cost. Unless given reductions in the money supply were always "worth," in terms of their economic effects, increasing increments in interest costs,[36] the optimum liquidity point would obviously not be the same point as when this is determined by consideration of the economic effects of liquidity only.

In view of these questions, rational debt management would seem to require more information than is presently available. We would have to know the various over-all relations yielded by the various alternative types of primary relations. We would have to know the economic effects of liquidity and interest costs respectively. This would involve knowing the relationship between variations in the money supply and the price level[37] and the economic effects of changes in the price level. We would also have to know the alternative distributional effects of alternative allocations of debt between the bank and nonbank public. Only when we had such knowledge would it seem possible to select that primary relation and that structure of yields that best approximated the optimum liquidity point.

The problem of policy is also complicated by questions of feasibility of schemes of direct control of monetary effects. Thus supplementary reserve schemes in conjunction with relatively liquid issues might tend to depress the over-all relations as compared with relations based on less or wholly illiquid issues without such controls. For it might then be possible to depress the primary liquidity relations by offering liquid issues at the same time that the significant moving-up effects of bank expansion were being curtailed. The optimum liquidity point would doubtlessly be quite different under these circumstances.

The need for greater knowledge about the effects of alternate policies has probably abated in recent years because of a weakening of inflationary pressures. The problems of debt management are likely to be most acute in periods of inflation. At such times, the selecting of liquidity points to the left on the liquidity map will be criticized for their over-all liquidity effects. In periods of relative stability or recession, on the other hand, low interest costs and high liquidity may both be quite desirable objectives.

[36] It is of course entirely possible that this should be so. But so far it would not seem to have been proven or disproven by empirical analysis.

[37] The short-run relationship between variations in the money supply and the price level was much debated after the postaccord experience of considerable price stability (*cf.* statement of C. R. Whittlesey, *op. cit.*, pp. 708-9; *Hearings, op. cit.*, pp. 715 ff; *Report of the Subcommittee, op cit.*, p. 19).

A GENERAL EQUILIBRIUM ANALYSIS OF EXCISE TAXES

By PAUL WELLS*

This paper will present a theory of the incidence of both the burdens and benefits an excise tax exerts in a two-person, two-factor, two-commodity, perfectly competitive world.[1] Although this attempt may appear to be unnecessarily modest, excise tax theory should be clear on this first step before additional complicating considerations are introduced to make the analysis more realistic. The main conclusions of this paper are: (a) that an excise tax exerts both a burden—an aspect of excise taxes long recognized and much discussed in the literature[2]—and a benefit, an aspect of excise taxes that has been little discussed in the literature; and (b) that these burdens and benefits fall on individuals as buyers and sellers of goods and services, and that the degree to which the burdens and benefits of an excise tax spread out from one individual or group of individuals to another individual or group of individuals will depend upon the preference functions of all individuals, the asset structure of all individuals, the tax and expenditure policy of the taxing agency, and the nature of the transformation functions of the commodities produced. We shall demonstrate these conclusions for our two-dimensional world, and then consider how far it is possible to go in generalizing from it.

* The author is a graduate student in economics at Stanford University. He is indebted to Dr. John Fei, Massachusetts Institute of Technology, and to Professor Elmer D. Fagan, Stanford University, for helpful suggestions concerning the analysis contained in this paper.

[1] Recent attempts, along much different lines from the one to be followed in this paper, to subject incidence theory to a general equilibrium analysis have been made by E. R. Rolph, "A Proposed Revision of Excise-tax Theory," *Jour. Pol. Econ*, Apr. 1952, LX, 102-17, and "A Theory of Excise Subsidies," *Am. Econ. Rev*, Sept. 1952, XLII, 515-27; R. A. Musgrave, "On Incidence," *Jour. Pol. Econ.*, Aug. 1953, LXI, 306-23, and "General Equilibrium Aspects of Incidence Theory," *Am. Econ. Rev.*, Proceedings, May 1953, XLIII, 504-17; J. A. Stockfisch, "Excise Taxes: Capitalization-Investment Aspects," *Am. Econ. Rev.*, June 1954, XLIV, 287-300. See also J. F. Due, "Toward a General Theory of Sales Tax Incidence," *Quart. Jour. Econ.*, May 1953, LXVII, 253-66.

Fagan, "Tax Shifting and the Laws of Cost," *Quart. Jour. Econ.*, Aug. 1933, XLVII, 680-710, and the literature there cited.

I. *The General Equilibrium Model*

In formulating the General equilibrium model to be used,[3] we need, in addition to the assumptions usually required by perfect competition, the following assumptions: (a) Two people, a farmer called A and and a worker, B; (b) Two factors of production: land and labor, fixed in supply and completely owned by A and B; (c) The ratio of land to labor owned by A exceeds the land-labor ratio of the economy;[4] (d) Two products: food and clothing, each of which requires the use of both land and labor for its production; (e) The production functions for food and clothing are homogeneous and of the first degree; (f) The production of food is a relatively land-intensive industry and the production of clothing a relatively labor-intensive industry.

With these assumptions, we can develop the following functions:

1. A production-possibility function between food and clothing (PP' in Figure 1).

2. A division-of-output function (KL). This function states the ratio in which output is divided between A and B for all possible output combinations to be found in PP', and can be used to show the degree to which the division of output between A and B changes as a consequence of, say, the levying of an excise tax on one of the two commodities. If we let the radial line OJ_1 be an index of output J_1, then the intersection of the KL function with this index states the ratio OD_1/D_1J_1 in which output J_1 will be divided between A and B in payment for the services of land and labor given up to the productive sector by A and B, with OD_1 of OJ_1 output going to A and the remainder, D_1J_1, going to B. From the shape of the KL function we notice that A's share of output increases, and B's decreases, as more food and less clothing are produced. This follows from assumptions (c) and (f). Assumption (f) requires the price of land to rise relative to the price of labor as more food and less clothing are produced; and, as a consequence of assumption (c), A's share of output will increase and B's decrease. The curvature of KL at, for example, any point D_1—that is, the degree to which the division of output would change as a consequence of a small change in the pattern of output from that shown by J_1—depends upon: (a) the absolute difference in the proportions in which the two factors are combined, respectively, in the two industries when the output is J_1. The greater this difference is, the greater must be the change in relative factor prices to effect a given change in output, and hence, the greater will be the change in the division of output between A, the owner mainly of land, and B, the owner mainly of labor.

[3] The model used was originally conceived of by J. Fei, and jointly developed by Fei and the author.

[4] The ratio of land to labor owned by B will necessarily fall short of the land-labor ratio of the economy.

(b) The difference in the ratio of land to labor owned by A and B. The greater is this difference, the greater will be the change in the division of output between A and B that will result from a small change in the pattern of output from J_1. The position of KL with respect to the origin depends upon the absolute amounts of land and labor owned, respectively, by A and by B. The more of both factors A owns, the farther out from O will KL be. Rather than develop the KL function rigorously—which is, at best, a tedious operation—we shall let this intuitive argument suffice.[5]
FIGURE 1

3. A specific contract curve (OF_1J_1 in Figure 1). This function is the locus of points for a particular output which satisfy the Paretian general optimum of exchange. For any possible output combination such as J_1 there is a box ONJ_1M "belonging" to that output. The dimensions of the box give the total amounts of food and clothing available for consumption by both A and B. If we place the origin of A's indifference map at O and the origin of B's map at J_1, then it is possible to define the locus of point such that it is not possible to increase the welfare of either A or B without reducing the welfare of either one or the other by a redistribution of the given output between the two. The

[5] For a somewhat different discussion of this relation, *cf.* W. F. Stolper and P. A. Samuelson, "Protection and Real Wages," *Rev. Econ. Stud.*, Nov. 1941, IX, 62-69 (also reprinted as Chapter 15 in *Readings in the Theory of International Trade*, ed. by H. S. Ellis and L. A. Metzler [Philadelphia, 1949], ff. 335-57).

locus is the Edgeworth contract curve. Since each point on PP' defines a consumption box and a specific contract curve there exists a family of specific contract curves, one for each possible output combination. An important characteristic of specific contract curves is that the slopes (marginal rates of substitution) at which the indifference curves of A's system are tangent to those of B's system are free to vary throughout the length of the specific contract curve.

4. A generalized contract curve (OF_1T). This function is the locus of points which satisfy the Paretian general optimum of both production and exchange for our model. We saw previously that for any specific output on PP' there is a locus of points associated with that output such that the marginal rate of substitution of A in consumption is equal to that of B. We shall see now that it is possible to define, for any specific output on PP', a single point on its specific contract curve such that the common marginal rate of substitution of A and B is equal to the marginal rate of transformation of that output to which the specific contract curve belongs. By finding one such point for each of a large number of specific outputs we shall have a large number of points for each of which the common marginal rate of substitution equals the marginal rate of transformation; the line traced out by these points we shall call the generalized contract curve.

To locate points on the generalized contract curve, select an output J_1 (Figure 2), and draw the box ONJ_1M belonging to that output. As before, place the origin of A's indifference map at O and let it range to the northeast. Place the origin of B's map at J_1 and let it range to the southwest. Instead of drawing in the contract curve specific to output J_1, draw in the income-consumption curve of A (OF_1GJ_1 in Figure 2) and the income-consumption curve of B (J_1F_1HO), both with reference to the price y_1. Since y_1, the relative price we take to be constant for the purpose of deriving the income-consumption curve for A and for B, is equal to the marginal rate of transformation at J_1, the income-consumption curve of A is the locus of points for which the marginal rate of substitution of A in consumption is equal to the marginal rate of transformation at J_1. The same is true for the income-consumption curve of B. At the point of intersection of these two curves (F_1 in Figure 2), the common marginal rate of substitution of A and B will be equal to the marginal rate of transformation for output J_1. Hence, F_1 is a point on the generalized contract curve, and we may say that point J_1 on the production-possibility function "contributes" point F_1 to the generalized contract curve. It may be noted that the contract curve specific to output J_1 (not shown in Figure 2) also necessarily passes through F_1.

By selecting various other points on PP' different income-consump-
FIGURE 2

tion curves for A and for B can be constructed; and their intersections will give additional points on the generalized contract curve.[6] By connecting these points we draw in OF_1T (Figure 1).

The economic significance of the generalized contract curve in conjunction with the production-possibility curve is that if competition does exist, then the general equilibrium established will yield a pair of points, one on the production-possibility curve and the other on the generalized contract curve, such that the marginal rate of transformation (opportunity costs) between food and clothing in the productive sector will be equal to the marginal rate of substitution between food and clothing for both A and B in the exchange market. This condition is represented in Figure 1 by all possible pairs of points J and F; that is, a point on the production-possibility curve and the point contributed to the generalized contract curve by this point on the production-pos-

[6] It is possible to select points on the production possibility function which "have" noninteresecting income-consumption curves Since the forces of competition would never lead the economy to such a point on PP' we can disregard these points.

On the other hand, it is entirely possible that a pair of income-consumption curves could intersect more than once. Such an *embarras de richesse* would make it very difficult actually to draw in the generalized contract curve, as has been done in Figure 1, but would in no way alter, or detract from the meaning or significance of the generalized contract curve.

sibility curve. Thus any pair of points J and F fulfills the conditions of the Paretian general optimum of production and exchange for our model.

To summarize, our model of general equilibrium contains the following elements: a production-possibility function (PP' in Figure 1); a generalized contract curve OF_1T; a family of specific contract curves of which OF_1J_1 is the contract curve specific to output J_1; a division-of-output function KL; and an index of output OJ_1. Full equilibrium in a competitive model will establish a pair of points such as J_1 and F_1. If an output J_1 is established, then opportunity cost will be c_1, with OD_1 of OJ_1 output going to A and the remainder D_1J_1 going to B in payment for the services of land and labor given up to the productive sector by A and B (Figure 1). Given their initial holdings of food and clothing, A and B will engage in trade at some price which will carry them onto the specific contract curve of output J_1. If we have, by luck, chosen the general equilibrium output, then the price established in the exchange market, y_1, will be equal to c_1, and the exchange that A and B engage in will carry them not only onto the specific contract curve at F_1, but also onto the generalized contract curve, since F_1 is the point contributed to the generalized contract curve by J_1. Full equilibrium will be established with the marginal rate of transformation (c_1) equal to the marginal rate of substitution for both A and B (y_1).

To facilitate the analysis of excise taxes, we shall make one more assumption with respect to the organization of the economy: The productive sector is assumed to be entirely separate from the exchange market and the only information the productive sector has on which to act, aside from a knowledge of production functions, is the relative prices of goods and services; that is, A and B, as exchangers, are assumed not to communicate directly with the productive sector.

II. *Price, Output, and Income Effects*

We turn now to the analysis of the effects that an excise tax on one of the two commodities will have on commodity and factor prices, the composition of output, the division of output between A and B, and the welfare of A and B. The pair of points J_1 and F_1 in Figure 3 characterize a possible competitive equilibrium position of our system in the absence of any excise taxes. Now let an excise tax of x per cent be applied to the sale of clothing. This means that the purchasers of clothing will be required to pay for it a price of $(y_1 + t_1)$, where t_1 is x per cent of y_1 while the purchasers of food will be able to exchange clothing for food at the old price of y_1 as long as output J_1 persists. The first and lasting effect of this tax is to destroy the efficiency with which output J_1 is
FIGURE 3

distributed by requiring A to pay a different price for clothing ($y_1 + t_1$) than B receives (y_1) for selling clothing to A.[7] With different prices facing our two exchangers, it is no longer possible for both A and B to equate their marginal rates of substitution between food and clothing to a single price, and hence the marginal rate of substitution between food and clothing will no longer be the same for A and for B. A second effect of the tax is to destroy the equilibrium of the system and to require a new general equilibrium to be found which is consistent with the tax on clothing.

At the new price ($y_1 + t_1$) confronting him, A would want to exchange food for clothing until he again equated his marginal rate of substitution to price. This would occur at point Q, the intersection of ($y_1 + t_1$) with A's offer curve aa', which would require A to exchange D_1V food for VQ clothing. On the other hand, since B is a seller of clothing and a buyer of untaxed food, his plans would not be affected by the tax on clothing. Price y_1 would remain the price at which he could exchange clothing for food, and point F_1 would continue to be the optimal position in consumption for B. However, since B can sell

[7] "An excise tax interferes with allocating efficiency, because it makes the relative price of the taxed commodity different for different members of the community—producers being interested in the price net of tax, and consumers in the price including tax." T. Scitovsky, "A Reconsideration of the Theory of Tariffs," *Rev. Econ. Stud.*, Summer 1942, IX, 94 (also reprinted as Chapter 16 in *Readings in the Theory of International Trade*, ed. by H. S. Ellis and L. A. Metzler [Philadelphia, 1949]).

to A only as much clothing as A is willing to purchase, B's sales of clothing would, as Figure 3 indicates, fall short of that amount necessary to allow him to reach point F_1. At the existing pair of prices, A would purchase VQ (equal to SR) clothing from B with D_1V food, D_1S of which would go to B in payment for SR clothing, with the balance SV taken by the taxing agency. Exchange between A and B to this extent only, while allowing A to locate at his optimal position in consumption, Q, would leave B located at point R, a suboptimal position with respect to price y_1, unable to engage in the further exchange which would be necessary to carry him to F_1 for want of a buyer of clothing. If, then, trade is carried on until the pair of points Q and R are reached in consumption by A and B, the existing pair of prices y_1 and $(y_1 + t_1)$ would have failed to clear the market, for B would be left with an excess supply of clothing equal to RN and an excess demand for food equal to NF_1. Since the productive sector responds to, and only to the signals of excess supply and demand, more food and less clothing will be produced, and the original pair of prices and output will not persist.

Adjustments in output will be carried out in the productive sector, which will in turn require changes in relative factor prices, until an output is arrived at in the productive sector and a pair of prices is found in the exchange market which clears the market; that is, a pair of prices which makes it possible for A to equate his marginal rate of substitution between food and clothing to the price-plus-tax, and B to equate his marginal rate of substitution to the price established, with excess supply and demand of either commodity equal to zero.[8] In Figure 4, let this pair of equilibrium prices be y_2 and $(y_2 + t_2)$, and let the output be J_2. The price of food would be higher than that shown by y_1 in Figure 3, and the price of clothing including tax would be lower than that shown by $(y_1 + t_1)$. The new output, J_2, would be made up of a higher proportion of food than in the case of J_1. The division-of-output function would tell us, if it were drawn in, that OD_2 of food and clothing would go to A and the remainder to B. A will exchange D_2V food for VQ clothing and locate at point Q in consumption. B will exchange VQ clothing for D_2S food and locate at point N in consumption. The remainder of the food, SV, will go to the taxing agency, and for the present we ignore the possible effects of the spending policy of this agency. Both A and B achieve their optimal positions in consumption,

[8] It is not within the scope of this paper to discuss the stability conditions of the model. We shall assume that positions of stable equilibrium do exist. It can be shown that stability depends on the preference functions of all individuals, the asset structure of all individuals (by this we mean the ratio in which individuals hold land and labor and not the absolute amounts held), and the production functions of all commodities. The more similar are the first two among individuals and the last among commodities, the more stable will the system likely be. It appears that similarity breeds stability.
FIGURE 4

given their "incomes" and the prices that confront them. There exists no excess supply or demand of either commodity. Hence, the triplet of points J_2, N, Q characterizes a full general equilibrium position of the model given an excise tax of x per cent on clothing.

Since the points N and Q are not on the specific contract curve of output J_2, they can hardly be on the generalized contract curve. The economic significance of this is that not only has the distributive efficiency of the system been impaired (by the dual prices), but so has the productive efficiency of the system been impaired. This is true because for at least one individual (in this case A), the marginal rate of transformation of food into clothing does not equal the marginal rate of substitution between food and clothing. The taxing agency has reduced the welfare of the community A-B in two distinct ways:[9] first, by withdrawing SV amount of food from the market; and second, by establishing a tax structure such that it is not possible to satisfy the conditions of the Paretian general optimum of production and exchange.[10]

[9] At this point we cannot say that the taxing agency has reduced the welfare of A and/or B for as yet we do not know if either A or B is worse or better off. We know that either A or B must be worse off and that perhaps they are both worse off. We shall further explore this matter shortly.

[10] The same tax SV could be collected in another way so as not to impair the productive or distributive efficiency of the system (*cf.* R. K. Davidson, "The Alleged Excess Burden of an Excise Tax in the Case of an Indiviudal Consumer," *Rev. Econ. Stud.*, 1953, XX, 209-15). We might ask at this point, why does not A escape the burden of paying an excise tax on clothing by taking his D_2V food, not to the exchange market for VQ

FIGURE 5

At first glance it looks as if the burden of the excise tax falls directly and entirely on A, the purchaser of clothing, and not at all on B, the purchaser of food. But because A "pays the tax" in the crude sense of handing over a certain amount of food to the taxing agency, this does not mean that the entire burden of the tax does fall on A, in the sense that A becomes worse off after the tax is levied, and that B's welfare is unaffected by the tax on clothing. In fact, it is possible to define situations in which A is better off as a result of the tax, and situations in which his welfare is unaffected by the tax, as well as situations in which he is made worse off by the tax.

From the shape of the KL function in Figure 5 we see that when clothing is taxed and, as a result, the output of food increases, A's share of output increases. This is because A owns a more than proportionate

clothing, but to the productive sector and transform it into VW clothing? The answer is that we assume that the productive sector responds to the signals of excess supply and demand only and not to the implorings of individuals. In the economy of the United States it is not possible for individuals to go to Durham, say, and directly transform their labor power into cigarettes to avoid paying federal, state, and local taxes. An excise tax on clothing can be collected only if clothing is purchased in the exchange market, and although A may refrain from buying clothing, he is forbidden to transform his excess supply of food into clothing in the productive sector.

share of land, the factor whose relative price increases as the output of food increases. The question now is whether A will be better or worse off after paying taxes on the clothing he purchases. It is possible to conceive of an after-tax equilibrium such that we would have an output combination J_2 (Figure 5), a pair of prices y_2 and $(y_2 + t_2)$, and a division of output D_2 which together would result in A being just as well off after the tax as before the tax, leaving the full burden of the tax to be borne by B. In this special case the benefit of an increased price for labor accruing to A would be just offset by the burden of an increased price for clothing on A. With output J_2 divided at D_2 and with a price for clothing of $(y_2 + t_2)$, where y_2 is less than y_1, but $(y_2 + t_2)$ is greater than y_1, A would exchange food for clothing up to F_2, on indifference curve I_a, the curve he was originally on at point F_1. B would exchange clothing for food at a price y_2 up to point N on indifference curve I'_b, which is lower in his preference system than is curve I_b, the curve he was originally on at point F_1. Hence, even though A pays the tax by handing over to the taxing agency F_2N food as he purchases clothing, the entire burden of the excise tax would be shifted to B if output were to change in response to the excise tax from J_1 to J_2.

For shifts of output into food greater than the shift from J_1 to J_2, A's post-tax position will actually be superior to his pretax position, and B would suffer not only the entire tax burden, but also the burden of A's enhanced income position. For shifts of less than J_2, the burden of the tax will be divided between A and B, with A bearing the entire burden in the unlikely event that there is no output shift into food. In the even more unlikely case of clothing being an inferior good to A, a tax on clothing would give rise to a greater output of clothing, and A would then bear the entire burden of the tax plus the burden of B's superior income position.

The magnitude of the output shift into food required to place the entire burden of the tax on B depends upon the rate at which A's share of output increases as more food is produced. This rate, shown by the curvature of KL, as we have seen[11] depends mainly on the following two factors: (a) The ratio in which A (and hence B) own land and labor. The greater the ratio of land to labor owned by A the greater will be A's increase in the share of output as more food is produced. (b) The difference in factor utilization between the labor-intensive clothing industry and the land-intensive food industry. When factor intensities are different a change in the composition of output will require, assuming full employment, factor-price changes in favor of the factor intensively used by the expanding industry, which in this case, is land. The

[11] *Supra*, p. 346.

greater is this difference in factor intensities, the more the price of land must rise and the price of labor fall, and the more will A benefit by a given change in the composition of output in favor of food.

The actual change in the composition of output in favor of food that does take place in any given case depends upon the following four factors:

1. The excise tax levied on clothing. The greater is the excise tax levied on clothing, the greater will be the shift into food.

2. The marginal rate of substitution for A and for B between food and clothing. The closer substitutes food and clothing are for A, the greater will be A's shift into food when clothing is taxed. For B, as more food is produced, its price in terms of clothing will increase, and the less close substitutes these two commodities are, the less rapidly will B decrease his consumption of food as its price increases.

3. The tax-expenditure policy of the taxing agency. The greater is the proportion of tax receipts "spent" on food, the greater will be the output shift into food. In the above analysis we have implicitly assumed that the taxing agency purchased no clothing from B and did purchase, in effect, only food with its tax receipts. Alternatively, the taxing agency could spend its entire tax receipts SV (Figure 3) on QU clothing by engaging in exchange with B at the untaxed price of y_1. As a result of this additional exchange B would find it possible to locate at point U in consumption and consequently his excess supply of clothing would be reduced from RN to UW and his excess demand for food reduced from NF_1 to WF_1. The increase in the output of food and the decrease in the output of clothing necessary to wipe out the existing excess supply and demand for clothing and food, to bring the system into general equilibrium, would then be smaller than before. If point U were located on top of point F_1, then the equilibrium of the system would not be disturbed by the tax, for both excess supply and demand would remain equal to zero. There would then be no change in the composition of output in response to the tax on clothing and the entire burden of the tax would fall on A, the purchaser of taxed clothing. For a more complete analysis of the equilibrium position of the system after an excise tax is applied, knowledge of a "government preference function" or a set of expenditure plans stating the proportions of food to clothing on which the taxing agency would spend its tax receipts at various levels of prices and receipts would be required.

4. The difference in the land-to-labor ratio used in the labor-intensive clothing industry and the land-intensive food industry at given factor prices. The smaller is this difference, then the closer substitutes food and clothing are for each other in production. The closer the two commodities are substitutes for each other in production, the greater will be the

output response of food to a given increase in the price of food. In geometric terms, the closer food and clothing are substitutes for each other in production, the flatter will be the curvature of PP', the production possibility curve, in the neighborhood of point J_1 (Figure 3). The more closely PP' parallels y_1 in the neighborhood of J_1, then the greater will be the increase in the output of food in response to a given increase in the price of food.

Hence, the manner in which the incidence of the burdens and benefits of an excise tax rests upon A and B depends upon the production functions of both commodities, the structure of asset holdings and the preference functions of both individuals, and the government tax and expenditure policy. This is, of course, not a surprising result, and many economists might have long suspected that a careful application of general equilibrium analysis would yield these conclusions as a matter of course.

III. *Conclusions*

It has not been possible for the author to construct an analogous model for an n-dimensional economy. However, on the basis of the preceding analysis, it does appear possible to draw a few rather weak conclusions regarding the burdens and benefits an excise tax will bring about in a more complicated economy.

In the usual case where elasticities of demand are greater than unity, total spending on the output of any given industry will decrease as that industry is taxed. The output of the taxed commodity will decrease and its price will increase. Demand for the complements of the taxed commodity will decrease and both the price and output of these commodities will fall. Resources will be released by the taxed industry and industries producing commodities complementary to the taxed commodity. Increased spending will be directed toward the output of industries producing substitutes for the taxed commodity and to the industries producing commodities complementary to the substitute commodities of the taxed commodity. Additional resources will be demanded by these expanding industries. If the economy is to respond to the change in spending with a change in the composition of output, it will be necessary for relative factor prices to change if it is the case—as a priori appears likely—that the contracting industries employ factors, and hence release them, in different proportions from those characteristic of the potentially expanding industries.[12] The relative prices of certain factors will fall, irrespective of whether they are employed by

[12] On this point, see J. Robinson, "Rising Supply Price," *Economica*, N. S., Feb. 1941, VIII, 1-8; reprinted in *Readings in Price Theory*, ed. by G. J. Stigler and K. E. Boulding (Chicago, 1952), pp. 233-41.

the contracting industries or all other industries,[13] and the owners of these factors will be, *ceteris paribus,* worse off because of the tax. The relative prices of certain other factors will rise, no matter where they are employed, and the owners of these factors will be, *ceteris paribus,* benefited because of the tax. In order to know just which factors will be made worse off and which better off, it would be necessary to know: (a) the industries away from which consumers direct their spending, and the industries toward which they direct their spending, as the output of one industry is taxed; (b) the direction of spending of the additional tax receipts by the taxing agency; and (c) the proportions in which the expanding industries and the contracting industries employ the various factors of production. The excise tax will also exert a burden on the consumers of the taxed commodity, the substitutes of the taxed commodity, and the complements of these substitutes; and the burden will be heaviest for those consumers for whom there exist few, or no close substitutes for the taxed commodity. The excise tax will benefit not only those owners of factors of which the prices have increased, but also the consumers of the complements of the taxed commodity.

Again, if we knew the preference functions and asset holdings of all individuals, the production functions of all commodities, and the tax and expenditure policy of the taxing agency, we could arrange all individuals on a "benefit-burden" scale according to how their welfare is affected by an excise tax on a particular commodity or group of commodities. The burden limit of this scale would be occupied by those individuals whose welfare would be reduced the most by the effects of the tax: those individuals who are heavy consumers of the taxed commodity, its substitutes, and the complements of its substitutes—that is, consumers who happen to have strong preferences for those commodities whose prices increase because of the tax—and who are also owners of factors which are intensively used by the contracting industries and which suffer a relative price decrease. The benefit limit of the benefit-burden scale would be occupied by those individuals whose welfare would be increased the most by the effects of the excise tax: those individuals who have strong preferences for the complements of the taxed commodity and for whom there exist many close substitutes for the taxed commodity, and who are also owners of factors intensively used by the expanding industries. The remaining individuals fall somewhere between these limits, depending on how strongly the benefit-burden forces of increased—or decreased—commodity and factor prices operate on each individual as a consumer and as a factor-owner.

Unfortunately, it appears that for the *n*-dimensional case, just as for

[13] Since factors of production are assumed to be mobile.

the two-dimensional case, more knowledge is necessary than is available to place individuals on such a benefit-burden scale. Even worse, one crude inference which it was possible to make in the two-dimensional case cannot be made for the *n*-dimensional case. We know that with only a labor-intensive clothing industry and a land-intensive food industry, a tax on clothing will, *ceteris paribus,* make owners of land better off because the price of land would increase relative to the price of labor. However, in the *n*-dimensional case, it is not possible to know beforehand, in the absence of complete information, which factors will benefit from a shift in demand, simply because it will not be known to which industries spending will be transferred.

Our knowledge of incidence for any "real" economy now appears to very slight indeed. We do know, however, that excise taxes exert benefits as well as burdens on individuals; and we are also aware of the main factors involved in the spread of the benefits and burdens of an excise tax in a competitive economy. The foregoing observations further suggest that more specific results concerning the incidence of excise taxes can be obtained for those cases in which additional appropriate assumptions regarding the shapes of the relevant parameters (preference functions, production functions, relative size of industry taxed, etc.) can be made in such a way as to eliminate the general equilibrium consequences of these taxes and confine their effects to definite individuals, or groups of individuals, in the economy. For example, the long-established theorem of partial equilibrium analysis that the burden of an excise tax on a particular commodity will be divided among the consumers and producers of the taxed commodity according to the elasticities of supply and demand requires only the additional assumption that the taxed industry is so small that the prices of all *other* commodities and the prices of *all* factors do not change.[14]

POST-KEYNESIAN ECONOMICS[1]

A Review Article

By ALVIN H. HANSEN*

This is a collection of essays by fifteen authors whose names are for the most part well known. The book is divided into three sections, the first of which relates to monetary theory and policy; the second, to economic fluctuations and growth; and the third, to aggregative economics and testing. On a somewhat different basis of classification, three chapters are empirical in character, two compare current economic thinking with earlier doctrines (Marx and the classicals), five are concerned with monetary theory and policy, four with cycle policy (investment control, depreciation policy, income distribution, institutional change), and one with nonlinear cycle theories. While Part III is much the best, some of the chapters in the first two parts make rewarding reading. And though my review is essentially critical, I feel that the book is decidedly worth while.

Does the volume live up to its title *Post-Keynesian Economics?* Yes and no. It is post-Keynesian in the sense that most of the discussion is cast in terms of the Keynesian tools of analysis. It is post-Keynesian in that the endeavor is made here and there to improve on Keynes, but the result in this respect is far from impressive. It is post-Keynesian in the sense that a part of the volume is devoted to "filling the empty boxes" of the Keynesian analysis with empirical data. Especially notable here is Klein's chapter—an outstanding contribution—and those by Tarshis and Modigliani. It is post-Keynesian in the respect that it seeks in two chapters (Tsuru and Streeten) to assess the Keynesian stream of thinking against the background of earlier traditions. It is post-Keynesian in the respect that it takes a fresh look in a number of chapters at policy programs stemming from the Keynesian system.[2]

On balance the gleanings must be set down as relatively meager, though the volume does contain, as indicated above, a number of notable chapters. That the gleanings are somewhat meager both with respect to tools of analysis and policy matters, after nearly twenty years of voluminous discussion, makes Keynes' individual work stand out all the more strikingly as a truly Herculean contribution to modern economics.

* The author is Lucius N. Littauer Professor of Political Economy, Harvard University, Cambridge.

[1] K. K. Kurihara, editor, *Post-Keynesian Economics* (New Brunswick: Rutgers Univ. Press. 1954. Pp. xviii, 442. $8.50).

[2] The title *Post-Keynesian Economics* might, however, lead the reader to think that the volume perhaps attempts a survey of the literature which has appeared since 1936. This is not the case. Current literature is of course touched upon here and there but only in a casual manner.

First let us consider the empirical studies. Keynes' system is built on the foundation of several specific hypotheses concerning human behavior. Does empirical investigation support or contradict this foundation? This is the question to which Klein addresses himself. He notes that the essence of Keynesian economics can be stated as follows: "The system of classical competitive equilibrium does not automatically lead to a stable solution of full employment" (p. 281).

The only empirical findings to date, says Klein, that are in any way contrary to the essence of Keynesian economics are the data on the influence of liquid wealth on saving—the so-called Pigou effect. But the empirical evidence is not clear-cut against the Keynesian theory, the evidence being mixed in direction of effect. At all events, the magnitude of the "marginal asset effect on saving is probably not large enough to render market forces adequate operators of adjustment towards full employment equilibrium" (p. 294).[8]

Klein's chapter, which no economist can afford to neglect, is remarkable for the vast range of empirical materials, covering all aspects of the Keynesian analysis, which are surveyed. He concludes that the Keynesian system is "firmly rooted in fact" and that any reader, whether convinced or not, must at any rate agree that the empirical evidence is not superficial or casual.

Tarshis has given us, in his essay on "The Flow of Business Funds, Consumption and Investment," a welcome contribution. Keynes put forward the proposition that consumption is a function of *national* income. Much of the literature, however, has restricted itself to the relation of consumption to disposable income—a much narrower concept. When consideration is given to the multiplier effect of an increase in investment or a reduction in the taxes on consumers, it is the marginal propensity to consume out of an increment of *national* income that is relevant. The bites taken by the progressive rise in business saving and by a progressive tax system (individual and corporate combined) are far more important than the saving of individuals in determining the slope of the consumption function and so the multiplier. We have had too little empirical investigation of the "tax bite" and of the "business savings bite." Keynes, as Tarshis reminds us, had much to say about the important role of dividend policy and depreciation policy in establishing the relation between income and consumption.

The gross national product is equal to consumption plus individual saving plus gross business saving plus *net* taxes. By "net taxes" I mean total tax receipts minus transfer payments. Tarshis calls this "government saving," but this seems to me an unfortunate term. He presents tables for these three categories from 1929 to the present, showing their relative importance in holding consumption below the GNP. Personal saving throughout the period has played a relatively small role.

[8] Referring to two recent studies of the consumption function (Ruth Mack's in *A Survey of Contemporary Economics*, Vol. II [Homewood, Ill., 1952], and R. Ferber's *A Study of Aggregate Consumption Functions*, Nat. Bur. Econ. Research Tech. paper [New York, 1953]), Klein concludes that neither of these studies is sufficiently discriminating in its choice of empirical studies since they "draw upon results that are open to serious criticism from an econometric point of view" (pp. 294-95).

Tarshis also examines the impact of business saving on investment (pp. 381-86) and the role of *sources* of funds (retained earnings, stock issues, borrowing) on decisions to invest. Keynes undoubtedly did not pay adequate attention to the availability of internal corporate funds and their impact on investment decisions.

The third empirical essay is the chapter on "Utility Analysis and the Consumption Function" by Modigliani and Brumberg. What is the impact of long-range plans and expectations on consumption expenditures? Current income, expected future income, initial assets, and age, are among the more significant factors. Since it is not possible to obtain the relevant data from the observation of individuals over time, the authors content themselves with "cross-section" data on the average and marginal rates of consumption with respect to household incomes.

From their so-called "stationary" cross-section data, they conclude that (despite appearances to the contrary) the *proportion* of income saved is in reality independent of the household income bracket, but tends to rise with age. The regression of consumption on income *tends* to be linear and a line fitted to the data tends to go through the origin. But a household whose income *unexpectedly* rises will save more than the normal ratio.

These propositions are certainly rather novel. Margaret Reid had, however, already suggested that there is "good reason to believe the percentage of income saved to be independent of the economic level of the separate families."[4] Earlier writers (Brady and Friedman) have found from family budget studies that the *ratio* of saving to income *is* a function of the family's position on the Lorenz income distribution curve—a proposition contrary to the one stated above. Nevertheless the ratio of aggregate saving to aggregate family income *over time* is not thought to be a function of income.[5] This however does not tell us what is the relation of consumption to *national* income either in the business cycle short run[6] or over the longer run.

Now Modigliani and Brumberg agree indeed that the data do show that the *ratio* of saving to income is a function of the income bracket in which a household's income falls, but they hold that the higher *ratio* of saving to income in the upper brackets is not due to the fact that they are upper-bracket incomes. Rather, this rising ratio is due to the fact that households in these upper brackets are, by and large, "recent arrivals." Their current incomes are above their *accustomed* incomes, and therefore they tend to save a higher ratio of income. If the new income is regarded as *transitory* the saving ratio will rise. Or, in the event that the new income is regarded as permanent, the initial asset holdings are now out of line with the revised outlook. Thus the saving ratio must rise in order to bring the asset holdings up

[4] See *Savings in the Modern Economy*, ed. by Heller et al. (Minneapolis, 1953), p. 219.

[5] See also James Duesenberry, *Income, Saving, and the Theory of Consumer Behavior* (Cambridge, Mass., 1949).

[6] Modigliani and Brumberg's chapter relates to budget studies and not to the behavior of consumption in relation to national income over the cycle. Thus their attack (p. 43) on those who have employed the Keynesian consumption function is not valid. The secular aspect of the matter is something else again. See in this connection my *Guide to Keynes*

to a level commensurate with the new income.[7] But if all incomes were at their accustomed levels, the ratio of saving to income would, they believe, be quite unaffected by the level of the household's income. In the absence of unexpectedly large incomes, the authors suggest that households save primarily to cushion against major variations in income over the life cycle, and that the savings which a household wishes to make and can afford to make must be basically *proportional* to its basic earning capacity.

This conclusion is admittedly a tentative one and the authors wisely refrain from dogmatism. Whether right or wrong, is the hypothesis at variance with Keynes' formulations with respect to the relation of consumption to income? In answer to this question the authors are, to put it mildly, a bit irresponsible. They fail to point out that their conclusion does not in the least contradict Keynes' statement that we can take it as a "fundamental psychological rule of any modern community[8] that, when its real income is increased, it will not increase its consumption by an equal *absolute* amount" (*General Theory*, p. 97). Instead they claim that they depart from Keynes. But their citation from Keynes consists of a casual side remark and not from his central argument. Moreover the citation significantly omits the phrase "as a rule" which, if included, would have shown that Keynes made no firm "contention" about the *proportion* of income saved as income rises.[9] Finally, and this is highly important, Keynes was talking about the behavior of the "modern community" as a whole, including business saving as well as individual saving. Thus Modigliani and Brumberg are not even talking about the same thing as Keynes! And even though they were, it is not true that their findings (if verified) would show Keynes to be in error.

Tsuru is concerned with the history of economic ideas with special reference to Keynes and Marx. The appearance of the *General Theory* caused at first a sharp division among the ranks of economists between those who emphasize the income effect and those who emphasize the "efficacy of cost-price relation-

---

(New York, 1953), pp. 75-78; also my *Business Cycles and National Income* (New York, 1951), pp. 164-70.

Moreover, the proposition that the *ratio* of saving to income is independent of income is often misinterpreted to mean that *saving* is not a function of income. This misconception has led to a vast amount of confusion, and to quite unfounded charges that Keynes' position has been proven to be in error.

[7] This lag effect is emphasized by Keynes on p. 97 of the *General Theory* where he discusses the difference between one's "actual income" and one's "habitual standard." But is this sufficient to explain the higher saving ratio in the upper income brackets? Is it not also true, as Keynes put it (p. 97), that the "motives towards accumulation" only acquire effective sway "when the margin of comfort has been attained"?

[8] Note that Keynes speaks of the modern *community*, and that his elaborate discussion of the psychological behavior pattern of the community involves not only the behavior of individuals as consumers, but also as government officials managing sinking-funds, and business officials managing depreciation funds, etc. The current literature is full of misinterpretations of Keynes' "psychological law."

[9] Indeed in the very next sentence, following the phrase which our authors quote, Keynes explicitly disavows any firm contention, for he says: "But whether or not a greater proportion is saved, we take it as a fundamental psychological rule . . . etc." (The completed sentence is given above.)

ships." This division has gradually given way to "an attempt at synthesis." Marx, while recognizing the effectiveness of price adjustments, developed his theory largely in terms of "long-run normal price." "In other words, 'parametric adjustments' have no place in the stage of abstraction where Marx took up his aggregative analysis" (p. 333). Tsuru attempts to contrast the Keynesian aggregates and the Marxian aggregates in economic analysis. This effort necessarily requires a good deal of reading between the lines.

Streeten's excellent chapter is on "Keynes and the Classical Tradition." Attention is centered around the "harmony of interest" doctrine. "Keynesian theory strengthened the utilitarian tradition because it resolved one of the great moral dilemmas of the neo-utilitarians" (p. 351). A more egalitarian income distribution might raise general welfare, but inequality appeared to be necessary to safeguard adequate savings and so investment. Thus greater equality might defeat, as the utilitarians saw it, its own purpose. But Keynes' consumption function analysis showed that a decrease in thrift might in fact raise income and investment, and so there might well be no conflict.

While Keynes believed in the virtues of the free market and the pricing system, Streeten continues, his measures for regulating investment represent a break with liberal-utilitarian tradition. Moreover, he did not believe, as did Mill, that production would "look after itself." Here he was more like List than the classicals. Keynes thought that the state must take certain actions "in order to create the right environment for private self-interest to work."

Keynesian policies are designed to promote employment and prosperity—the "interests of all." Then why is there opposition to Keynesian policies? There are various reasons, *e.g.*, they may undermine the discipline of workers, entrepreneurs may fear that their power and status in society will be reduced, etc.

Streeten suggests that Keynes believed more strongly in a "harmony of interests" than recent full-employment experience would warrant. Here he calls attention to the oft expressed fear that full employment and price stability are incompatible. (Streeten, however, fails to canvass adequately American experience since 1948.) Reference is also made to the conflict that may arise between full-employment and balance-of-payments problems.

Under large-scale unemployment, one group's gain need not spell another's loss. But with full employment, conflicts over the "full-employment pie" emerge.

In the Victorian society, convention and superstition tended to prevent an open conflict of interest. The gold standard, the balanced budget, the acceptance of unemployment, etc., testify to the "submission to external unquestioned rules and conventions" (p. 362). But this quasiharmony broke down because the loss of these ancient beliefs "stripped the structure of economic relations of the superstitions which had cemented them." Keynesian economics helped to destroy the "barriers which prevented the full pursuit of a selfish manipulation of society," and thus brought "clashes into the open" (p. 362).

Yet Keynes' thought is "unmistakably in the classical liberal-utilitarian

tradition." He advocated the "regulation of *aggregates* only." Nevertheless, in a country pledged to full employment, the classical conflict of interests has again more or less come into its own, and in addition new problems have arisen.

A number of chapters deal with the business cycle, partly in terms of theory but more often in terms of policy. Matthews' paper is on "Capital Stock Adjustment Theories" and the problem of stabilizing investment at a level "such as not to cause the stock of capital to increase so rapidly that a decline in its marginal efficiency occurs" (p. 173). The boom level of investment is not maintainable for reasons made plain by the capital stock adjustment theories. "The dilemma is, then, that a rate of investment high enough to give full employment leads to excessive capital accumulation and is not maintainable" (p. 173). Investment must therefore be stabilized at lower than the boom level and this would require for full employment a rise in the consumption function; or alternatively there might be offsetting increases in government spending.

Matthews poses this problem in relation to three theories of the cycle: (1) Schumpeter's innovatory investment theory, (2) the Wicksell-Frisch theory of damped cycles sustained by erratic shocks, and (3) the theory of antidamped cycles whose explosive tendencies are contained by various restraints (Hicks, Goodwin). It is the "ceiling theory" to which Matthews devotes primary attention. The ceiling may be imposed by a general shortage of factors or by bottlenecks in the investment industries—the "investment ceiling." In place of the ceiling hypothesis, we have Keynes' view that full employment of factors is likely to "transform a boom into a cumulative inflation of wages and prices" (p. 180). This Matthews calls "Wicksellian instability."

Matthews closes his theoretical analysis with the conclusion that if the Hicks-Goodwin theory can be at all accepted as realistic (a point left unsettled) then cyclical instability must probably be faced and in addition there is the danger of "Wicksellian instability." Thus the authorities are confronted with the policy alternatives already referred to above. Of these alternatives, Matthews favors a policy of direct control of investment. This policy, he believes, is likely to be effective in a condition of overexpansion such as most countries have had to contend with during the last ten years owing to war-created shortages, and more recently to rearmament expenditures. "But we must not shirk contemplation of the time when this will not be so" (p. 191). Unfortunately, however, the essay throws no new light on how we should solve this problem if and when more normal conditions arrive. Thus this very useful essay is more interesting in its theoretical implications than as a guide to policy.

Ichimura's chapter, largely mathematical, is devoted to a survey and comparison of recent cycle theories. He disregards exogenous theories of the Schumpeter or Spiethoff variations, and rules out endogenous linear theories as unsatisfactory, though he grants that when combined with erratic or quasi-oscillatory shocks, such systems have much to commend them. He devotes his chapter, however, to the nonlinear theory of Kaldor and those of the

Hicks-Goodwin type. He begins his essay with an analysis and reformulation of the Kaldor model, and then moves on to a comparison with other recent theories, at the same time throwing light here and there upon the relation of these to earlier theories.

The essay by Bowen and Meier is instructive and challenging. The last twenty years teach us, they think, that "painful changes in deeply-rooted institutions are involved in any effort to achieve stability via fiscal policy" (p. 164). They conclude that "stabilization necessarily involves change in firmly established institutions and is therefore likely to be difficult of attainment" (p. 168). The most difficult obstacles are: (1) the institution of budget-balancing, (2) the ponderous legislation procedures with respect to fiscal policy, (3) intergovernmental relations in a federal system, (4) the traditionally established dichotomy between state and private industry, and (5) the effort of trade unions to raise money wages.

These obstacles form well-established and persistent institutional patterns. It is a delusion, the authors assert, to suppose "that fiscal policy does not require major institutional changes" (p. 165). Fiscal policy of a magnitude to overcome a deep depression "would even today be confronted with strong institutional resistance" (p. 166).

To facilitate a stabilization program they suggest (among other things) a closer coordination of investment and saving involving control over saving or investment, or both. This might involve direct investment by the government and greater equality in income distribution.

The authors agree that a substantial residue of institutional changes bearing on stabilization was left by the social crisis created by the Great Depression—social security, financial reform, a more progressive tax structure, etc. And they agree that the resistance to change may have been "softened up a little by the arguments of economists" (p. 168). But they fear that institutional barriers may before long be "back at par."

Kurihara's chapter is basically a policy chapter, and the program he proposes, to secure full employment and growth, is primarily to raise the consumption function through a redistribution of income. The main defect in the chapter, as I see it, is that his policy directive takes little or no cognizance of social priorities. It may well be that in the visible future what is most urgently needed is public investment expenditures, not only on resource development, roads, etc., but also outlays on health, education, recreation, control of juvenile delinquency, etc., instead of more private consumption via redistribution of income. Greater equality of income up to a point is no doubt desirable, but there may be danger in pushing it so far that the strength of a vigorous middle class—upon which a dynamic society must heavily lean—may be sapped. Over against income redistribution, public investment and deficit financing are important alternative fiscal routes to full employment. The appropriate combination of all possible alternatives requires a careful assessment of social priorities. It is on this basis that we must decide how large the government budget should be, whether it is to be financed by borrowing or by taxes, and if by taxes, what degree of progressivity should be imposed. These matters are somewhat neglected by Kirihara

who concentrates his analysis on (1) raising consumption, and thereby (via the acceleration principle) stimulating private investment, and (2) lowering the rate of interest so as to push private investment toward the point of zero marginal efficiency.

Murad's chapter on "Net Investment and Industrial Progress" presents the thoroughly unorthodox view (with respect not only to classical but also to Keynesian theory) that industrial progress *necessarily* tends toward zero net investment. He begins with the well-accepted thesis that increasing capital accumulation, in the absence of growth of population and changes in technique, will reduce the marginal efficiency of capital eventually to zero. Later he introduces technical change, but argues that if technological advances occur at the same rate in producers' goods industries as in consumers' goods industries, no new opportunities for *net* investment will result from such advances.

Appraisal of Murad's argument necessarily involves consideration of what constitutes true replacement and what constitutes true net investment. To this there is no easy answer. Depreciation funds are not used, in a technologically progressive society, to replace the same old-type industrial machines. They are used to buy new and better machines. If now the depreciation sums set aside for replacement are just sufficient to buy new machines capable of producing the *same* output as the old, and if sums so spent accurately measure *replacement* investment, then (contrary to Murad's view) progress will not rule out net investment. Output all around will have increased, let us say, by 100 per cent; money wages (and other money incomes) will also have increased by 100 per cent while prices of both producers' goods and consumers' goods have remained constant. It now requires only half as many laborers to produce the new machines needed to replace the productive capacity of the old machines. Since wages have doubled, the money cost of these new machines is, however, the same as the cost of the old; therefore, if depreciation has been calculated on a money-cost basis, the depreciation sums set aside will be just sufficient to replace the old machines with machines of equal productive capacity. But half of the labor force has been set free. Hence, concomitant with the advance in technology, *net* investment is continuously necessary to provide the displaced laborers with capital equipment and to implement in terms of increasing output, the fruits of technical advance. Thus on the conditions here stated—and they do not violate his assumptions—Murad's proposition is in error.

Murad himself inadvertently admits this point without seeing how damaging it is to his thesis. He notes (footnote, p. 246) Domar's definition of depreciation as the "cost of replacement of the depreciated asset by another one of *equal* productive capacity." Murad objects to this definition on two grounds: (1) that it is not in accordance with accounting practice, and (2) that such a definition would equate all additions to capital (measured in terms of productive capacity) with net investment. The answer to these objections is first, that accounting practice (depreciation calculated on a money-cost basis) would in fact replace equal productive capacity on the assumptions which I have made above; and, second, that Domar's depreciation

does provide the best answer to the difficult question—what indeed is meant by *net* investment.

Now it was already recognized by J. S. Mill (and I have myself frequently stressed this point[10]) that a society which already has a huge stock of capital *may* enjoy increasing productivity without net investment. This conclusion rests, however, on grounds other than those laid down by Murad. It rests basically on two assumptions—assumptions which are probable, or at least possible, but which are not necessarily concomitant with a large accumulated capital stock. These assumptions are primarily: (1) that, in a modern advanced society, technology in fact has tended to produce capital-saving machines[11] (*i.e.*, technical progress in the producers' goods industries tends to exceed that in consumers' goods industries—*e.g.*, services, etc.) and (2) that accounting practice in fact tends to supply depreciation funds in excess of the amount required to maintain the same productive capacity.[12]

Finally we come to chapters dealing with monetary theory and monetary policy. I am not at all happy about any of these chapters, and I fear that my comments may be overly critical. Dillard's chapter on "The Theory of a Monetary Economy" begins with high promise but fades away at the end, it seems to me, into mysticism. Dillard tries to make something quite special out of Keynes' "Essential Properties of Interest and Money" but fails, I think, to add anything to Lerner's important article.[13] While much of the chapter is well written and thought-provoking, its central thesis does not, in my opinion, stand up well.[14] He attempts to show that in Keynes' theory

[10] In my *Fiscal Policy and Business Cycles* (New York, 1941), I canvassed this matter with some care (see pp. 310-11). Among other things, I stated: "A mature economy may, as Mill stated, under certain conditions modernize and improve its capital equipment, introducing continually new techniques, without tapping any new savings or making any net addition to capital formation. If the progress of technique in the capital goods industries outruns the rise in wage rates, then the accumulated depreciation reserves will be adequate to finance the replacement of an old machine by a new one more productive than the old." Also the following: "When capital saving innovations are made . . . the expenditure of replacement allowances will yield a net increase in productivity."

[11] Murad indeed discusses capital-saving inventions (p. 244), but he does not succeed in clarifying the issue. The definitions which he presents on page 245 are vague and confusing.

[12] See in this connection my "Growth or Stagnation in the American Economy," *Rev. Econ Stat*, Nov. 1954, XXXVI, 409-14

[13] See also my chapter on "Nature and Properties of Capital, Interest, and Money" in my *Guide to Keynes, op. cit*

[14] Dillard attempts to elevate the highly perfunctory chapter which Keynes wrote for the Spiethoff *Festschrift* (Munich, 1933) into a monumental contribution He asserts that this chapter appears to be unknown to English-speaking economists, probably because it appeared in a German volume But Keynes' chapter is in English (other English chapters are by Robertson, Mitchell, Carl Snyder, and Hawtrey), and the volume has frequently been cited by English and American writers on business cycles. In my own case, I have used the volume a good deal and have been familiar with the Keynes chapter from the time it appeared. But I have always regarded it, and still do, as a slight piece, probably dashed off in an hour or two and neither a credit to Keynes nor to Spiethoff in whose honor it was written. As one rereads it, it becomes quite clear that all sorts of things which later were spelled out clearly in the *General Theory* (not simply a *monetary* theory) were floating around in his mind. About the only interesting thing in the essay is the announcement (1933) that he was working on an important new book.

"money holds the key to explaining unemployment" (p. 20); again that "the ultimate theoretical explanation of unemployment must be sought in money" (p. 22); or again, that money is "the strategic factor" upon which Keynes' entire analysis focuses (pp. 19-20). This of course is not the first attempt to show that the whole Keynesian system rests on a single pivot.

Dillard is in fact less one-sided than some of his more extreme statements would indicate. The chapter, however, ends somewhat disappointingly as one encounters repetitions of such phrases as "the monetary theory of employment," "the nature of money as the key institution of modern capitalism," money's "role as a special form of property," etc.

Martin Bronfenbrenner believes that events thus far indicate that, for causes quite apart from war and rearmament,[15] we are now in a new phase of secular inflation owing to "pressure economics" and "Keynesian economics" (p. 39). These new developments certainly raise important issues which deserve careful study. But there is some danger in exaggerating current inflationary forces compared with those of earlier periods. Actually, the first quarter of our century was considerably more inflationary than the second quarter.[16] Or again, wholesale and consumer prices combined (prior to 1913, wholesale prices) rose 143 per cent from 1894-97 to 1923-25, but only 100 per cent from 1931-34 to 1948-50. From 1948 to 1955 wholesale prices have risen less than 1 per cent per annum, whereas from 1897 to 1910 they rose nearly 4 per cent per annum. Where were "pressure" and "Keynesian economics" then? Do these figures show as Bronfenbrenner asserts, that the strongest, most aggressive, and best-disciplined of the pressure groups were held in check, in the pre-Keynesian days, by "limitations of demand" (p. 40)?

Bronfenbrenner suggests that the inflationary movement did not subside during the relative peace years preceding Korea (p. 38). But the facts are otherwise. At the outbreak of Korea, prices stood at 157 compared with 165 for 1948. It is not true that "no substantial reversal of the inflationary trend" occurred in 1951 (p. 39). Wholesale prices turned down in February 1951, falling fairly steadily from 114.8 (new index) to 109.5 at the end of 1954.

It thus appears that it is perhaps too early to get overly alarmed about pressure groups and Keynesian economics. Indeed it may be altogether possible (though I would not venture an opinion) that collective bargaining (stable contracts over a considerable period, etc.) and the increasing spread of Keynesian economics—even involving members of Congress (witness the growing awareness of the impact of tax changes on inflation and deflation)—may give us greater price stability than was achieved over considerable periods in the "good old days."

With respect to the future, however, Bronfenbrenner has no illusions that the old methods could any longer be effective to hold down inflation. Labor

[15] Bronfenbrenner asserts that it is a "convenient escape . . . to ascribe the inflation completely to the military factors of war and rearmament" (p. 38).

[16] From 1900 to 1925, wholesale prices and consumer prices (wholesale prices alone prior to 1913) rose by 103 per cent; from 1925 to 1950 these price indexes rose by only 40 per cent.

will no longer tolerate either mass unemployment or gross inequality in income distribution—both powerful deflationary forces. He pictures labor as currently trying the inflation route to full employment and greater equality. But labor will, he thinks, eventually realize the futility of inflation. The drive toward greater equality will however continue and this may tend to dampen growth and efficiency.

Perhaps, but no such tendencies are currently visible. Bronfenbrenner does not adequately appraise the contribution to efficiency and stability of greatly improved labor-management relations—a development which has taken place during the last twenty years of so-called "pressure economics" and "Keynesian economics."

Turning to Mabel Timlin's paper on "Monetary Stabilization Policies and Keynesian Theory," the reader will note her failure to assess the *real* factors. This is all the more remarkable since her chapter begins with a reference to Section VI of Chapter 21 in the *General Theory* which stresses the complexity of causes underlying price movements, and especially the real factors.

Miss Timlin is quite prepared to argue that during the immediate postwar years (p. 65) the rate of investment should have been restricted despite the vast backlog of urgent needs for additional plant, equipment, and housing. But would a drastic monetary restraint on investment at that time have been desirable? Dennis Robertson years ago reminded us that there are times when price stability is not necessarily to be preferred to other goals. These other goals may not be wholly realizable if price stability is rigidly pursued. Miss Timlin's paper does not realistically examine the painful choices that confronted Canada, no less than the United States, in the years that followed a *total* war in which nearly half of the nation's resources had for years been devoted to military pursuits. Could the interest-rate policy advocated by Miss Timlin have prevented price-level increases without any sacrifice of output and employment goals? And we should certainly have expected from a Canadian a full discussion of the consequences of a Canadian price policy completely at variance with American developments.

The Canadian policy-makers are roundly criticized for their expectation that the postwar inflationary situation might prove to be temporary, and that later on the problem might well be one of inadequate demand in relation to production capacity (pp. 62, 64). But what is the evidence (assuming a peaceful world) that they were not right? The inflation ran out by 1948, and since then a falling price trend has been interrupted only by the eight months of panic buying following the outbreak of war in Korea. They could scarcely be expected to know that we were soon to move into a costly cold-war situation.

Miss Timlin stresses "adequate control over the quantity of currency and bank deposits, exercised through flexibility of yields on the securities entering into the portfolios of central banks" (p. 86). She is unhappy over the reliance placed by the Canadian government on (a) its budgetary surpluses,[17] (b)

[17] Actually the cash budgetary surplus was enormous in fiscal 1947, and substantial in 1948-50. Miss Timlin surely underestimates their role in checking the 1946-47 inflation.

"suggestions" to the chartered banks, (c) consumer credit regulations, and (d) deferred depreciation tax allowances. She would like to have jumped the yields in a "*sharp and sudden and once-for-all* rise" (p. 64) but she thinks that a lagging and niggardly rise in rates, taking place by small degrees (the policy advocated by the New York Federal Reserve Bank), might aggravate the problem. She does not explain how anyone would know exactly how much that sudden sharp rise should be, or what might be the consequences of a drastic fall in capital values generally.

The *minimum* objective, she thinks, should be to prevent any increase of currency and bank deposits and to deter any flow of securities to the central bank. Actually both of these minimum objectives were achieved in the United States, but this did not prevent the price rise in 1946-47. (Currency and demand deposits stood at $106 billion in June, 1946, and at $108 billion in June, 1948,[18] while U. S. securities holdings by the Federal Reserve Banks were $23.8 billion in June, 1946, and $21.4 billion in June, 1948.)

Unlike Miss Timlin who assumes price stability as a *summum bonum*, Vickrey poses the question whether "an economy in which prices are rising steadily" may not be more stable than one with a stable price index (p. 89). He posits a "condition of specified, controlled, and generally anticipated inflation as a respectable and possibly even desirable condition" (p. 90).

The key condition, he thinks, is that inflation be generally anticipated. And it is not difficult, he says, to construct models in which *anticipated* inflation does not of itself produce instability. "Models," perhaps, yes. But what of the actual world?

Varying combinations of interest rates, tax rates, and government spending rates may of course be employed to achieve (in model building at least) any desired trend of prices. On balance, Vickery prefers a high rather than a low money rate since he prefers to operate on a liquidity preference curve that is more nearly vertical.

Vickrey guides the reader through several models, but for the most part he is aware that they have little significance for the real world, however interesting the speculations may be. Among the unrealistic assumptions introduced are the following: (1) real aspects of the economy are unaffected by monetary vagaries and are also fully anticipated; (2) public confidence in the maintenance of a precisely *steady* rate of inflation, say 10 per cent per year[19] (pp. 110, 112, 118).

Currently "wartime destruction and the demands of rearmament" have pushed the productivity of capital up into a range which gives, he thinks, sufficient margin for the effective operation of monetary controls (p. 122). But he concludes that the "long-term trend seems still to be one in which the accumulation of capital, combined with the shift towards capital-saving

[18] In Canada currency and active deficits increased by 10 per cent from 1946 to 1948.

[19] No government can be certain of continuous *full* employment, however much it may aim to achieve this goal. But is it not still more difficult to guarantee exact price stability, let alone an exact percentage *increase* in prices? Vickrey has surely not overstated his case when he says that it "may be some time before any such controlled inflation is adopted in any country as a deliberate and explicit policy" (p. 122).

innovations," will tend to drive down the real marginal productivity of capital (p. 122).

Patinkin's paper on the quantity theory is, I feel, only of limited interest. The quantity theory, given certain rigid conditions, is held to be correct. Now Keynes always held that classical theory came into its own under full-employment conditions. He laid down two assumptions under which the quantity theory was valid: (1) full employment, and (2) effective demand will change in the same proportion as the quantity of money. This latter condition would be true under *one* of two assumptions: (1) the propensity to hoard is zero; or (2), if not zero, then the liquidity preference schedule, the investment demand schedule and the consumption function are assumed to have such slopes that the aggregate demand will increase in the same proportion as the increase in the quantity of money.

Patinkin, however, argues that two conditions, and only two, are necessary to make the quantity theory valid: (1) full employment, and (2) absence of "money illusion."[20]

Patinkin thinks that his position presents a significant difference between himself and Keynes, but I question that this can be maintained. He admits that Keynes was quite right in insisting that the validity of the quantity theory was connected with the condition that effective demand must increase in the same proportion as the quantity of money. As Patinkin puts it, this latter condition is indeed a necessary consequence of his own crucial assumption with respect to the absence of any money illusion.

Patinkin's chapter, as with everything he writes, deserves the careful attention of economists, and it is possible that I have not done him full justice. At any rate this chapter interests me far less than his earlier very able contributions. With respect to this chapter, and indeed all the others as well, it is far more difficult to assess in a balanced way a book containing chapters by fifteen authors than a book of fifteen chapters by one author. All in all the book is an interesting and useful contribution to post-Keynesian economics.

[20] True, he takes cognizance (as did also the classicals) of the special condition that there must be no distributional effects such as might account for forced saving

COMMUNICATIONS

Elasticities, Cross-Elasticities, and Market Relationships: Comment

Over recent years, a good deal of confusion and inconsistency has grown up around the concept of cross-elasticity of demand, a fact which must have occasioned distress to all those who have attempted to follow the literature of value theory during this period. We are, therefore, all indebted to R. L. Bishop for his valuable and timely article on the subject.[1] In particular, Bishop has rendered us two important services. Firstly, he has provided an admirable survey of the variety of opinion surrounding the concept of cross-elasticity of demand, and has brought into the open the deep cleavages which exist. Secondly, he has recalled our attention to the fundamental fact that "the concepts in question are elasticities and cross-elasticities of *demand*."[2] In this connection, he shows how many writers have attempted to qualify the concept of cross-elasticity by reference to supply factors and directs our attention to "the profound anomalies that are implied by their half-breed supply-demand elasticities."[3] Unfortunately, however, when Bishop embarks upon positive prescription, we find that the basic confusion remains embedded in his own work.

Clearly, if we are to use cross-elasticities to define market relationships, it is essential that we have a clear conception of what they do in fact measure. Otherwise, any superstructure of market classification based upon them will be erected on shifting sands. Therefore, in this note, we shall confine ourselves to the fundamental question: What does cross-elasticity of demand measure?

The concept of cross-elasticity of demand with which we shall be concerned is that of its original sense: the ratio of the percentage loss of output by any firm j to the initiating percentage *reduction* in price by another firm i, all other prices being assumed unchanged; so that $E_{ji} = p_i \partial q_j / q_j \partial p_i$, where p_i is the price of firm i and q_j is the output of firm j, and where ∂p_i is considered in the negative sense.[4] This cross-elasticity is, then, the same as Triffin's first (sub-

[2] *Ibid.*, p. 781. Bishop's italics.

[3] *Loc. cit.*

[4] Strictly speaking, it has not been usual in defining cross-elasticity to restrict the direction of the price-change. However, I believe most readers will accept, without quotation of chapter and verse, that invariably discussion has proceeded, either explicitly or tacitly, in terms of a price-cut. For the rest, it seems to have been assumed automatically that the same characteristics would attach to a rise in price. However, a price-cut involves the reduction of one price in relation to all others, whereas a price-rise implies the reduction of all other prices in relation to one. Where substitution in all directions is not continuous (see the latter part of footnote 10), the symmetry between a price-cut and a price-rise will not generally hold. For a more detailed discussion of this point, see my "A Kinked Demand Curve for Monopolistic Competition," *Econ. Record*, May 1953, XXIX, 19-34.

stitution) coefficient, except that it specifically excludes the case of a rise in p_i.

It should be noticed that this definition of cross-elasticity of demand makes no reference to the supply restrictions which Bishop rightly deplores. Moreover, it is clear that this cross-elasticity, freed from supply qualifications, is a coefficient of substitution. Indeed, this was precisely the purpose of its original introduction by Kaldor.[5] The aim was to provide a more satisfactory criterion of substitutability than that of physical description of the products. It was to meet the difficulty, as Triffin puts it, that "the competition may be keener between Ford and Rogers Peet than between Ford and Rolls-Royce."[6] And certainly this conception of cross-elasticity has persisted in the textbooks, at least in certain chapters of them. Thus, for example, Stigler tells us: "The cross-elasticities provide a convenient index of the readiness with which consumers substitute one commodity for another."[7]

In the classical tradition, it was held (correctly) that two criteria are necessary to define market relationships: (1) a substitution criterion, and (2) a numbers criterion. Triffin (as well as Kaldor, Stigler and others) was clearly correct in using price cross-elasticity as a substitution criterion; and, on this score, Bishop's criticism—that Triffin's interpretation of cross-elasticity is "one-sided" because it takes no account of the "scale of numbers"[8]—completely misses the mark. Indeed, it is from attempts to use price cross-elasticity as a numbers criterion, and in particular to use it as *the* criterion of oligopolistic interdependence, that confusion has inevitably arisen. High cross-elasticities are certainly a *necessary* condition for oligopoly, since price interdependence requires that the products concerned should be good substitutes. But further conditions are needed to satisfy the numbers requirement.

Cross-elasticity of demand as we have defined it, *i.e.*, as it is usually defined, is then, a coefficient of *substitution;* it is not a function of numbers. In fact, the supply restrictions upon cross-elasticities, which Bishop convincingly rejects, were allowed to intrude in the belief, mistaken as we shall see later, that this attached a numbers significance to cross-elasticity of demand. Yet Bishop, having abandoned these quite inappropriate supply qualifications, says: "The truth of the matter, of course, is that the value of E_{ji} depends on *both* the scale of numbers and the scale of product homogeneity-heterogeneity; and consequently it is not a sure clue to either, separately."[9] While this displays a commendable spirit of compromise, the conclusion is not correct. Indeed, if it were correct, then cross-elasticity of demand, not being a unique measure of anything, would have little purpose to serve and might be rejected out of hand.

The cross-elasticity of demand E_{ji} is a measure of the rate at which j cus-

tomers will move to product i in response to a reduction in the price i. From the indifference function of each individual j customer, we may deduce the rate at which each such customer will substitute product i for j. By summation, in the manner of the Marshallian demand schedule, we may construct a cross-demand schedule (q_j plotted against p_i) for the product j with respect to the price of product i. This will give us the rate at which j customers as a whole will substitute product i for product j.[10]

But, whereas cross-elasticity of demand is a function of the rate at which consumers will substitute the one commodity for another, own-elasticity of demand depends, not only on the rate of substitution between individual products, but also upon the *number* of substitutes available. After all, as Bishop himself stresses, own-elasticity of demand is a measure of "total substitutability," *i.e.*, the substitutability between the "own" product and the collectivity of products which make up its competitive field. It is surely obvious that any change in the variety or number of products within this competitive field will affect the value of own-elasticity of demand.

Let us pursue this question of the relationship between cross-elasticity and own-elasticity of demand further. For this purpose, we need to make a slight change in our definition of elasticity and cross-elasticity. Usually, elasticities are expressed as a ratio between a percentage price change and a percentage *output* change. However, under differentiated competition, units of ouput, as between firms, are not strictly commensurable. Therefore, instead of output, we now insert *sales*, *i.e.*, output in value terms; and to signify the change we substitute in our elasticities Q_i for q_i. We further suppose that the total value of sales lost by any firm j in response to a unilateral price-cut by i will accrue as additional sales to i. (This assumption is equivalent to neglecting the income effect of the price change.) Then, on this basis, own-elasticity of demand may be readily expressed in terms of the array of cross-elasticities:

[10] Cross-elasticity of demand for an individual consumer, which we may denote by E, is given by $E_{ji} = k_i\sigma - k_i\Upsilon_j$, where k_i is the fraction of income spent on i, σ is the elasticity of substitution between i and j, and Υ_j, is the income elasticity of demand for product j. (See J. R. Hicks, and R. G. D. Allen: "A Reconsideration of the Theory of Value," *Economica* (N. S.), May 1934, I, 201-2.) Then, if we neglect the income effect as we are entitled to do when only a fraction of income is spent on any one commodity, individual cross-elasticity of demand is a simple function of elasticity of substitution, σ. Firm cross-elasticity is the weighted average of these individual cross-elasticities.

Actually, this is not the whole story, because in conditions of pure monopolistic competition, if I may coin an expression, the process of substitution will not generally be continuous, *e.g.*, as in the case of substitution of one brand of toothpaste for another. Rather, in this situation, there would be a critical price ratio at which total expenditure on the one product (abstracting from income effects) would be shifted to the other. In terms of indifference curves, this case would be represented by a curve of infinite elasticity of substitution, but with a slope (marginal rate of substitution?) different from unity. Here, resort must be had to indirect methods to translate consumer preferences into cross-elasticities. Incidentally, it will be noticed that these cross-elasticities (finite) are more appropriate indices of substitutability than the elasticities of substitution which are infinite. However, this is a digression. My purpose here is only to show that cross-elasticity is directly related to the theory of consumer choice which, of course, is essentially a study of substitution. After all, the concept of cross-elasticity was born in the London School which, at the same time, was also nurturing the neo-Paretian analysis.

$$- E_{ii} = \frac{Q_j}{Q_i} E_{ji} + \frac{Q_k}{Q_i} E_{ki} + \cdots + \frac{Q_n}{Q_i} E_{ni} + \frac{Q_o}{Q_i} E'_{io} + \frac{Q_p}{Q_i} E'_{pi} + \cdots + \frac{Q_s}{Q_i} E'_{si}, \tag{1}$$

where the E_{ji} denote cross-elasticities of the first order of importance and the E'_{oi} denote those of second-order significance.[11]

For convenience, we assume: (1) that the first-order cross-elasticities are all equal, *i.e.*, the $E_{ji} = E_{ki}$, and that the second-order cross-elasticities are all zero; and (2) that all products are substitutes, *i.e.*, none are complementary, so that we may take the arithmetical value of elasticities without ambiguity, and so speak of larger or smaller elasticities without regard to sign. Then, on these assumptions, we may rewrite (1) in the simpler form:

$$E_{ii} = \frac{Q_j + Q_k + \cdots + Q_n}{Q_i} E_{ji} \tag{2}$$

$$\text{or, } E_{ii} = \frac{\text{Non-}i\text{ Output}}{\text{Output of } i} E_{ji} \tag{3}$$

Now, if the concept of numbers means anything in relation to a group, it expresses a relationship between firm output and total group output. If numbers are large, the firm's share in group output is small; and conversely if numbers are few. Then it is easy to see from (3) that any change in firm i's share of group output will, other things remaining the same, involve a corresponding change in own-elasticity of demand, E_{ii}. Take, for example, a decrease in numbers, *i.e.*, an increase in i's share of the market. This must necessarily involve a decreased elasticity of demand for firm i, since, *ex hypothesi*, the size of the market from which sales may be attracted has contracted in relation to i's own output. Although own-elasticity of demand depends on numbers in this fashion, cross-elasticity does not. This is so because the sales lost by any firm j in response to a price-cut by another firm i are related to the output of firm j. Hence, so long as the proportions between j customers of various degrees of sensitivity are unchanged, any increase (or decrease) in j's share of the market will affect the numerator and denominator of the cross-elasticity ratio in the same proportion.

The reader will not have failed to notice that our equation (3) expresses the same relationship as Bishop's so-called "numbers equivalent" which he writes $-E_{ii} = (n_i - 1)E_{ji}$. Also, it will be clear that the essential difference between

[11] *Cf.* Stigler, *op. cit.*, p. 235: "The group may be defined as all firms whose cross-elasticities are greater than some constant. This constant can best be chosen in any particular problem by ranking the cross-elasticities and considering a group to end where a considerable gap appears in the array of cross-elasticities." Interestingly enough, most economists would accept this procedure. But many do not seem to realize that in accepting this technique, based as it is on the notion of a gap in the chain of substitutes, they are accepting cross-elasticity as a valid substitution criterion.

Bishop's interpretation of this relationship and that given here is that, whereas Bishop treats cross-elasticity of demand as the dependent variable when n_i changes, for us it is own-elasticity which is dependent. Indeed, Bishop's argument always proceeds on the basis: *Given* own-elasticity of demand, then cross-elasticity will be large or small according as numbers are small or large. But, it is fair to ask, by whom or what is own-elasticity of demand given—apart from by the textbooks—except in relation to the closeness and the number of the individual products available as substitutes, the "total substitutability" as Bishop describes it. It is cross-elasticity which measures the closeness of the substitutes and is therefore the natural substitution criterion. Own-elasticity is then determined by the order of the cross-elasticities and the number of them.

This argument is best demonstrated by considering the case of homogeneous competition. In this case, cross-elasticity of demand will be the same whether there are two firms (pure duopoly) or 2,001 firms (pure competition), since cross-elasticity in both situations will be equal to the reciprocal of the percentage price-cut.[12] But own-elasticity of demand for the pure competitor will be much higher than for the pure duopolist. Although, of course, both elasticities may be made as large as we like, if we make the price-cut small enough, elasticity of demand under pure competition will always be much the higher for any given price-cut, however small. Indeed, if the firms in each group were symmetrical, own-elasticity in the pure-competition case would be just 2,000 times that in the duopoly case.[13] It follows as a corollary that, with any given price-cut, we can always make own-elasticity of demand, but not cross-elasticity, as large as we like by making our firm's share of total output small enough, *i.e.*, by making numbers large enough.

At the other end of the scale of substitutability, our interpretation of cross-elasticity is also the natural one. By contrast, Bishop's conception of the relationship between cross-elasticity and own-elasticity leads to paradoxical results when applied to "pure monopoly." In this case, own-elasticity of demand will be finite, while cross-elasticities will be very small or zero. Hence, their ratio—Bishop's "numbers equivalent"—will be very large indeed. And this Bishop frankly confesses, for he says that in this case the numbers equivalent "must be more or less *uniformly* high with respect to all other firms, without exception."[14] At best, this can hardly be said to be a happy choice of terms. Triffin, on the other hand, would describe this situation as one in which the cross-elasticities of demand (measuring the substitutability of products) are more or less uniformly *small*. Surely this is a more apposite description. This becomes obvious as soon as we put the question: Is pure monopoly non-oligopolistic because of the absence of close substitutes (failure of the substitution condition) or because of large numbers (failure of the numbers condition)?

[12] Since for homogeneous competition $\delta Q_j/Q_j$ will always be equal to unity.

[13] It will be remembered that we have excluded supply conditions from our definition of cross-elasticity. Hence, a price-cut by a purely competitive firm must be considered, conceptually, to capture the whole market.

[14] *Op. cit.*, p. 800.

It should be stressed that nothing in the foregoing argument depends on Mrs. Robinson's notion of products "coming closer together" or of new firms "coming in between" old firms, a conception which has been the subject of debate from time to time.[15] Mrs. Robinson, it will be recalled, argued that:

> . . . if the new firms were set up, so to speak, in between the old firms (either geographically or in respect of special qualities which appeal in various degrees to different customers) . . . the difference, from the point of view of buyers, *between any one firm and the next* would thus be reduced, the customers of each firm would become more indifferent, and the elasticity of demand would be increased.[16]

This is a valid argument.[17] But it is important to recognize that there are two effects involved here: not only an increase in numbers per se (the numbers effect), but also a change in the distance between individual products, as is indeed stated in the italicized phrase (the substitution effect).

The conceptual distinction between the substitution and numbers effects becomes clear when we consider that the notion of products "coming closer together" in no way depends on increasing numbers. It could equally well come about, for example, as a result of an all-around reduction in transport costs or of a technically inspired move towards greater standardization of existing products. In these cases, numbers would remain unchanged; but cross-elasticities, and hence own-elasticity, of demand would increase. On the other hand, an increase in numbers need not *logically* imply any change in the degree of substitutability between individual products, as for example when the entry of new firms does not alter the "distance" between any two products, as indeed will always be the case with homogeneous competition.

However, in the real world of differentiated products, a change in numbers will almost certainly involve some rearrangement of consumers' preferences;[18] and hence some change in cross-elasticities of demand. This effect will usually be in the same direction as, but remains conceptually distinct from, the numbers effect. The important fact is that cross-elasticities change, not in virtue of the change in numbers as such, but because of the change in substitutability which will usually be *associated with* a change in the product-structure of a group.

It is from confusion of these two effects, it seems to me, that has arisen the

[15] In particular, during the 1938 debate between Chamberlin and Kaldor in the *Quart. Jour. Econ.*

[16] Joan Robinson, *Economics of Imperfect Competition* (London, 1933), p. 101. My italics.

[17] *I.e.*, given Mrs. Robinson's condition: "If the new firms were set up in between the old firms." The fact that an increase in the numbers of firms *may* involve merely an increase in area and not in density—a point made much of by Chamberlin—is irrelevant to the *particular* argument in question.

[18] Strictly speaking, an increase (say) in the number of firms will not of itself alter consumers' preferences *as between* the old products. Rather it will establish between the old firms and the new firms, and between the new firms themselves, a new set of cross-elasticities, which may be larger or smaller than existing cross-elasticities. (In Mrs. Robinson's example they will, of course, be larger.) Nevertheless, the change in numbers will imply some redistribution of consumers between firms and this will, in general, affect the pre-existing cross-elasticities also.

"third force" view, as represented by Bishop, for example, that cross-elasticity is a function both of product substitutability and numbers. The clear implication of this view is that the effect of a change in numbers upon cross-elasticity cannot be theoretically determined, but is an empirical question only to be answered by reference to the facts of any given situation. But this approach is theoretically misleading. In so far as a change in the number of firms (products) changes the opportunities for substitution and the pattern of consumer attachments, it changes the pattern of cross-elasticities. But the important point is that it changes cross-elasticities via changes in substitutability or, if you like, via changes in the complex of consumers' preferences which theory has almost universally taken as data. However, there is no essential connection between such changes and changes in numbers in the sense used throughout this paper and by Bishop. This latter conception of numbers relates to the ratio of firm to group output, and changes in this ratio may clearly occur independently of any change in consumers' scales of preference.[19]

Since the matter is of fundamental importance for formal analysis, perhaps it is well to attempt to pinpoint the source of the long-standing confusion of cross-elasticity with numbers. In the old scheme—when commodities were different in kind, not merely in degree—numbers were determined as a simple arithmetic relationship between the capacity of any one firm and the total market supply of the commodity in question. Thus, if a firm's capacity were small compared with total output, the situation would be one of pure competition, because any additional supply it could add to the market would, when "spread over" that market, affect other suppliers only to a negligible degree. On the other hand, if a firm's potential capacity were large in relation to total supply, oligopolistic implications would arise.

This conception was adapted by Chamberlin to the general case of monopolistic competition. Thus, in a formulation which he still finds "unobjectionable,"[20] he defined the "large group" as follows:

> Specifically, we assume for the present that any adjustment of price or of "product" by a single producer spreads its influence over so many of his competitors that the impact felt by any one is negligible and does not lead him to any readjustment of his own situation.[21]

It is but a short step from here to those "half-breed supply-demand cross-elasticities" which Bishop denounces, a step, incidentally, that Chamberlin himself

[19] Perhaps the distinction is best made clear by an illustration. Imagine that a sectional increase in i customers' incomes results in a doubling of purchases from firm i, the outputs of all other firms in the group and the whole complex of consumer preferences remaining unchanged. Own-elasticity of firm i will approximately halve. By contrast, the cross-elasticities will not be affected, except in so far as the alteration in income shifts the margin at which substitution takes place. Since, when we speak of substitutability, we mean substitutability at the margin, there is clearly a sense in which we may take cross-elasticity, but cannot take own-elasticity, as data given by the total map of consumers' preferences.

[20] A Comment on Bishop's article, *Am. Econ. Rev.*, Dec. 1953, XLIII, 913.

[21] *Theory of Monopolistic Competition*, 3rd ed. (Cambridge, Mass., 1938), p. 83.

seems to have taken in his more recent work.[22] It would take me too far from the present purpose to discuss here the validity of Chamberlin's formula as a numbers criterion. But I do wish to dispute its relevance to the concept of cross-elasticity of demand.

Let us consider Chamberlin's formula in terms of a price-cut. Now it is clear that we must invoke some sort of supply restrictions if we are to make any sense at all of his conception of the effect of a price-cut being "spread over" a given number of rival firms. This is so because, theoretically, we can make the increment of sales to the price-cutting firm, and therefore the amount to be taken from rivals, as large (small) as we like if we make the price-cut large (small) enough. This follows immediately from the fact that, *ex hypothesi,* the relationship between a price change and a quantity change under conditions of monopolistic competition is always a *finite* one. Therefore, the increment of sales accruing to a price-cutting firm, and hence the amount taken from each rival, cannot be determined, unless appeal is had to some consideration of supply.[23] Now it is possible to argue that the amount by which a "large group" seller may increase sales is limited by supply factors. But, the smaller is a firm's potential capacity, the smaller need be the price-cut to take up this capacity; and since cross-elasticity of demand is the ratio of the quantity change to the price change, its value will not be affected by any considerations of supply.

It is perfectly true, of course, that, with given rates of substitution, the greater the *number* of competitors, "the less the price reduction necessary to secure any desired increase in the sales of A . . . And . . . the less the effect of any given increase in the sales of A on the sales of rival products. . . ."[24] However, since the effect of (say) greater numbers is (1) to reduce the price-cut required to achieve any predetermined result; and (2) to reduce the amount which it is necessary to take from any individual competitor, the cross-elasticities of demand are unaffected, because the numerator (percentage sales loss) and the denominator (percentage price-cut) are changed in the same proportion. Hence, *cross-elasticity of demand is independent of numbers.*

Since the idea of cross-elasticity as a measure of substitutability seems simple and straightforward enough, or at least so it has appeared to a good many writers, it may well be asked why its general adoption has been so strenuously resisted. The answer, I believe, is to be found in the implications which stem from its acceptance.

[22] For example, "Measuring the Degree of Monopoly and Competition," a contribution to *Monopoly and Competition and Their Regulation,* E. H. Chamberlin, ed. (London, 1954), esp. Pt. 4, pp. 262-67. More recently, however, he has retreated from this position and reverts to his original definition of isolation which I have quoted in the text above. He now says, "It should be noted that zero cross-elasticities, though sufficient, are not necessary to isolation in this sense; and also that in the vexed case of pure competition, *however one may rule as to the value of the cross-elasticity coefficient,* a single seller is isolated in the sense described." (Comment on Bishop's article, *op. cit.,* p. 913.) In short, he now admits there is no necessary relation between his large-small numbers criterion and cross-elasticity of demand.

[23] Bishop is overgenerous in saying that attempts to qualify cross-elasticities with supply restrictions have been confined to homogeneous competition. *Op. cit.,* p. 781.

[24] G. J. Stigler, *op. cit.,* p 235.

The argument advanced in this paper is essentially the same as that put forward by Kaldor in the 1938 controversy with Chamberlin. During that debate, it will be recalled, Kaldor regarded as "crucial" the proposition that "a shift of the [demand] curve to the left will increase the elasticity of demand at the equilibrium level of output. . . ."[25] And since such a shift to the left is associated with an increase in the number of firms, the "curves become more and more elastic with an increase in numbers. . . ."[26] Chamberlin rejected this proposition and reiterated his opposition to the idea that "differentiation of the product (in my sense) may be exorcised by the process of merely increasing the number of firms."[27]

Chamberlin was perfectly correct in asserting the latter, as he was wrong in rejecting the former, for it is clear that, no matter how small may become the output of a firm as the result of increasing numbers, there may still be a proportion, and even a constant proportion, of customers who will be prepared to continue paying something more for the product of that particular firm than for any of its substitutes. Product differentiation remains; and upwards elasticity of demand, *i.e.*, elasticity in respect of a price-rise, does not necessarily increase as output contracts in relation to group output. Indeed, as output contracts the firm may be left with only a hard core of its most loyal customers. Elasticity to a price-raise may actually decrease.

Thus, we arrive at the position where, as a firm's output contracts in relation to group output, its downward elasticity, E^d, increases (*vide* Kaldor), while its upward elasticity, E^u, may be constant or even decreasing (*vide* Chamberlin). And both points of view are correct. The seeming contradiction, which has persisted from the 1938 debate to Bishop's work in 1952, is only a contradiction so long as we cling to the preconception, which has no real basis except in the economist's penchant for simple stable equilibria, that E^d should approximate to E^u, *i.e.*, that the demand curve under differentiated competition should necessarily be smooth.

On a subject pregnant with misunderstanding, it is perhaps well to conclude by stating briefly what is *not* implied in my argument here. Firstly, although I have argued that Triffin's use of price cross-elasticity as his substitution criterion is, with the qualification mentioned, unexceptionable, I would not be prepared to accord the same support to his numbers criterion. The so-called "quantity cross-elasticity" by which he distinguishes between large and small numbers is purely definitional. At no point does Triffin postulate the conditions of demand or supply that determine the value taken by his numbers coefficient. Secondly, in so far as the degree of monopoly or competition may be expressed in terms of elasticities of demand, which is certainly not so in the case of oligopoly for instance, I believe it is own-elasticity, measuring total substitutability, which is the appropriate index. I would agree with criticisms of Triffin's suggested use of cross-elasticity in this connection. It should, I think, occasion

[26] *Loc. cit.*

[27] Reply to Kaldor, *Quart. Jour. Econ.*, May 1938, LII, 531.

no great surprise that a measure of monopoly or competition which involves both substitutability and numbers is more appropriate than one merely measuring substitutability.

R. HIESER*

* The author is a research scholar in the Australian National University, Canberra.

Reply

With respect to my own article, the principal issue raised by Hieser's interesting paper concerns the comparative merits of E_{ii} and E_{ji} as indices of the homogeneity or heterogeneity of products. In commenting on this question, I shall limit my discussion for the most part to the very special case of isolated, symmetrical groups of n rival firms.

In such cases, Hieser and I agree that the ratio $-E_{ii}/E_{ji} = n - 1$ reflects the "numbers" criterion to at least a fair approximation (p. 376). We also agree that the classification of market relationships requires a "substitution" criterion as well. We differ, however, in that I prefer the own elasticity E_{ii} for this purpose, while Hieser prefers the cross-elasticity E_{ji}. At bottom, this difference between us is definitional; but it is well worth debating which definition is the more useful analytically. For my part, I acknowledge that the cross-elasticities E_{ji} and E_{ij} indicate the substitutability between the ith and jth products; and Hieser seems to agree, in turn, that E_{ii} reflects what I called the "total substitutability" between the ith product and all others taken together—or all others within the relevant group when there is no significant substitution between the ith product and others outside that group (p. 375). We would further agree, I take it, that both "total substitutability" and the "individual substitutability" between pairs of products have their own respective significances. It remains, therefore, for me to indicate my reasons for preferring E_{ii} as the more useful substitution criterion for the specific purpose of classifying market relationships. I am especially grateful for the opportunity to do so; for Hieser's note has made me belatedly aware that I have never given anything like a complete explanation of my choice in this respect.

In reply to the first round of criticisms of my article, it was necessary for me to emphasize that a remarkably close approach to pure competition is consistent with very *large* magnitudes of E_{ji}, provided only that $-E_{ii}$ is all the larger—such that $-E_{ii}/E_{ji} = n - 1$ is also large.[1] At the same time, I also observed that "cross-elasticities are not *necessarily* high in atomistic competition."[2] This goes to the heart of the question as to the relative merits of E_{ii} and E_{ji} as the preferred criterion of product homogeneity or heterogeneity in the context of market classification. I must now emphasize that a remarkably close approach to pure competition is also consistent with very *small* cross-elasticities, provided that $-E_{ii}$, while itself very large, is small relative to n—such that $-E_{ii}/(n - 1) = E_{ji}$ is small.[3]

[1] "Reply," *Am. Econ. Rev.*, Dec. 1953, XLII, 916-17.

[2] *Ibid.*, p. 917, n. 2 (original italics).

[3] There is a quite intriguing symmetry—and complementarity—between this reply and my former one. There I had to defend my "numbers" criterion against the view, originally taken by Chamberlin among others and subsequently maintained in a somewhat different

Suppose, for example, that there are 1,000,001 firms in an isolated, symmetrical group, and that each $E_{ii} = -5{,}000$. For all practical purposes this hypothetical industry is a purely competitive one, because n is very large and the other-prices-constant demand facing each individual firm has an elasticity hardly distinguishable from infinite. Yet $E_{ji} = -E_{ii}/(n-1)$ is .005! With still higher numbers and the same E_{ii}, obviously, cross-elasticities can be made indefinitely small.

Now, if E_{ji} is specified as *the* measure of "substitutability," in accordance with Hieser's preference, it must at least be conceded that a situation can closely approximate pure competition even though the products of *pairs* of rival firms are only very weakly substitutable. In short, while high *total* substitutability is a necessary condition in order that pure competition may be closely approached, high *individual* substitutability is not. True, we speak of product "homogeneity" as a necessary condition for pure competition; but, in my view, the relevant version of that concept concerns the substitutability among *all* the products in the relevant group, rather than that between merely successive pairs of them. That is why I prefer to specify the "homogeneous-product" requirement of pure competition (and pure oligopoly) in terms of a high magnitude of E_{ii}, rather than in terms of E_{ji}.[4]

Similarly, when products are significantly heterogeneous or differentiated, this also seems to me to be most reliably reflected by the moderate or low absolute magnitudes of E_{ii}. Consider, for example, a symmetrical, isolated group of three oligopolists, such that each $E_{ii} = -10$ and each $E_{ji} = 5$. To me, this is a significantly *differentiated* oligopoly, because E_{ii} is significantly different from infinity. In particular, I would say that there is a much lower degree of product homogeneity in this industry than in the all but purely competitive one where every $E_{ii} = -5{,}000$. Yet Hieser would have to classify this significantly differentiated oligopoly (with $E_{ji} = 5$) as exhibiting a much *greater* degree of product homogeneity than the above situation of near-pure competition (with $E_{ji} = .005$). In my contrasting view, this species of three-

form by Fellner, that numbers—and, more generally, the distinction between the presence and absence of oligopoly—are reliably reflected by the magnitude of E_{ji} alone. I am pleased to have Hieser with me on that phase of the argument; and I am also pleased to have his support for Triffin's view and my own—as against Chamberlin and others—that supply restrictions should not be allowed to intrude on the elasticity concepts used in market classification. At the same time, it is Chamberlin and I who are arrayed against Hieser and Triffin as to the relative merits of E_{ii} and E_{ji} as the preferred measure of the degree of heterogeneity of products.

[4] To be sure, if the products of a *given number* of rival firms are visualized to become more and more nearly homogeneous, both E_{ii} and E_{ji} go to infinity—precisely because their ratio—$E_{ii}/E_{ji} = n-1$, remains constant. Hence, when products are strictly homogeneous, it would not matter whether we specify that condition as implying infinite E_{ii} or infinite E_{ji}. That is why I refer to instances of only near-homogeneity to weigh the comparative merits of the two coefficients as the preferred measure of this aspect of the classificatory problem.

On the other hand, if we visualize *both* $-E_{ii}$ and n as approaching infinity, E_{ji} may be anything at all between zero and infinite—as I also pointed out in my "Reply," *op. cit.*, p. 920. This again emphasizes that a large E_{ji} is not a necessary condition as pure competition is merely approached.

firm oligopoly would not exhibit as high a degree of product homogeneity until $E_{ii} = -5{,}000$ (with $E_{ji} = 2{,}500$).[5]

While definitions are never right or wrong, but only more or less useful, I do feel that Hieser's fails to accord with the practical distinction that the market classifier wishes to make between substantially homogeneous and significantly differentiated products. At the same time, I should like to acknowledge the paradoxical aspects of the matter. If only because there is a strong tendency to think of substitution as taking place between just *pairs* of products, E_{ji} does have a certain commonsense priority as a measure of substitutability. On the other hand, if E_{ji} is to be used in classifying market relationships, at the very least its *significance* as a measure of product homogeneity or heterogeneity within the relevant group requires the additional consideration of the number of firms with which the ith firm experiences similar cross-elasticity magnitudes.[6] This difficulty is avoided if the concept of total substitutability is used in the first place. This seems to me to be the better choice, both because market relationships involve much more than just the relationships between pairs of firms, and because—for the purpose of market classification—we are less interested in the substitutability between pairs of products than in some measure of the homogeneity or heterogeneity of products as supplied by the entire group of firms that make up any given firm's competitive field.

When Hieser finds a "basic confusion" in my proposals (p. 373), I do not understand him to be accusing me of any error of either fact or logic. Rather my transgression is that of preferring my own measure of substitutability to his. The same thing is true when Hieser characterizes as "not correct" my statement that "the value of E_{ji} depends on *both* the scale of numbers and the scale of product homogeneity-heterogeneity" (quoted above, p. 374). This would indeed have been incorrect if I had chosen E_{ji} as my measure of the homogeneity or heterogeneity of products. Actually, of course, I chose E_{ii}; so my conclusion still stands with respect to my own definition—as in the expression, $E_{ji} = -E_{ii}/(n-1)$.

Since Hieser and I agree as to the approximate validity of the equation, $-E_{ii}/E_{ji} = n - 1$ (or the "numbers equivalent," $n_i - 1$, when groups are either asymmetrical, imperfectly defined, or wholly amorphous), it seems to me pointless to argue whether "large numbers" imply a high value of $-E_{ii}$

[5] Naturally, the fact that this industry is oligopolistic rather than atomistic also implies that the other-prices-constant demand facing any one of the three firms (with E_{ii} is in some rigid sense a "dependent variable" (p. 377). While I did make use of the price-output decisions—any more than the other-prices-constant demand with $E_{ii} = -10$ will be the relevant one in our significantly differentiated oligopoly. The other-prices-constant demand function, on which both Hieser and I base our classificatory elasticities, closely approximates the demand relevant for the individual firm's decision-making only in nonoligopolistic situations.

[6] Indeed, Hieser seems to be at least on the verge of conceding this, in the sentence that includes the first part of the quotation from Stigler (p. 380). On the other hand, when he asserts with the emphasis of italics at the end of the same paragraph that "*cross-elasticity of demand is independent of numbers,*" I must again reply that it has no classificatory significance in distinguishing near-homogeneous products from significantly differentiated ones except in conjunction with numbers. To the extent that the italicized assertion is intended to have *empirical* validity, I shall comment on that question in just a moment.

or a low value of E_{ji}.[7] Similarly, I do not wish to commit myself to any hard and fast theory as to the actual effect on the E_{ii} and E_{ji} magnitudes of any *change* in the number of active firms in a particular industry.[8] It is true that I used phraseology such as this in my article (p. 786): "For any given value of E_{ii}, the larger is n . . . the smaller is E_{ji}." Again (p. 798), I spoke of the implications for E_{ji} "as differentiated products with given substitutability [*i.e.*, with given magnitudes of E_{ii}] are produced by larger and larger numbers of firms." But I also referred to this assumed constancy of E_{ii} as an "artificial assumption" (p. 798, n.); and in the remainder of that footnote I briefly indicated reasons why E_{ii} might actually be expected to increase and E_{ji} to decrease when the number of firms increases in some particular industry.[9]

More generally, such effects will obviously depend on the particular causes of the increase in the number of firms and the particular details of the consumers' tastes for the changing number and variety of available products. Hieser does not explicitly reject this view—indeed, he makes some concessions to it; but he also characterizes it as "theoretically misleading" (p. 379), on the ground that "a change in the number of firms . . . changes cross-elasticities via changes in substitutability." In Hieser's own terminology, however, this proposition is a definitional tautology; for he defines and measures substitutability only in terms of cross-elasticities. In the same context, Hieser also seeks to equate given consumers' preferences with given cross-elasticities but not with own elasticities. In my own view, all of the E_{ii} and E_{ji} coefficients are exactly on a par as given aspects of any given situation.

One possibility, I concede, is that the E_{ji} magnitudes might remain the same as numbers change. But even if this were always so as an empirical matter, it would not affect in any way—as I see it—the relative merits of E_{ii} and E_{ji} as the more useful classificatory measure of product homogeneity or heterogeneity. In other words, mere market classification, with which I was exclusively concerned, requires no special theory of the comparative statics of

[7] The same issue is also involved when Hieser expresses misgivings as to the implication that, in "pure monopoly," the numbers equivalent must be high with respect to all other firms (p. 377). Apart from the one-member group that the pure monopolist himself comprises, he belongs to no significant group other than that comprising all the firms in the whole economy. But we must still assure ourselves that the presumed "purity" of the monopoly is not compromised by any threat of oligopolistic interdependence with any other firm. It is then a matter of complete indifference, it seems to me, whether we state that condition in terms of uniformly high values of $-E_{ii}/E_{ji}$ or in terms of uniformly low values of $-E_{ji}/E_{ii}$. The former version suggests, at least by analogy, that the pure monopolist is a member of a large-number group embracing all firms in the economy, while the latter implies that he bulks small in the economy as a whole. In this case, furthermore, E_{ji} must itself be very small, since $-E_{ii}$ would always be no more than moderately large (significantly different from infinite) as an empirical matter.

[8] Thus I also wish to disavow explicitly the notion, which Hieser attributes to me, that E_{ji} is in some rigid sense a "dependent variable" (p. 377). While I did make use of the equation $E_{ji} = -E_{ii}/(n_i - 1)$ to show how cross-elasticity was related to both "total substitutability" and "numbers," I regard this equation as perfectly interchangeable with such transformations as $-E_{ii}/E_{ji} = n_i - 1$ (which I also used) and $-E_{ii} = (n_i - 1)E_{ji}$ (which Hieser prefers).

[9] In that footnote, unfortunately, there is a misprint: "*i*th" in the next-to-last line should be "*j*th."

actual changes in the numbers of rival differentiated products. It seems to me that Hieser confuses these more ambitious empirical questions with the quite separate problem of just classifying the alternative market relationships that may exist in any given situation. After all, the classificatory problem involves nothing more than identifying certain strategic coefficients that will be consistently related to those aspects of market relationships in which we are analytically interested.[10]

Hieser also believes that, in groups of firms supplying differentiated products, the other-prices-constant demand facing each firm will typically exhibit a highly distinctive kink—such that the downward elasticities (both own and cross) will markedly exceed the upward elasticities. Feeling that Hieser is quite fundamentally mistaken about this, I wish I might discuss the question at the length that it would require. Moreover, this is an issue of greater substantive and empirical significance than the one that I have discussed. But it is also a quite separate question; and limitations of space forbid my pursuing it at this time. Suffice it to say that my foregoing discussion may be interpreted as applying, from Hieser's point of view, to the downward elasticities only, or—when demands are smoothly continuous—to both upward and downward elasticities.

ROBERT L. BISHOP*

[10] For this reason, incidentally, I am somewhat puzzled that Hieser should criticize adversely one (but only one!) of Triffin's coefficients as being "purely definitional" (p. 381). The only relevant criticism of any such coefficient, it seems to me, must be based on whether it consistently reflects what it is supposed to reflect.

The Growth of American Unions: Comment

In a recent article in this *Review*[1] Irving Bernstein advanced persuasive argument, supported by considerable historical evidence, in support of the contention that the future of the American labor movement is quite bright. He cited figures to show that the trend of membership of organized labor was steadily upward during the period 1897 to 1953, not only in absolute terms, but also relative to the increase in the size of the total civilian labor force. This secular trend in "real membership" (membership as a percentage of the civilian labor force) is explained by the operation of four factors: the expansion of the labor force, the growing social acceptability of trade unionism, increasing homogeneity in the working force, and the extension of collective bargaining provisions for union security. His investigations led him to believe that these same four factors are likely to be operating in the future, assuring that organized labor will "grow steadily in the long run." It is apparent that to "grow steadily in the long run" encompasses a very wide range of possibilities, but it is clear from the entire context of the article that Bernstein is optimistic concerning the prospects for the future growth of organized labor. Bernstein also analysed the relation of the business cycle to union growth, and concluded that unionism will "suffer little or no loss in bad times."

[1] I. Bernstein, "The Growth of American Unions," *Am. Econ. Rev.*, June 1954, XLIV, 301-18.

The writer does not contend that Bernstein's inferences with respect to the future growth of organized labor are necessarily incorrect, but in the absence of more adequate analysis than that presented in this study he finds it difficult to accept them with the same degree of confidence as Bernstein. It is quite possible that certain weaknesses in Bernstein's analysis may have misled him into an overoptimistic appraisal.

In his analysis of the growth of the American labor movement Bernstein was concerned entirely with the determinants of the long-run trend and failed to consider the special circumstances which may have conditioned the growth during particular periods. This was especially unfortunate with respect to the period 1933 to 1946, since the highly favorable environment making possible the phenomenal growth of organized labor during these years is unlikely to exist again in the future. By 1933 the stage was set for a great union advance. Population growth and industrialization had created a pool of millions of industrial workers, largely concentrated in the urban centers, and for reasons that are well known these workers were almost entirely unorganized in 1933. Thus a tremendous potential existed at the beginning of this period. Within the climate of opinion toward group action created by the psychological impact of the depression, industrial unionism and the protection of a benevolent government provided the immediate stimuli for union growth. As a result, millions of workers flocked into the unions. The industrial expansion during the second world war created additional millions of jobs in those industries which lend themselves readily to organization, or which were already highly organized, thus providing further impetus to the union movement. In the postwar period, however, the labor movement has lost its momentum. Those segments of the labor force most susceptible to organization had by 1946 been fairly well exploited, and the postwar campaigns to penetrate those areas and those labor groups less amenable to unionization have met with only very limited success.

The great expansion of employment in the construction industry and in other industries which lend themselves readily to organization has made possible continued growth in the postwar period; however, since the membership increases have been concentrated primarily in these industries, the over-all increase has not been impressive. According to the estimates of the Bureau of Labor Statistics, membership in labor organizations rose from 15 million to between 16½ and 17 million, an increase of only two million or less, during the period 1946-53.[2] During this same period employment in nonagricultural industries increased by 8.5 millions. This experience is in sharp contrast to the war years (1940 to 1945) when organized labor drew 5.9 million additional members into its ranks while employment in nonagricultural industries rose by only 6.2 millions.[3] If the estimates of the Bureau are accepted as a reasonable approximation, the conclusion seems inescapable that a future large-scale union advance will be unlikely unless organized labor is successful in pene-

[2] Membership figure for 1946 from Bureau of Labor Statistics, *Brief History of the American Labor Movement* (Washington, 1947), p. 17 Membership figure for 1953 from BLS, *Directory of Labor Unions in the United States, 1953* (Washington, 1953), p. 2.

trating the main citadels of the unorganized groups—*i.e.*, the write collar employees, the trade and service employees, the employees in the smaller firms, the southern workers outside of Richmond and Birmingham, etc. The fact that organized labor has evidenced little ability to expand in these directions in the postwar period indicates that union growth in the future is likely to be slow.

In his discussion of the factors shaping the size of the American labor movement Bernstein failed to consider the long-run changes in the structure of the economy and the consequent changes in the locational and occupational structure of the labor force. As indicated above, these structural changes were one of the most important factors making possible the great union expansion from 1933 to the end of the war. There is, however, no reason to suppose that future structural changes will be so fortuitous from the standpoint of organized labor. The increasing complexity of our industrial system, the expansion of governmental functions, and rising real incomes are bringing about a decline in the manual segment of the labor force, that segment which has furnished the only fertile field for the union organizer. The South, and other areas of anti-unionism, have been expanding industrially relative to those areas which are more congenial to organized labor. The ultimate result of this development may be to lessen greatly the currently strong and widespread anti-union sentiment in these areas, but there is no assurance that this will be the case. A trend toward wide decentralization of industry in the not too distant future is a definite possibility. By shifting industry toward the smaller communities, such a development would increase substantially the organizational problems of the unions. These few examples of possible future developments suffice to indicate the fallacy of assuming that future structural changes will benefit, or will not be detrimental, to organized labor. It is possible, and in the writer's opinion probable, that they will create a continuously less favorable environment for the unions. In any case, conclusions concerning the future growth of the American labor movement based upon an analysis which does not include consideration of this important factor do not warrant a high degree of confidence.

In drawing upon historical evidence to support his contention that unionism "will suffer little or no loss in bad times" the author fails to consider the fact that, in comparison with past decades, a very much higher percentage of union members are now concentrated in those very industries which are most subject to cyclical decline. In 1950, the United Automobile Workers, Steelworkers, and Machinists alone comprised nearly 20 per cent of the total of organized labor, and these same three unions were responsible for over one-third of the total increases in membership which occurred from 1948 to 1953.[4] Also at present a much higher percentage of total membership is made up of workers in the unskilled and semiskilled groups than was true during most of the period under study by Bernstein. These workers are not as likely as skilled workers to retain their membership during periods of layoff. It seems reasonably certain, therefore, that a major decline in the level of business activity would substantially reduce union membership. Even the relatively mild and short-lived recession of 1949 reduced union membership by 200,000.

[4] Source: Bureau of Labor Statistics, *Directory of Labor Unions in the United States, 1949*; BLS, *Directory of Labor Unions in the United States, 1953.*

Future events may confirm Bernstein's optimistic predictions concerning the future growth of organized labor, but on the basis of available evidence it appears more likely that organized labor's advance for some time in the future will be slow. The rate of increase in total membership over the long run is unlikely to equal the rate for the postwar period, with actual setbacks occurring during periods of declining business activity. The future is, however, very uncertain and any conclusions must necessarily be highly qualified and tentative.

The Growth of American Unions: Comment

The most challenging conclusion in Irving Bernstein's recent article[1] is that "The conventional monocausal explanation for fluctuations in union membership, the business cycle, is without general validity." Bernstein attempts to show statistically that neither cyclical movements as a whole nor leading components of the cycle (specifically consumer prices, employment, wholesale prices, and industrial production) correlate significantly with unionism. He further concludes that cyclical changes are "useless" in understanding secular expansion in union membership and only sporadically helpful in respect to short-term changes.

On the affirmative side, Bernstein summarizes his findings as follows:[2]

> A multicausal system (including the cycle) is necessary to account for the rise of trade unionism. The primary forces that have shaped secular growth are the expansion of the labor force, growing social acceptability of unionism, increasing homogeneity in the working class, and extension of collective bargaining provisions for union security. In the short run membership has expanded sharply as a consequence of wars and very severe depressions. Unions, in other words, have been the beneficiaries of disaster.

Although we do not quarrel fundamentally with Bernstein's pluralistic explanation of union growth, our analysis leads us to conclude that he has minimized unduly the importance of the cycle in a multicausal system. We have assumed, as does Bernstein, that the business cycle may be adequately represented by the four series: cost of living (consumer prices), employment, wholesale prices, and industrial production. Bernstein found no meaningful relationship between "real" union membership (*i.e.*, the number of union members corrected by the size of the labor force) and any of the four economic factors cited.

In our investigation, we deemed it more reasonable to examine the relationship between the growth of unions during a given time period with the characteristics of the business cycle *during the previous time period* rather than, as in Bernstein's analysis, for the same time period. A time lag is reasonable because on the downturn union members rarely fall away at once and on the upturn it takes time to launch organization drives to attract new members and regain former members.

[1] *Am. Econ. Rev.*, June 1954.

[2] *Ibid.*, p. 317.

When a time lag of one year is used, the results are statistically significant. This is shown in the analysis given below.

Let Y_t = change in union membership during time period t,
X_{1t} = change in cost-of-living index during time period t,
X_{2t} = change in employment during time period t,
X_{3t} = change in wholesale price index during time period t,
X_{4t} = change in industrial production index during time period t.

Since the changes in the business cycle during a given time period must be characterized by all four values of X_{1t}, X_{2t}, X_{3t} and X_{4t}, the relationship may be investigated by using a multiple regression model. Let

$$Y_{t+1} = a_0 + a_1 X_{1t} + a_2 X_{2t} + a_3 X_{3t} + a_4 X_{4t}.$$

Using the data presented in the Bernstein article, the following estimated relationship may be obtained.

$$Y_{t+1} = 1.577 + \underset{(.45)}{.805}\, X_{1t} + \underset{(.80)}{.207}\, X_{2t} - \underset{(.33)}{.188}\, X_{3t} + \underset{(.19)}{.253}\, X_{4t}$$

The numbers below the regression coefficients are the standard errors of the regression coefficients. On the basis of these standard errors, it appears that the relationship between changes in union growth is not very strongly related to *any one* of the changes in the individual characteristics of the business cycle. However, changes in the cost-of-living index and changes in industrial production individually seem to bear the strongest relationship to changes in union growth.

In order to evaluate the *joint* relationship between the changes in the four characteristics of the business cycle and changes in union growth, the multiple correlation coefficient has been computed. We find that $R = .481$ and this is significant at the 5 per cent level. This indicates that there is a relationship between changes in the growth of unions during a given time period and changes in the four variables related to the business cycle during the *previous* time period when all of these variables are considered at the same time.

The foregoing analysis does not purport to show that the growth of unions may be completely explained by business cycles. However, it indicates that business cycles are an important factor in explaining union growth and casts serious doubt on the conclusion that cyclical movements and their leading components are "useless" for an understanding of union growth.

Reply

Both these comments express views that appear to differ from mine primarily in emphasis rather than in content. Hence the remarks here run the

risk of exaggerating the area of disagreement, because I shall deal only with substantive differences, starting with Fristoe.

In part, Fristoe may be classed as a "saturationist." This view, in essence, holds that the American labor movement stopped growing at the end of the second world war. The readily organizable areas had been cracked and only tough nuts remained—the white collar worker, the small town, the South. etc. My fundamental objection to this argument has already appeared in the article that led off this controversy and there is no need to repeat. Hence I shall comment now only upon matters not dealt with there.

The first point concerns Fristoe's citation of Bureau of Labor Statistics' estimates of union membership in 1946 (15 million) as compared with 1953 (16½ to 17 million). These figures, it should be noted, are not collected by the Bureau and "are not to be construed as data verified by Government."[1] The 1946 figure (14,974,000) is grossly in error because it estimates CIO membership at 6 million. As is well known, CIO has never revealed its actual membership and the 1946 figure is inflated by about 2 million. By deducting this amount, the result closely approximates Wolman's estimate of 12,980,000. The person formerly responsible for the BLS figure has herself reported 1946 membership (including Canadian) at 13,800,000.[2] The actual rise in the period 1946-1953, therefore, was in the neighborhood of 4 million rather than 2 million.[3]

The second comment deals with what Fristoe calls "the main citadels of the unorganized groups"—white collar, trade and service, small firms, and the South "outside of Richmond and Birmingham." The military image is unfortunate since workers in these areas, though more difficult than others to organize, hardly constitute a fortress against unionism. For the white collar and trade-and-service groups the excellent California statistics are suggestive, though, unfortunately, the series covers only the four years, 1950-1953. The 1,577,900 union members in the state in 1953 were divided between 522,000 in manufacturing (33.1 per cent) and 1,055,900 in nonmanufacturing (66.9 per cent). The industry groups in which white collar and trade-and-service employment predominates had the following number of members in 1953: public utilities (60,700); trade, wholesale and retail (185,400); eating and drinking places, hotels and other lodging places (93,600); motion picture production and distribution, theatres and other entertainment (76,400); miscellaneous services (86,400); and government (49,400). Together they totaled 551,900, or 35 per cent of all members. Further, there is evidence that membership in these groups has been increasing; between 1950 and 1953 it advanced 66,200 or 13.6 per cent.[4]

The notion that small firms are more difficult to organize than large is suspect on its face. Sophisticated students of the labor movement a generation

[2] F. Peterson, *American Labor Unions* (New York, 1952), p. 62. She reports unbroken growth between 1946 (13,800,000) and her terminal year, 1951 (15,300,000).

[3] The 1953 BLS estimate for the labor movement as a whole is not based upon an inflated CIO figure.

[4] State of California, Department of Industrial Relations, *Union Labor in California, 1950,* p. 13 and *Union Labor in California,* 1953, p. 11.

ago argued precisely the opposite in explaining the failure of the AFL in the mass-production industries. The extraordinarily high level of organization in the San Francisco Bay area, where there are no large firms excepting branch plants of nationwide corporations, is an obvious illustration to the contrary. Even more to the point, however, are the statistics of the National Labor Relations Board in collective bargaining elections. In the fiscal year 1953, for example, the Board conducted 6,050 of these representation elections. Of the 1,368 elections involving units with fewer than 10 employees, unions won 76.7 per cent; of the 3,884 involving fewer than 50, unions won 72.9 per cent; of the 4,720 involving fewer than 100, unions won 71.8 per cent; and of the 5,323 involving fewer than 200, unions won 71.4 per cent.[5] Obviously, unions are finding it worth while to organize small firms.

There is an almost universal tendency to underestimate the extent of union organization in the South, in which Fristoe appears to share. The rapid industrial integration of that region with the nation in recent years has been accompanied by a sharp increase in unionization. In the absence of regional statistics, this conclusion must be supported by a variety of sources. The BLS Community Wage Surveys for 1953-1954, for example, revealed the following percentages of plant workers in manufacturing covered by union contract: Dallas, 61; New Orleans, 63; Memphis, 78; and Atlanta, 57.[6] Nationwide corporations with branch plants in the South have almost invariably brought unions with them in such industries as automobiles, steel, rubber, meat packing, and aircraft. More than 90 per cent of some 40 southern pulp and paper mills are unionized, a higher incidence than any other region except the Pacific Coast. Meyers has estimated the extent of unionization in Texas for April 1953 as follows: manufacturing, 45-50 per cent; railroads, 100 per cent; maritime, 100 per cent; telephone and telegraph, virtually 100 per cent; bus transportation, 66 per cent; and interstate trucking, over 80 per cent.[7]

I concur with Fristoe's comment that the labor movement is relatively more vulnerable to depression now than it was in the past because it has organized the more cyclically sensitive industries and has a higher proportion of unskilled and semiskilled workers. It seems to me, however, that the long-term growth of unions could be affected by these considerations only if the business decline were of unusual severity and duration. There is no evidence that the comparatively mild fluctuations of 1948-1949 or 1953-1954 had any such effect. A laid-off unionist customarily stops paying dues but retains his membership; with re-employment he simply resumes payments. In other words, the relationship between a job and membership is loose in this context.

Finally, the differences between Fristoe's views and my own may be more of tone than of substance. On the basis of historic forces presently at work I would expect *gradual* growth in the size of the U.S. labor movement, leaving

[7] F. Meyers, "Factors in the Growth of Unionism in an Industrializing Area," unpublished manuscript, pp. 2-3.

aside such eventualities as war or a great depression. Fristoe appears to consider this a real possibility, but is inclined to emphasize the dark spots. I suspect that he is unduly pessimistic.

Davey, Jacobs, and Monroe are to be commended for suggesting the idea of a one-year lag, which, frankly, did not occur to me. As indicated in the original article, however, there is doubt in my mind as to the appropriateness of correlation analysis in this context; the coefficients were published initially only because they agreed with the results reached with several other methods. Hence the reader was advised to give these coefficients "the weight he thinks they deserve."[8]

This caution applies as well to the correlation analysis of Davey and his associates. The secular trend has not been removed from any of the series employed and all five experienced marked growth. Between 1900 and 1948, industrial production, employment, wholesale and retail prices, and union membership expanded in secular fashion. It is certainly not unreasonable to expect that part, and perhaps most, of the explanation for the correlation is to be found in secular rather than cyclical factors. There is, apparently, a tendency for the coefficient of multiple correlation between time series to rise when the number of series increases. In this connection it is worth noting that none of the individual coefficients was significant, and significance at the 5 per cent level was reached only with a multiple correlation. Finally, the fact that several series move together does not necessarily mean that there is a causal connection between them.

The central argument of substance is this: The trade union is a complex institution only partly sensitive to economic forces. These forces, in turn, are only in part cyclical. Hence it makes little sense to construct a theory of union growth about the cycle. It is far more meaningful to assume a multicausal system (including the cycle) at the outset.

I suspect that Davey, Jacobs, and Monroe would find little to take issue with in what has just been said. Again, the differences are mainly of emphasis.

Erratum

In the article "The Impact of Labor Disputes upon Coal Consumption," by C. L. Christenson, in the March 1955 number of this *Review*, the second line on page 96 was incorrectly inserted. The first sentence on the page should read, "While railroads with a figure of 132 per cent had duplicated that level in a few single months earlier, they had never before closed a year when reserves had been maintained continuously well above 100 per cent for all twelve months." In the second line of the middle paragraph on the same page, the reference in parentheses should be page 88.

BOOK REVIEWS

Economic Theory; General Economics

The Tools of Social Science. By JOHN MADGE. (New York: Longmans, Green and Co. 1953. Pp. x, 308. $4.75.)

Theory and Method in the Social Sciences. By ARNOLD M. ROSE. (Minneapolis: University of Minnesota Press. 1954. Pp. xii, 351. $5.00.)

On Theory and Verification in Sociology. By HANS L. ZETTERBERG. (New York: The Tressler Press. 1954. Pp. 78. $2.50.)

"If we are honest we have to admit that the first century of social science has left us somewhere short of victory." I do not want to be less honest than Mr. Madge is (p. 290) but I should like to submit that some twenty-four hundred years of known social science have left us where we are, and that we shall always be short of victory because there is no end to the battle for knowledge, social or natural. To Madge social science is only a hundred years young because for him it all began with the establishment of the positivist science of sociology.

The "tools of social science" to which Madge devotes his text are "documents" (37 pages), "observation" (27 pages), "the interview" (110 pages) and "experiment" (36 pages). The last is "the apex of scientific method." The "mental experiment is an invaluable dress-rehearsal but it is no substitute for the real thing." There "can often be an orderly progress through search of documents, through observations, through the various forms of questioning, before we are ready for the rigour of experiment" (p. 292). Has he no place for theory at all? Madge is willing to forgive the "theoretically inclined social scientist" because "the desire to explain and to unify social facts, the search for a consistent framework, these cannot be condemned even by the extreme empiricist, because this desire has motivated much valuable empirical research" (p. 291). But "too many hypotheses are based on ideal and logically tidy considerations . . ." (p. 118). "The only safe source of knowledge about human beings is what we can see and hear, and everything else is guesswork." The techniques described by Madge "have therefore an ostensibly behaviourist foundation" (p. 34).

With all his scientistic preconceptions, his ultra-empiricism, positivism, and behaviorism, Madge is also an adherent of epistemological relativism, of the coexistence of conflicting truths in social science. To him "the only tenable view is Mannheim's perspectivist view of many truths, each shared only by those who have shared experiences and have agreed between themselves on social aims" (p. 5). And "to postulate an objective social science is to ask for something which is probably unattainable, and may even be undesirable" (p. 6).

A clue to one of the sources of Madge's superstitions can be found in the

singular nouns in the title of his first chapter: "The Method of Social Science." If, instead of proclaiming the coexistence of competing truths, he came to recognize the coexistence of different methods and of several social sciences, he would be less myopic also in other matters and less liable to misguide his readers.

For every misunderstanding and misjudgment in Madge's book a pointed criticism and correction can be found in the book by Arnold M. Rose. The very first chapter (a paper which had won the 1952 prize of the American Association for the Advancement of Science for essays in social theory) contains a good statement on the nature of theory and on the testing of deduced hypotheses. But the best antidote to Madge's scientistic methodology can be found in Chapter 14 on "problem orientation versus method orientation." Rose quotes approvingly the psychologist Maslow, who protested against the "over-valuation of quantification for its own sake," against the "creation of a false and pernicious hierarchical system among the sciences," and against the "creation of a scientific orthodoxy, which in turn (a) tends to block the development of new methods, (b) tends to exclude many problems from the jurisdiction of science and (c) tends to make scientists 'safe' rather than daring" (p. 254).

Rose objects to the "primacy of method," according to which "a body of disciplines known as the 'behavioral sciences'—psychology, sociology, and social anthropology, plus a very small section of political science and economics—is distinct from a body of disciplines known as 'documentary sciences' —history, ethnology, political science, law, institutional and labor economics (the rest of economics is put in a class by itself)" (p. 249). In Chapter 15, on "Generalizations in the Social Sciences," there are, besides excellent comments on determinism versus probabilism, some admirable statements on social science as "a pile of discrete bits of knowledge" as against "an integrated body of propositions." "An adequate system of general propositions is based on an internally consistent set of assumptions and definitions, such that each proposition is capable of being logically deduced from the assumptions and definitions (in the manner of a theorem). The building up of an adequate theory—the shorthand term for the framework of assumptions and definitions as well as the propositions deducible from them—requires a constant interplay between theory and data in which the theory is regularly modified and new deductions are derived from it and once more tested by crucial facts" (p. 263).

Two chapters are explicitly addressed to economists: one on "The Potential Contribution of Sociological Theory and Research to Economics," and another on "A Deductive Ideal-Type Method." In the latter, Rose discusses the convertibility between inductive and deductive propositions and presents a good formulation of the distinction: "Inductive studies test the hypothesis that *b* follows *a* under specified conditions. Deductive studies seek to specify the conditions (assumptions) under which *b* must logically and inevitably follow *a*, and they pose for empirical research the question of the relevance of these conditions to any observable phenomena" (p. 340).

I do not know whether the Roses or the Madges are more representative of present-day sociology. But in this war of the Roses against the Magic of

Scientism the third book under review sides with the former. Hans L. Zetterberg's methodological program proclaims "(1) a concern with theories (definitions and hypotheses) rather than frames of reference (only definitions) . . . (2) verificational studies rather than descriptive ones, and (3) a concern with miniature theories rather than an inclusive theory" (p. 13). These "miniature theories," however, should be integrated, not isolated. For, "we explain something by demonstrating that it follows the laws of other phenomena. To ask for an explanation in science is to ask for a theory" (p. 9). Merely "to know the labels of phenomena and to know their distribution is not to explain them" (p. 14).

Zetterberg's observations on operationalism are illuminating. For purposes of verification "only those operational definitions that have a counterpart in a nominal definition are worth while. When verifying a theory, certain measurement devices may very well be worthless [and] irrelevant" (p. 34). The evaluation of the validity of certain operational definitions for a hypothesis formulated in terms of nominal definitions is shown to be one of the most significant steps in the verification of the hypothesis. Zetterberg's book is worth while and relevant for economists.

FRITZ MACHLUP

The Johns Hopkins University

The Share of Wages in National Income. By ASHOK MITRA. (The Hague: Centraal Planbureau. 1954. Pp. 113.)

Dr. Mitra's dissertation is a valiant attempt to cope with a problem whose fascination is exceeded only by its difficulty. Despite his ingenuity, his efforts are not altogether successful; however, he is to be congratulated upon the real contribution he has made.

The first chapter is a brief survey of classical, neoclassical, and Marxian distribution theories; the second is a critique of the Cobb-Douglas function as an explanation of labor's share. The criticisms of the latter are generally correct, although a better case could be made for the distributive implications of the "function" than the author's arguments would suggest.

Chapter 3 is a quite sound criticism of Kalecki's theory of income distribution. Mitra perceives clearly that Kalecki's theory is perilously close to a tautology; however, he does not point out that the scant empirical content this theory does possess is almost certainly false. Specifically; if it is assumed that the marginal cost curve in the Kalecki model is parallel to the quantity axis (*i.e.*, is "flat"), all other propositions in the theory can be deduced. And as I have argued elsewhere[1] (contrary to Mitra and others) it is not likely that the *relevant* marginal cost curve—for Kalecki's theory—is flat.

The author is (properly) critical of Kalecki's failure to measure the "degree of monopoly power" directly. Accordingly, in Chapter 4 he attempts to provide such a measure. As Mitra accepts both Kalecki's assumption that the marginal cost curve is flat and Lerner's definition of monopoly power (*i.e.*, *price minus marginal cost price*), his measure of "degree of monopoly

[1] "Rehabilitation of Partial Equilibrium Theory," *American Economic Review*, May 1952, pp. 191-2.

power" varies in the same direction as the ratio of price to average expenditure on wages plus raw materials. To my way of thinking this begs the question between Kalecki and the "marginalists." Furthermore, the statistical methods used are more courageous than delicate. However, despite these caveats, the chapter's finding that (contrary to Kalecki) the degree of monopoly power has not had a cyclical pattern in Britain, is both important and plausible.

In Chapter 5, the author offers an alternative model (for determining labor's share) whose inspiration he credits to Cournot. This model makes the wage share depend upon the following: the ratio of money wage rates to product prices; the rate of depreciation; the quantities of labor and imports (raw material) per unit of output; the number of competing sellers and the "zero demand price" (the intercept of some unspecified aggregative demand curve with the price axis). He then, in Chapter 6, deduces the effect upon the wage share of varying each of the above parameters; the most interesting of the results is that the wage share will *ceteris paribus* vary in the same direction as the share of raw material producers (*i.e.*, import suppliers).

The derivation of this result (pp. 65-66) is suspect because it involves partial differentiation of the wage-share function without consideration of the constraining identity among gross sales, labor income, nonlabor income, imports (raw materials) and depreciation. Nevertheless I believe Mitra to be close to the right answer—even though I would dispute his method of getting there. This chapter concludes with some applications of the model to the interpretation of British data; these are interesting, but not quite convincing.

It is unfortunate that Mitra's ideas must be strained through a very poor English translation. It is to be hoped that stylistic difficulties do not repel students, as the book merits attention.

MELVIN W. REDER

Stanford University

Christian Values and Economic Life. By JOHN C. BENNETT, HOWARD R. BOWEN, WILLIAM A. BROWN, JR., and G. BROMLEY OXNAM. (New York: Harper & Bros. 1954. Pp. xv, 272. $3.50.)

This summary volume in the series on Ethics and Economic Life produced by a study committee of the Federal Council of Churches is a miscellaneous collection made up of four parts, one of which discusses the topic announced in the title of the book. Another part comprises six chapters on international economics by William Adams Brown, Jr., who performs the excellent service of showing the pitfalls awaiting those who would rush thoughtlessly into this field with what might appear to be clear and evident Christian solutions. In addition there is a summary of the findings of the five other books in the series and three introductory chapters comprising an historical sketch by Bishop G. Bromley Oxnam.

The work most pertinent to the topic of Christian Values and Economic Life is that contributed by John C. Bennett, professor of Christian theology and ethics. Bennett advocates a middle way between the extremes of collectivism and individualism. He is for a mixed economy, or the present-day fluid type of capitalism, as the best system for assuring the rights of Christian in-

dividualism in an age of totalitarianism, and as the most promising for achieving the reforms suggested by Christianity.

Bennett is a Christian reformer, not a revolutionist, and a distinctive feature of his reform is that it is to be guided by the scientific analysis of economics and the technical knowledge of those familiar with economic facts. He goes beyond this announced purpose and shows ready acceptance of not only the analysis of economists but also their policy recommendations. Bennett's stand on the issues of progressive taxation, labor relations and social security places him in the political spectrum to the left of the public he is aiming at, the clergy and laity of American Protestant churches. Nevertheless, his writing should gain ready acceptance, for it is a popular presentation in the best sense of that phrase, and a solid contribution to the important work of advancing public understanding of economics and economists.

Bennett may be criticized for neglecting some of the fundamental questions raised by other writers in this field. For example, Is the predominant philosophy of the day compatible with Christian philosophy? Bennett draws heavily upon economists, who reflect the predominant philosophy of their times, and their thought may be, at least in part, antithetical to Christian philosophy. Coleridge, one of the earliest students of the relations between religion and economics, stressed the point that "the articles of our Church, and the true principles of government and social order, will never be effectually and consistently maintained against their antagonists till the champions have themselves ceased to worship the same Baal with their enemies." By Baal he meant the mechanic, Lockeian philosophy that was predominant in his age.

A second question often raised is: Do church and society face a fundamental and novel crisis today? This concern is expressed, for example, by Emmanuel Cardinal Suhard in *Growth Or Decline?* and by Wilhelm Röpke in *The Social Crisis of Our Time*. If we do face such a crisis, economic analysis of itself will not be a reliable device for detecting it or for suggesting all the solutions needed.

Outline of an Economic Theory. By BENJAMIN H. J. EIRÍKSSON. (Reykjavík, Iceland: Helgafell Publishing Co. 1954. Pp. 493.)

This book, which is the product of a Harvard doctoral dissertation inspired by the late Professor Schumpeter, attempts to reformulate general equilibrium theory. According to Eiríksson, Walras' system is only capable of treating the value and pricing of services because Walras had an unsatisfactory capital theory. But the serious problems of interest, money and business cycles spring from the valuation of "agents." Contemporary monetary and employment theory merely provide "makeshift solutions" for these problems. The road to a really integrated general economic theory, in Eiríksson's view, is by way of a satisfactory theory of capital and interest which can be blended with the Walrasian system. The major portion of the book is devoted to a new conceptual apparatus for handling the problems of capital, interest, and money.

Eiríksson's capital theory is essentially Austrian, but with a novel twist. In

the Austrian tradition, capital ("durable agents") is a means of "storing" the services of "original agents." The services of capital goods are substitutes for the services of original agents. According to Eiríksson, the essence of capital is this process of storing and substitution. In the orthodox Austrian capital theory, however, there are only two "original agents"—land and labor. But the capitalists nevertheless perform a "function" in production by means of their "saving" or "waiting" which makes the original agents more productive via the well-known roundabout methods of production. The reward for the "capitalists" is the famous "agio," as illustrated by the examples of growing trees and aging wine. It is with respect to this particular "functional" interpretation that Eiríksson departs from his masters.

Instead of two "original agents" (factors of production), Eiríksson introduces a third: money. Money is like the original agents of "land" and "labor" since its value does not depreciate with use. (Nondepreciability is the criterion for classifying an "original agent." One might raise the question, however, whether labor and especially land are in fact nondepreciable.) Money also makes the storing of original services (the creation of capital goods) possible. Money performs a "function" coordinate with traditional "land" and "labor." On this basis, Eiríksson attributes the gain on the accounts of capital agents to money as an original agent. The "agio" theory of interest therefore becomes a "service theory of interest."

With this apparatus, Eiríksson commences his analysis, which is overwhelmingly the application of the equalization principle of asset yields under various assumptions. There is a price level of services (flows) and a price level of agents (stocks). The "general rate of return" appears as a derivative from the respective stock and flow values. The "interest rate" is the rate of return on money as an "original agent." In equilibrium the rates of return on different agents, the "general rate of return" and the "interest rate" are all equal. Difficulties arise (which recall Hayek's business cycle theory) when the "general rate" does not equal the "interest rate" either because the "interest rate" is administered or because the "general rate" may not find its "natural" level due to inflexibility of service or agent prices. Also, problems arise when people "prefer" the "agent" money to other "agents" or services. Indeed, all problems appear as types of "disequilibrium" which result from either inadequate price flexibility, or "institutional rigidities," or an insufficient supply of money.

The attempted scope of this book is so vast that it is difficult to criticize it. One may complain that he does not like the concepts. But one man's concepts may be just as good as another's—it is often a matter of taste. Eiríksson, however, does spend an inordinate amount of time laboring his own notions; and the reader has an enormous job trying to keep straight just how Eiríksson's use of a term differs from someone else's. Moreover, one may not always appreciate Eiríksson's efforts to show how people like Keynes and Wicksell were "wrong" or treated only "special cases" simply because they did not use the same apparatus he does. Yet despite its apparant vastness of scope, there is nowhere in this book a clear statement of the forces that determine "the general rate of return." The best Eiríksson presents on interest rate determination is the proposition that the rate is determined by "preferences" for "agents"

vs. "services." One will look in vain for an evaluation of the relative merits of time preference, productivity, and liquidity preference as determinants of the rate of return. In general, this book is long on concepts and short on fruitful behavior propositions. Everything is explained in terms of "preferences." When positive behavior propositions appear, they are often questionable. For example, we are led to believe that higher rates of return on capital and higher wages always encourage more saving and a larger supply of labor. It is not too safe to base a "general" theory on propositions such as these.

To those who seek a grand theoretical system and who find the Austrian capital theory tradition congenial, this book will prove challenging. For those who share Frank Knight's skepticism of Austrian capital theory (which Eiríksson incidentally ignores) and who also feel that theory should be simple rather than metaphysical, this book will be frustrating. In fairness to Eiríksson, it should be stated that the present reviewer falls into the latter category.

The University of Wisconsin

The Multiplier Theory. By HUGO HEGELAND. (Lund, Sweden: C.W.K. Gleerup. 1954. Pp. x, 261.)

Dr. Hegeland's book is Volume IX in the Lund Social Science Studies, a series by writers connected with the Institutes for Social Sciences, Lund University. It is published in English and has, we are told in the preface, a primary purpose of presenting "a comprehensive analysis of the methodological problems involved in the multiplier theory and in its application to actual processes of income development." It furnishes us with an excellent review and discussion of much of the literature about multiplier theory and, in addition, traces the earliest notions of multiplicative effects as they were discussed before the publication of the 1931 Kahn article. References are made to the writings of Bagehot (1873), N. A. J. L. Johannsen (1903 and 1913), Fr. Johannsen (1928), and other predecessors of Kahn. However, the bulk of the book is concerned with the Keynesian multiplier and the criticisms, adaptations, and applications of the multiplier principle that resulted from the publication of *The General Theory*: that is, the multiplier of income with respect to investment, derived from a consumption function in which consumption is a function of income.

The chapters on lags and leakages provide a generally adequate survey of these discussions and at the same time make clear the differences between the two. There is a useful section on the relation, or lack of relation, between the multiplier and the income velocity of money. Also, brief sections furnish a discussion of the spatial and matrix multiplier concepts and of the possible uses which may be made of these tools.

Unfortunately, the avowed aim of the book seems to lead Hegeland astray. It is his view that the methodological problem in multiplier theory is that the theory is based on faulty assumptions. In his conclusion, he notes that the logical truth of the multiplier theory is self-evident; he does not wish to appear to deny the formal validity of the theory. It is the application of the theory to policy problems that is his concern, and it is here that he feels that we must

question the assumptions. Since it is the empirical truth rather than the logical truth of the proposition that is in question, one would expect that more effort would be devoted to examining the applications of the theory. At one point, Hegeland recognizes the need for such investigation but states that it is beyond the scope of his book. There is, therefore, only a brief section in the concluding chapter in which the results of the application of the multiplier theory in Germany, the United States and Sweden are discussed. The conclusion reached is that only one clear case could be found in which multiplicative effects on income resulted from a period of deficit spending. There is an overabundance of assertions to the effect that confusion exists in the theory between mechanical and real relationships. Part of this problem, he states, arises because of the absence of expectational influences in the original assumptions.

In a footnote comment, Hegeland further asserts that "all multipliers are mere definitions" (p. 158, n. 1). Since he has previously shown that the multiplier theory under discussion is derived from a consumption function which is a behavior relation, it is difficult to reconcile these two points of view. No further explanation of this statement is made except for a reference to Somers who considered the instantaneous multiplier to be a definition. If it were true that all multipliers were simply definitions, there would be no point in discussing either the logic of the theory or the nature of the assumptions. There appears to be little question that the multiplier theory can be stated in the form of a verifiable proposition. In fact, Hegeland has done this.

There are excellent discussions of the political problems concerned with the question of deficit spending and of the statistical and empirical problems involved in concepts such as a marginal propensity to consume for the society as a whole. Had there been more attention centered on the problem of empirical verification and less on the question of the validity of the assumptions, this book would have been a more valuable contribution than it is. It can be recommended highly for its survey, discussion, and synthesis of a large segment of the literature in this area.

ALLAN H. MELTZER

University of California, Los Angeles

Wirtschaftliche Entwicklung und soziale Ordnung. Edited by E. LAGLER and J. MESSNER. (Wien: Verlag Herold. 1952. Pp. 456. $6.00.)

In this work more than thirty economists and social scientists, almost all from Germany and Austria, have joined hands to honor the late Ferdinand Degenfeld-Schonburg of the University of Vienna on the occasion of his seventieth birthday. Most of the articles are written in German, only a few in English and French. The editors were not well advised in choosing a title which is too vague to convey a definite meaning and yet too narrow to do justice to the content of the volume.

Because there is no common denominator among the articles, this review will be confined to a survey of some areas of concentration. There is, for instance, a group of important articles on recent trends in economic and social policies. Most of these are of a highly general character, dealing with such topics as

centralization and decentralization in economic policies (Wilhelm Röpke), problems of the world economy (Adolph Weber), international monetary policies (Joseph Dobretsberger), and social policies (Otto v. Zwiedineck-Südenhorst). Heinrich Niehaus tries to assess the prospects of an agrarian union in Europe. Alfred Müller-Armack, chief adviser to the German Minister of Economics, Ludwig Erhard, interprets the character of the "social market economy," credited with the surprising resurgence of Western Germany after the currency reform of 1948. Somewhat unrelated to this group and the rest of the symposium is a series of essays dealing with the interrelations of law, economics and social organization (Ludwig Adamovich, Alfred Verdross, Hans Schima, and Hans Schmitz).

The overwhelming majority of the other contributions remains within the conventional precincts of economic theory. There are, of course, some departures into the history of economic thought, as in an essay on natural law and economic liberalism (Goetz Briefs, Washington) and a sketch of the earlier stages of economic reasoning (Bernard Pfister). The variety of the other papers is striking. They deal, for instance, with currency depreciation and the terms of trade (Gottfried Haberler, Harvard University), psychological roots of economic dynamics and their significance for value theory (François Perroux, Paris), types of market organization (Alexander Mahr), collective wants (Wilhelm Weber), the public sector of the economy (Anton Tautscher), taxation and socialism (Richard Kerschagl), and welfare economics (Johannes Messner).

While, in the compass of this review, it would be presumptuous to try to convey an impression of the wealth of ideas contained in these papers, an exception should be made on behalf of a defiant article on Keynes, contributed by Hans Mayer of the University of Vienna, generally regarded as the present head of the Austrian School. Both smaller and larger weapons are used in Mayer's frontal attack. Let us first mention his objection to the definition of the labor unit by which, according to Keynes, employment is to be measured. The conversion of an hour of special labor into hours of ordinary labor appears to Mayer not only as a naïve oversimplification, but also as a resurrection of a long-since disproved part of the Marxian labor value theory. In the same context he questions the reality of the alleged concentration of the workers on nominal wages. Although Keynes did not take pains to support his argument by empirical data, Mayer refers to the interest of labor unions in adjusting their wages to index numbers as indicating the opposite attitude. Keynes' basic contention that underemployment may be coincidental with a stage of equilibrium is rejected as too general. It could never happen if wages were flexible. The "fundamental psychological law"—Mayer believes—was neither fundamental nor even a general psychological law. Its validity depended upon the level of incomes and the structure of income distribution. The incomes should considerably exceed the minimum of existence. Of another related element of the Keynesian model, Mayer suggests that it was inconsistent with an essential principle of the *General Theory.* How could the consumption function be assumed to be stable in the short run if, in general, all economic quantities varied with a change in income? Consequently the consumption function should

not be regarded as a pillar of the Keynesian system. It was only the "illusion of a pillar" (p. 48). With the same firmness other Keynesian positions are challenged, for instance, the concentration on full employment instead of on the maximization of satisfaction, the scant attention given to dynamic factors, the predilection for monetary analysis, and, of course, the predominance of the aggregative approach.

In Mayer's view those deficiencies loom too large to be offset by some valuable clarifications of more special problems, particularly in the fields of money and credit. Nor should Keynes be praised as the originator of revolutionary notions. The *General Theory* was not a system; it was not even a theory in the customary sense. Thus Mayer cheerfully subscribes to Leontief's cynical remark that Keynes "seemed to press . . . for reconstruction of the whole foundation in order to mend a leaky roof."

FRITZ KARL MANN

Washington, D.C.

Value, Capital and Rent By K. WICKSELL. Translated by S. H. FROWEIN. (New York: Rinehart. London: G. Allen and Unwin Ltd. 1954. Pp. 180. $3.50.)

The recent appearance of this translation of Wicksell's first book, *Über Wert, Kapital und Rente* (Jena, 1893), is both timely and long overdue. Its timeliness arises from the fact that it contains a penetrating evaluation of Leon Walras' *Elements of Pure Economics*,[1] which also first became available in English a short time ago in Jaffé's remarkable translation. The early exhaustion of the reprinted German edition of Wicksell's work shortly after it was issued in 1933 by the London School of Economics is, however, clear proof that there has been an unfilled demand for the present translation for many years.

To scholars and specialists, *Value, Capital and Rent* is of interest chiefly from the standpoint of history of economic thought and more particularly because of the contribution Wicksell made to the marginal productivity theory of distribution. For one thing, his treatment of the role of time in the theories of value and of distribution was original and unique for its period. Further, it is notable that in this work he was the first theoretician to achieve a synthesis between the Walrasian and the Austrian types of economic analysis.

For contemporary students this treatise is likely to be of considerable pedagogical value as an introduction to comparative static equilibrium analysis. It should prove especially instructive to the theoretically inclined, for here they are given more than just a glimpse, at the level of the elementary calculus,

[1] Wicksell's early criticism of Walras, particularly of his concept of capital as propounded in the second edition of *Elements of Pure Economics*, is expressed in *Value, Capital and Rent*, pp. 18-21, pp 92 ff, and pp. 164 ff. In his later writings Wicksell modified his position on the Walrasian theory of interest and capital. On this point see particularly pages 236-38 and pages 225-27 in his article "Professor Cassel's System of Economics," which is appended to the English translation of Wicksell's *Lectures on Political Economy*, Vol. I (New York, 1934). For comments on some of Wicksell's criticisms of Walras, see Jaffé's "Translator's Notes" in Leon Walras, *Elements of Pure Economics* (Homewood, Ill., 1954), pp. 510 ff.

of how effectively mathematics can be applied in economic analysis. As a painless introduction to "mathematical economics," this work has, so far as this reviewer is aware, no equal in the English language, with the possible exception of E. H. Phelps Brown's *The Framework of the Pricing System.* The latter, however, deals with equilibrium analysis in a less complete manner than does Wicksell and further, Phelps Brown reduces, not always without difficulty, all demonstrations to arithmetic.

This translation by Frowein is, on the whole, excellent and true both to the spirit and the letter of the original. However, it is unfortunate that he interpreted the word *Rente* in the title as "Rent" instead of as "Interest." The German word *Rente* has no direct equivalent in English usage, except possibly something as clumsy as "property income." On the other hand, our term "rent" is too closely associated with the Ricardian concept of differential land rent to serve happily in the title of a work which devotes far less attention to the theory of rent than it does to the theory of interest. For the foregoing reasons this reviewer believes a more representative title for the translation would have been *Value, Capital and Interest.*

Shackle's "Foreword" to the English version of this work attempts to establish a direct link between the interest theory expressed in *Value, Capital and Rent* and the cumulative process analysis of Wicksell's later monetary writings, as well as a direct connection between the latter and the monetary analyses of Keynes and of Hayek, which are treated as complementary to one another. This probably stretches one or more points too far. At least in so far as Wicksell was concerned, his theory of capital and interest underwent several changes over the years. The link between the interest theory of the present work and the analysis of variations in the natural rate versus the market rate of interest in *Interest and Prices* (New York, 1936) and in his *Lectures on Political Economy*, Vol. II (New York, 1935) is, to say the least, not very direct. This is due to the fact that he gradually abandoned the period of production concept of capital featured here for other and more fruitful conceptions.[2] As it is, Shackle's essay would probably be a more appropriate foreword for Wicksell's *Interest and Prices*, for which it was not intended, than it is for *Value, Capital and Rent.*

University of California, Riverside

Economic History: National Economies; Economic Development

From Mine to Market: The History of Coal Transportation on the Norfolk and Western Railway. By JOSEPH T. LAMBIE. (New York: New York University Press. 1954. Pp. xviii, 380. $6.00.)

This interesting volume, the third in the Business History Series of New York University, is a very creditable job. In fifteen well-written chapters Professor Lambie has traced the development of one of the important

[2] Concerning the transformation of Wicksell's capital analysis, see, for instance, the present writer's article, "Knut Wicksell—A Centennial Evaluation," *Am. Econ. Rev.*, Dec. 1951, XLI, 844-48, 850-52, 856-57.

Pocahontas railroads from its origins in the mid-nineteenth century to the present. The major emphasis is on the important events of the late nineteenth and twentieth centuries. This is, however, no noneconomic chronicle of the glamour and achievements of railroading, nor is it a glorification of the company and its management. Rather economists will here find a sober and critical discussion of the economics of railway policy.

Lambie devotes major attention to those matters which are of major concern to transportation economists, such as rate structures, pooling, the relations between coal operators and carriers, rate warfare, the problem of the allocation of the car supply among mines, differentials in the rates from the coal fields to the various ports, and the maneuvers of the major coal carriers, the Norfolk & Western, the Chesapeake & Ohio, the Virginian, and the Pennsylvania to secure profitable coal traffic. He has shown a sure grasp of the major factors in the economic survival of the railroad.

The author has made extensive use of the archives of the railway, but he has carefully balanced this material with that from the many Interstate Commerce Commission cases on the coal trade and the coal rate adjustments as well as other sources on the tidewater coal business generally. The result is a balanced and useful discussion of the rise of this important branch of American traffic. Economic historians will also find that the author has filled a number of gaps in the economic history of the East, while the new breed of specialist, the business historian, will find much of interest with respect to business organization and policy.

John G. B. Hutchins

Cornell University

Soviet National Income and Product, 1940-1948. By Abram Bergson and Hans Heymann, Jr. A Research Study by the Rand Corporation. (New York: Columbia University Press. 1954. Pp. xii, 249. $5.00.)

Soviet National Income and Product in 1928. By Oleg Hoeffding. A Research Study by the Rand Corporation. (New York: Columbia University Press. 1954. Pp. 156. $3.75.)

These two books follow the methodology established by Bergson in *Soviet National Income and Product in 1937* (Columbia University Press, 1953). Altogether Bergson and his associates have now presented comparable cross-sectional national income accounts for the Soviet Union for five important years: the eve of the Plan Era; 1937, the terminal year of the second five-year plan and a turning point in many respects; the last full prewar year, colored by intense military preparations; 1944, the peak of the war years; and 1948, a year witnessing considerable progress in reconstruction and in the "normalization" of economic life after the war. Thus the trilogy is of the greatest significance for our understanding of the structure of the Soviet economy at various crucial points in its development, and of changes therein over time. The authors have not (as yet) deflated their results for the intervening price movements.

The essence of Bergson's methodology is the conversion of actual ruble values, in themselves of doubtful analytical meaningfulness, to "adjusted

ruble" values in conformance with a theoretical "Adjusted Factor Cost Standard" (AFCS), so as to permit the measurement of national product and its components in terms of "real" resource cost. The authors display much insight, statistical skill, and theoretical acumen to this end. But the inadequacies of the underlying data force them to restrict factor costs almost entirely to the return to labor services and the accounting profits of enterprises (chiefly state-owned), and largely to omit interest and economic rent. Moreover, the rationale of treating the accounting profits as a "real" factor cost is—as the authors agree—a debatable one. In a side calculation, Bergson and Heymann attempt to appraise the probable effects of these deviations from the AFCS on the shares of defense and investment in total outlay, 1937-1948 (pp. 75 ff.). The resulting corrections are at times appreciable, though not major.

Even such a large and "simple" factor return as the earnings of hired labor falls short of the requirements of the AFCS upon closer scrutiny. The chief theoretical difficulty here, as Bergson and Heymann point out, is the intrusion of stringent manpower controls since 1940, throwing doubt on the correspondence between wage and salary differentials and differences in "real" costs. Obviously, the authors can do no more than explain the difficulty and try to live with it.

The trilogy bears eloquent witness to the drying up of quantitative information on the Soviet economy over the twenty-year span embraced by it. Hoeffding still has the benefit of voluminous and high-quality statistics for the late 'twenties, and at times is even embarrassed by the riches of his sources. This ample fountain becomes a trickle by 1937 and 1940, and all but gives out for 1944 and 1948. To compile their accounts for the last two years, Bergson and Heymann can rely on only scattered and very fragmentary data, and thus have to resort continually to inter- and extrapolation, indirect evidence, bold estimation, and outright "educated guessing." The result for these years at least in part depends on their *Gestalt*-like perception of the Soviet economy, and to this extent will undoubtedly diverge in detail, if not always in major outline, from the images obtained by other students in the field. But considering that they take pains to spell out their guesses and assumptions, the present reviewer finds in this not so much a cause for criticism as an occasion for commending the authors' courage.

The conceptual and statistical handicaps are compounded perhaps most seriously in the valuation of consumption in kind, chiefly food consumed within the same peasant household or the same collective farm. This the authors express at current average realized farm prices, except for 1944, when they use 1940 average prices. Perhaps indicative of the inherent difficulty of the problem is that Bergson's 1937 study has already been criticized for attributing both too high and too low a value to this component. In this regard one must be careful to eschew criteria that are extraneous to his approach. The AFCS aims only at making ruble values express "real" costs; hence, factors of comparable productivity ought to receive approximately the same valuation. The AFCS does *not* attempt to express by means of ruble values the relative standards of living of owners of the factors, as some of Bergson's critics seem to have implicitly assumed. Nevertheless, valuation of food consumption

in kind at average realized farm prices may not be the procedure most consistent with the AFCS, and, as this reviewer has suggested elsewhere, may have led Bergson to understate the contribution of peasant producers in 1937 (and hence also the relative shares of agriculture and of consumption in the respective totals), if the earning rate of comparable *wage* labor is taken as a yardstick. On the other hand, this understatement (if any) may be much smaller for 1948, not because peasants fared better relative to urban workers in that year than in 1937—they fared much worse—but because agricultural *wage* labor also seems to have earned relatively very poorly in postwar years, judging by some scattered indications in Soviet literature. It should be noted that the authors are very much concerned with the valuation of returns to peasant labor, and both Bergson-Heymann (pp. 58 ff. and 78) and Hoeffding (pp. 63 ff.) offer interesting alternative computations.

The statistical results of these studies will undoubtedly provide food for thought to economists and other social scientists for many years to come. Consider the finding that the rate of gross investment out of gross national product (in terms of "adjusted rubles") was already as high (23 per cent) on the eve of the first five-year plan as in 1937, and almost as high as in 1948. (If some of the alternative computations are accepted, more of an upward trend is indicated.) But the consumption of households fell, from 66 per cent in 1928, to 56 per cent in 1937, and to 45 per cent in 1948. The decline in the share of consumption was almost entirely absorbed by rising shares of defense, security forces, and communal services. At this juncture the reader is welcome to speculate about the impact of political events—past, present, and prospective—on the course of Soviet economic development.

Another interesting finding is that even at the very height of the second world war, and at a time of extreme consumer privation, the Soviet Union was able and willing to maintain a rate of gross investment of 13.5 per cent. True, some of it was undoubtedly urgent reconstruction in the liberated areas, and some was greatly expedited by lend-lease and other allied help. Moreover, the figure may contain an upward bias in that much of this construction was undertaken with lavish resort to monetary incentives. Still, the fact bears attention. The trilogy thus abounds in significant and challenging statistical results. The authors offer only a modicum of interpretation of their findings; the rest is up to the reader, and, one hopes, to the authors' own pens in the future. Even so, there is no doubt that the work ranks among the most important contributions to western inquiry into the Soviet economy.

GREGORY GROSSMAN

University of California, Berkeley

The Prospects for Communist China. By W. W. ROSTOW in collaboration with RICHARD W. HATCH, FRANK A. KIERMAN, JR., and ALEXANDER ECKSTEIN. (Published jointly by the Technology Press, Boston, and John Wiley & Sons, New York. 1954. Pp. xx, 379. $5.00).

This is an interpretative essay on the prospects of success or failure of the Communist regime in the China mainland. The book is divided into six parts, dealing successively with (1) the struggle for power up to 1949, (2) the evolu-

tion of Communist policy, (3) the regime and the people in the light of Chinese history and in terms of their current aspirations and reactions, (4) Sino-Soviet relations, (5) the Chinese economy, and (6) the prospects of the regime. Parts 3 and 5 are chiefly the products of the associates, and Rostow is responsible not only for the other four parts but also for the formulation of a unified view in interpretation. While interpretation is by nature subject to controversy, I find that his judgment on the whole is remarkably balanced and sound. Rostow need not feel apologetic about "this intrusion by an outsider into the field of China studies" (p. viii), for the book is as significant to students of Communist China as to those interested in the economic development of underdeveloped countries.

The underlying theme of the book is that the Communist regime is primarily concerned with maximization of its political and military power in China, within the Communist bloc, and vis-à-vis the external world. The economic development program, with its emphasis on heavy industry and transport at the expense of agriculture and consumers' welfare, is calculated to be a vital measure to attain this objective; and it is upon the outcome of this program that the prospects of the regime will largely depend. Evaluation of the program appears as Part 5 in the book and is chiefly the work of Alexander Eckstein. The first three years of the Communist regime (1950-52) were a period of general economic recovery, price stabilization, and institutional reorganization, thus preparing the ground for sustained industrialization under the first five-year plan to start in 1953. In view of the Communist propaganda on the rapidity of recovery to the prewar peak during this period, it is interesting to find in the analysis that excepting 1949, a year of acute drought, Chinese agriculture had recovered steadily since 1945 and the regaining of the 1936 level by 1952 was a continuation of the same trend. According to the absolute figures on production given by Chou En Lai of the regime in September 1954, which came too late for the author to use, it is also clear that industrial production in 1949 was not as low as he estimated (p. 239)—*e.g.*, there was a 20 per cent underestimate of coal and electric power production. The institutional reorganization is well presented, though reference should have been made to the important Communist technique whereby private enterprises have been reduced to relying almost entirely upon the orders of state enterprises. It has been officially reported that 86.4 per cent of the production of all the large private firms in eight biggest cities was for state enterprises by the first quarter of 1953.

The target of the plan, if Chou's figures for 1954 are to be trusted (and they seem reasonable), is to bring the industrial sector close to the Soviet 1932 level. This, if attained, would be a significant achievement. The study finds that "this rate of growth would not seem to lie beyond the resource capacities of the Chinese Communist Economy" (p. 277). This conclusion is reached with a number of assumptions, the most important of which are (1) that 12 per cent of the gross national product (a rate estimated for 1952)—and a progressively higher rate as time goes on—is for gross domestic investment in the modern sector, this not including nonmonetary investment in the rural sector, (2) that 20 per cent of the industrial capital formation is derived from

exports mainly of agricultural and mineral products, and (3) that a minimum increase of 13 per cent in agricultural output from 1952 to 1957 is necessary to meet the export requirements and the consumers' demand of a growing population and urbanization, provided (4) there is Soviet economic assistance amounting to $100 million for the whole period. Shortly after the study was made, there came an official announcement of $130 million of Soviet economic aid. The key to the success of the plan is then held in agriculture. According to official reports, there was an annual increase of 3 per cent in food grains for 1953 and 1954; nevertheless the value of agricultural production (presumably at 1952 prices) had risen only 1.5 per cent for 1953 when the cultivated area damaged by floods and drought was but one-half as large as the area damaged in 1954. This perhaps explains the sudden rate of agricultural collectivization last year, for which the regime was unexpectedly called upon by these circumstances to realize: the number of producers' cooperatives organized by the end of the year was eleven times the target set for the twelve months at the beginning of the year, now covering about one-tenth of the total number of rural households. Whether agricultural production will be increased by this device remains to be seen. There is at least strong supporting evidence that "the success of Peking's First Five Year Plan is not assured" (p. 218).

On very much the same assumptions the author proceeds to construct an interesting model of Chinese self-sustained economic development from 1952 to 1962. It is found that over the decade the gross national product would be increased by some 37 per cent and per capita income by 8 per cent. However, the statistical information released by the regime in the last quarter of 1954 calls for a radical revision of these estimates.

University of California, Berkeley

The Economic Development of Japan. By WILLIAM W. LOCKWOOD. (Princeton: Princeton University Press. 1954. Pp. ix, 603. $10.00.)

Professor Lockwood's monumental study covers the growth and structural change in Japan's economy from 1868 to 1938. His purposes originally were twofold: (1) "to show the importance to Japan of the international order which her militarists had done so much to destroy, and which would have to be recreated in its essentials if she were again to prosper," and (2) to challenge a prevalent notion "that Japan's economic development since the Meiji Restoration had been confined mainly within the sphere of foreign trade and factory industry, that its benefits had been largely drained away in imperialist wars and zaibatsu profits." As his researches progressed over a decade, however, his task broadened into a study of the whole process of Japan's economic growth from 1868 to 1938.

As a case study in economic development this volume will interest many economists, even though they have no particular concern with Japanese problems. It is the record of one of the most remarkable transformations in economic history. Within the space of three generations Japan emerged from national poverty and seclusion to become one of the leading industrial powers. How was it done? What were the key elements in the transformation? What

are the lessons for nations still on the threshold of economic development?

Primary production (food and raw materials) in Japan increased fourfold between 1873 and 1911. This growth clearly outran the 40 per cent increase in population over the same period. It provided a major share of the savings and tax revenues which financed the industrial and military expansion of the period. Nor did growth cease after 1914. From 1910-14 to 1930-34, there was a 45 per cent increase in food production and a 75 per cent gain in output of raw materials. This compares with a 34 per cent rise in population over the same period. More spectacular was the rise in manufacturing activity. In the quarter-century from 1905-9 to 1930-34, there was a fourfold advance. From the turn of the century, for four decades, manufacturing advanced at an average annual rate of almost 7.5 per cent. Greatest relative gains came during the first world war and at the time of the world depression, in 1931-35.

The best criterion of expansion, however, is the over-all growth in net national product. Based on a comprehensive inquiry by Yuzo Yamada of Hitotsubashi University (*Nihon Kokumin Shotoku Suikei Shiryō*, Tokyo, 1951) Lockwood concludes that the aggregate increase was fourfold from 1885 to 1935. This is an annual rate of nearly 3.3 per cent. According to Yamada's figures real income produced within the country nearly doubled in the quarter-century before 1910. It then doubled again during the first world war and the postwar decade. In the boom of the 'thirties the index rose another 50 per cent. The population of the country rose from 39 million in 1885 to 69 million in 1935. Yamada's figures therefore imply a per capita increase of 150-200 per cent in net output.

Although only part of the aggregate growth in income produced was actually available for raising living standards, the rise in consumption levels was substantial. For example, real wages rose 33 per cent between 1897 and 1914 and 65 per cent over the next quarter of a century. The average industrial worker in Japan was able to buy at least twice as much with his daily earnings in 1937 as he could in 1897.

How did all this come about? Lockwood takes pains to minimize the role of the state. ". . . a study of the whole process of economic growth in modern Japan leads to the conviction that the real drive and momentum lay in large measure outside the realm of national political ambition and State activity. At most the latter only accelerated a process of industrialization which was latent in the whole conjuncture of forces at work." It was, in Lockwood's view, the unleashing of individual ambition and private enterprise at a very favorable point in history (world trade expanding, prices rising, etc.) that brought about Japan's growth.

He doubts that the process can be repeated again in other Asian countries. "Many of the peoples of Asia are developing a set of social expectations and immediate demands such that they will probably be unwilling to tolerate the great inequalities of private property and income so patiently borne by the Japanese." Furthermore he sees little evidence that the well-to-do class elsewhere in Asia "is disposed so largely as it was in prewar Japan to save and invest." He warns that the lesson of Japan indicates that unless population growth can be held in check, the mere increase in numbers will absorb much of

the gains of development, and "unless political institutions can be created to harness productive power to welfare goals, still more of the gain may be dissipated in war and conquest."

College of The City of New York

Britain and the U.S.A. in the Caribbean: A Comparative Study in Methods of Development. By MARY PROUDFOOT. (New York: Praeger, 1954. Pp. xxi, 434. $8.50.)

Comparing the methods employed and the results achieved by Britain and the United States in one area where both have had a certain responsibility for nonself-governing people seems at first an intriguing idea. Perhaps by setting one policy off against the other the strengths or weaknesses of both might appear. It was with this possibility in mind that Mrs. Proudfoot set out on her research. Some six years later she comes to the publication of her findings not at all sure that anything of significance has turned up. The effort has some of the irrelevance of comparing apples and horses.

The British are an old and responsible colonial power, organized to carry the obligations of supervisorship. The United States has wanted to pretend not to possess colonies even though temporarily it might have substantial population and areas attached to itself. The British methods are only suitable to a highly professional bureaucracy with a permanent policy and a fixed governmental setting. They could not possibly be transferred to the United States which is without a professional service, has only a rudimentary governmental office to set over against the mighty Colonial Office in London, and has legislators who only infrequently show a sense of responsibility toward subject peoples—especially when the interests of their constituents are affected.

But academic researchers do not give up easily. Mrs. Proudfoot's is one of the series of Colonial and Comparative Studies so ably edited by Marjorie Perham of Nuffield College, Oxford. And she makes the unlikely comparison yield some worth-while results. These are not so much methods which either nation could borrow wholesale from the other as they are materials for self-examination. In the vast undertaking represented by the transformation of a colonial empire into a commonwealth, Britain cannot afford to overlook any experiment or suggestion. And Americans are reminded, if they do not already know, about a chapter of incredible irresponsibilities which may possibly have lessons for the future. Perhaps, after all, the seemingly incongruous developments may yield some returns of a practical sort.

One thing is certain. The United States will never again willingly undertake to administer a conquered people. And the reasons why this is so, and ought to be so, are amply set forth here in many careful pages. These recite the deficiencies of administration, the whimsicality of policy, and the bursts of expensive generosity which have marked the Puerto Rican and Virgin Islands enterprises. And it is made clear that these go back to the nature of our institutions. Informed students have known all this, of course, for a long time. There have been numerous studies, particularly of Puerto Rico, which could lead to no other conclusion. It may even be that self-examination on the part

of Congressmen may have played a considerable part in the decision to establish the *Estado Libre Associado* or Commonwealth, which has now existed for six years. It can be taken as a confession of inherent disability. For American students Mrs. Proudfoot's study covers familiar ground.

British students very likely have no more to learn. The researches of the past decade have been numerous and competent. But it is worth while to reinforce them with a pointed reminder concerning mistakes which, in spite of a great bureaucracy, a responsible attitude, and well-known facts, have been profound.

The truth of the matter is—though what lesson there is in it, I should hesitate to conclude—that the two creative and reconstructive ideas which have proved to be valuable have come from the Americans and not from the British. These have been the Estado Libre Associado and the development program, both exemplified in the Puerto Rico of the last decade, the one political, the other economic, and each complementing the other.

The British are persisting in fostering a dominion in the West Indies after the pattern of the others so successfully developed elsewhere. But Jamaica and Trinidad, the two considerable colonies—both in population and resources—are separated by 1200 miles of open sea. Stretching in a north-bending arc, Barbados, the Windwards, the Leewards, and the British Virgins have, among them, so scarce a population, and so little commerce with one another, as to ensure a serious divisiveness. It would surely have been more sensible to have followed the Puerto Rican pattern and set up several associated states. Now it is too late.

The British have had a development program since before the war. It resulted from the recommendations of the Moyne Commission of 1938. From the first, however, it concentrated on welfare rather than productive development. The result was a series of fine educational, health and allied institutions beyond the means of the local governments to support, although the policy was not to outrun local resources. In Puerto Rico a sharply contrasting concentration on productive facilities has set in motion an upward spiral so decisive that the island has become a kind of pilot plant for induced economic development among all underdeveloped peoples.

Mrs. Proudfoot could hardly be expected to draw so sharp a conclusion which perhaps I may exaggerate. As a result, however, of not doing it, she is inhibited in accounting for the rapid rise of well-being in Puerto Rico and the relative slowness of development in the British colonies.

I should not expect her to agree that dominion is an impracticable objective for the West Indies. It is by now an accepted British policy, however reluctantly the more prosperous islands approach union with the less prosperous ones. It must be said, however, that there are hints concerning the value of the Puerto Rican example. There is an unacknowledged resemblance to it in the Jamaican development scheme and, so far as they could, others seem also to have followed. But the inherent difficulties make the same approach inexpedient.

It seems to me important to say that one item of American methodology of utmost significance is not fully uncovered by Mrs. Proudfoot, careful as

her surveys have been. The Puerto Rican success is very largely owed, in my opinion, to the intimate connections between various government departments and the corresponding insular departments which have been possible without centralized intervention. Life-giving technology and grants-in-aid from the federal complex flow through Puerto Rico just as though she was one of the sisterhood of states. This is true in agriculture, health, education, public roads, hospitals—all the various state-aid programs. There is no colonial office through which assistance must be routed—and, it might be said, no State Department either. The one has prevented development in the British dependencies; the other has gone a long way to nullify efforts to assist Central and South American countries.

If there is a "secret" in this matter of induced development I feel certain this is it. But, of course, it is not available for British emulation.

Mrs. Proudfoot's book is in sequence rather with Paul Blanshard's *Democracy and Empire in the Caribbean* (New York, 1946) than with such more specialized studies as H. S. Perloff's *Puerto Rico's Economic Future* (Chicago, 1952) and others of a similar sort. The comparative effort may not be very rewarding, but the information is reliable and the observations on the whole are well considered.

REXFORD G. TUGWELL

University of Chicago

Economic Problems of Underdeveloped Countries in Asia. Edited by B. K. MADAN. (Bombay: Oxford University Press. 1953. Pp. iv, 290. $3.30.)

This volume presents a sample of professional Asian opinion regarding development policy. Most of the contributors are economists, twelve from South and South East Asia, one from the Middle East, and three Westerners now living and working in the East. Their papers are grouped in three sections, which might be titled: the role of foreign capital and technical assistance (6 chapters); surveys of economic development in particular Asian countries (9 chapters); and proposals for an international development authority (1 chapter).

The purposes of the Indian Council of World Affairs in publishing these articles (which first appeared in *India Quarterly*) were "bringing the facts up to date" and "offering detailed and constructive suggestions on the subject." Since the material upon which the volume is based is now three years old, those chapters which concentrate on the first objective miss their mark. They demonstrate, instead, that attempts to give capsule descriptions of entire national development programs make dry and insignificant reading. Fortunately, however, those authors who have ventured policy suggestions have not confined themselves to "detailed . . . suggestions," but have dealt with some of the larger issues faced in common by most of the underdeveloped countries.

B. K. Madan (India) poses the problem of financing basic development projects which have negligible or low yields with foreign grants or cheap loans. Most of this aid must come from a single country, the United States, which leads to bilateral agreements. However, Madan wants an international agency as intermediary. V.K.R.V. Rao (India) reviews the development of thought in

the United Nations and program proposals to deal with this problem—including his own suggestion for an International Development Authority. Acceptance has grown for the idea (and practice) of intergovernmental capital grants as a supplement to interest-bearing governmental, private, and International Bank loans. But Rao's desire for complete separation of grants from actual or implied political commitments by establishing an international granting agency has gone unfulfilled. Nevertheless, Rao's views make good reading alongside current discussions of United States foreign aid.

Several contributors consider the role of private capital in development. Maurice Zinken (Lever Brothers—India) argues that the developing country must embrace private saving as a virtue, acclaim the entrepreneur, and encourage its citizens to strive for material gain—types of behavior which are notably lacking. D. R. Gadgil (India) believes that too much reliance on private capital formation is exactly what is wrong with India's present approach to development. India's official planners might not agree with Gadgil that they have given top priority to public expenditures on agriculture and transport in order to avoid interference with private business in the industrial sector (pp. 83-84). Other reasons can be given. Nevertheless, Gadgil argues forcefully that the Indian government should use stronger measures to increase the flow of savings into its own hands and employ these resources primarily for the development of basic industry.

There is nothing new in the issues or arguments, but for those who would like to know where some influential Asians stand, the book is worth examining.

FREDERIC C. SHORTER

University of California at Los Angeles

West African Trade—A Study of Competition, Oligopoly, and Monopoly in a Changing Economy. By P. T. BAUER. (New York: Cambridge University Press. 1954. Pp. xvi, 450. $10.00.)

Mr. Bauer's work represents six years of research and writing sponsored by the Colonial Office and financed by Colonial Development and Welfare funds. It is unquestionably an able and comprehensive study of the external trade of the Gold Coast and Nigeria. To this reviewer, its value is unfortunately seriously qualified by the author's polemics against practically all interventionist policy and implicitly against the very notion of development planning.

Separate sections describe and analyze the import and export trades, their monopolistic elements, marketing reform policies, and the important development of statutory marketing of principal export crops. Apparently the original project was to focus upon the activities of the few large firms which have dominated the commerce of West Africa and particularly upon the huge Lever Brothers combine, United Africa Co. Bauer clearly shows the basic oligopolistic and often restrictionist character of the markets, but the greater part of the book, notwithstanding its official sponsorship, is an attack upon *government* policies.

The work focuses principally upon two matters: the role of administrative restriction in perpetuating concentrated markets, and the role of the statutory marketing boards in their alleged effects upon economic development. West

African commerce tends naturally to monopoly because of the special capital and experience requirements. But government policy has served rather to reinforce this tendency and to inhibit potential competition. In Bauer's eyes, true protection for Africans lies only in the promotion of more competition and the reversal of interventionist policy designed to protect African producers, traders, and consumers. The complex of trade, exchange, and price controls; restrictions upon immigration and European land purchase, and statutory marketing serve only to deter possible new entry and investment.

Bauer apparently fails to appreciate that policy objectives other than the vigorous promotion of European commerce must be considered. The history of such areas fails to show how the economic development and welfare of *Africans* can be expected under such a policy. It is more likely that it would serve to perpetuate the typical colonial patterns of monoculture, economic dependency, and low productivity. It would certainly not help provide the basic *public* investment which is so urgently needed to change the existing economic structure.

In any case, Bauer's prescription has little relevance to the development programs of the present popular and largely self-governing nationalist administrations. These have ambitious public investment schemes under way, to which most of the controls are intimately related. Moreover, there are articulate African trading interests to be reckoned with politically.

His favorite target is statutory marketing, and his criticism is merciless and consistent. The boards originated as wartime improvisations. They were retained as a reform of the chaotic prewar pattern, which was characterized by buying rings, a bewildering array of middlemen and moneylenders, and extensive producer indebtedness. The boards have fixed annual buying prices (of cocoa, palm products, and groundnuts mainly) and have accumulated large reserves. These have neutralized inflationary pressures of high export prices and have enabled a higher rate of public development expenditure. Bauer condemns the boards on the following counts: (1) They cut the link between the peasants and the world market; (2) they exact a high rate of forced saving from the producer in addition to a high tax rate; (3) by bulk-sales agreements they have sometimes realized less than the world price; (4) they inhibit private trading interests; (5) they have not defined stabilization precisely—consequently, price-volume relationships have sometimes *destabilized* incomes; (6) the accumulated reserves inhibit the development of private savings and investment; (7) steeply graduated export duties, made easier by centralized marketing, plus the anti-inflationary accumulated reserves, have made possible large-scale public development investments, the economic yield of which is, in his opinion, typically low; (8) low producer prices have restricted cocoa-planting expansion, driving world prices to record heights.

All but the last point are largely valid but essentially irrelevant. They make sense only on the assumption that domestic price stability, planned public investment, and the rational use of agricultural resources are secondary or even pernicious objectives. But domestic food supply is quite inelastic. It will remain so until fundamental agricultural research can prescribe a secure

substitute for the system of shifting cultivation. If producer prices, especially of cocoa, were not restricted, domestic food prices would skyrocket. Thanks to the boards' policies, this has been avoided, enabling development plans to proceed under more orderly circumstances. The reserves of course are still available for future price maintenance.

As for the effect upon cocoa supplies, Bauer neglects the facts that new plantings take seven years to produce, that there is little more good cocoa land, that much new planting nevertheless has been continually undertaken, and that stability of price is a more crucial incentive. In any case, indiscriminate extension of cocoa acreage could very well be disastrous to a precarious vegetation-soil-rainfall complex. Increased output must be sought in higher yields per acre (the boards finance the needed research), and in disease control and rehabilitation (the high costs of which the boards are meeting). Postwar prices are due to short supply, which has lagged because of disease and because planting was discouraged under the unpopular prewar "free" marketing arrangements. The boards cannot be held responsible for the price explosion.

Upon producer price control depend the development plans, the pending Volta River Project, the maintenance of political stability, and the possibilities of transforming a cocoa economy. Usually when such countries receive export-price windfalls, higher incomes and exchange earnings are frittered away, and disorderly inflation ensues. The countries are then castigated by Western economists as irresponsible. African leaders in the Gold Coast and Nigeria are, however, following another path, avoiding inflation, capturing and plowing back such windfalls into basic investment. For this Bauer accuses them of political opportunism and of exploiting their own voters. His strictures are consistent with familiar "free market" dogma, and consequently the many arguments in favor of the boards and their policies, in their specifically West African context, he dismisses. But these countries have different objectives from those of the unplanned economy of Bauer's dreams.

The boards and their policies have been retained by the new African administrations. They are politically supported by the populace, despite some local grumbling—often based, as in Ashanti, upon other political grounds. Bauer attributes this political acceptance to the demagoguery of politicians appealing to the "political" urban elements. But Prime Minister Nkrumah has twice overwhelmingly swept the rural Gold Coast cocoa areas in free elections.

To Bauer, economic development means whatever investment pattern emerges in the private sector of a "free" economy. But West African development requires enormous integrated investment scarcely imaginable under private auspices. Given the development objective, there are few alternatives to the boards' policies.

These criticisms aside, the book is a masterful organization and exposition of new and important material. The author should be especially commended for the impressive selection of statistical information.

Statistics and Econometrics

Economic Activity Analysis. Edited by OSKAR MORGENSTERN. (New York: John Wiley & Sons. London: Chapman & Hall, Ltd. 1954. Pp. xviii, 554. $6.75.)

This volume contains thirteen papers written under the auspices of the Economics Research Project at Princeton University, and financed by the Office of Naval Research. The papers are by J. B. Balderston, C. Bernstein, R. Bott, O. Eckstein, J. P. Mayberry, K. Menger, C. P. Modlin, Jr., O. Morgenstern, G. Rosenbluth, T. M. Whitin, Y. K. Wong, and M. A. Woodbury. The volume as a whole must be classified as mathematical economics, although there is one essay (by Morgenstern) which is not mathematical, and a couple of essays (in Part II) which are not economics.

Part I, with four papers, is concerned with input-output economics. The mathematical level is usually that of most papers in this field, and the papers should be of considerable general interest. The opening paper discusses briefly four models of general economic equilibrium, while the second deals in more detail with the Leontief input-output model. The last two papers are concerned with specific problems in input-output analysis, and will be discussed further below.

Part II, with seven papers, is entitled the "Mathematical Properties of Linear Economic Systems," and employs mathematics well beyond the reach of all but a very few economists. Furthermore, most of the problems considered are not interesting to economists, since they are primarily mathematical. The papers apparently develop new theorems about the mathematical properties of linear systems (although this reviewer is incompetent to assess the mathematical contribution), and these theorems should have implications for their economic properties. The fact that few of these economic properties have been developed does not mean that the work will not be useful to economics. Mathematical understanding of these systems, to which these papers contribute, must necessarily precede economic understanding.

Part III contains two papers. Menger discusses some of the logical implications of the laws of return, and Morgenstern discusses the future of "Experiment and Large Scale Computation in Economics."

The general economist will probably be most interested in Menger's paper on the laws of return. This is an outstanding example of how mathematics (logic) can and should be used in economics, and should be required reading for all graduate students who have taken freshman calculus. Menger notes that economists have made the following three statements about the laws of return: *A*. The output of a given piece of land cannot be increased indefinitely by the application of more labor, but reaches a maximum. *B*. An increase in the quantity of labor applied to a piece of land will increase the output of the land by a smaller percentage than the (per cent) increase in the quantity of labor, provided that the initial quantity of labor is large enough. *C*. A given increase in the quantity of labor applied to a piece of land will result in a smaller increase in output, the larger the initial quantity of labor, again provided that the initial quantity of labor is large enough.

Economists have, however, not been satisfied only to assert each of these propositions as true statements about the real world. They have further asserted: (1) that statements *B* and *C* are equivalent, *i.e.*, that *B* implies *C* and vice versa, and (2) that *A* implies both *B* and *C*. Note that these propositions have nothing to do with the real world: their truth does not depend upon any observable phenomena, but only upon logic. Thus it can be—and Menger demonstrates that it is—that statements (1) and (2) are false even though *A*, *B*, and *C* are all true. The lesson that Menger brings home is that we should use the tools of logic if we want to make logical statements.

Specialists in input-output will probably be most interested in the papers in Part I on the aggregation problem, and the problem of allocating trade and transportation charges in input-output models. The aggregation problem arises because it is not feasible to divide the economy into homogeneous industries. The number of industries in the model must be kept within manageable bounds by aggregating the industries into groups. Balderston and Whitin discuss the relative merits of some possible aggregation procedures, and also seek to measure the magnitude of the error which can be introduced by the aggregation procedure.

Trade and transportation charges can be considered as inputs either to the buying industry or the selling industry. Modlin and Rosenbluth discuss some of the theoretical problems involved, and the assumptions implicit in each method of allocating these charges. They also demonstrate that the results obtained from the model are quite sensitive to this allocation. In an 18-industry model for 1939, they find that the method of allocation changes their results by more than 10 per cent for over half of the industries.

Unfortunately, this volume has some of the defects so common to collections of this kind. The different parts of this volume are not directed at the same audience, or concerned with the same kinds of problems. Furthermore, there are times when the right hand apparently does not know what the left hand is doing. Thus we find in a discussion of the assumptions of the input-output technique on page 51 the familiar statement that the coefficients of production must be assumed stable, and in another paper on page 166 we are told, in passing, that, "of course," this assumption is not made. The reader would benefit if problems of this kind had been thrashed out before publication.

National Income and Social Accounting

Long-Range Economic Projection. Studies in Income and Wealth, Vol. 16. (Princeton: Princeton University Press, for the National Bureau of Economic Research. 1954. Pp. x, 476. $9.)

To those who judge the worth of economics by its successful predictions, this collection of eleven essays offers evidence that only modest claims are warranted in the present state of knowledge. Although some predictions are attempted, the major emphasis is on techniques of prediction in the funda-

mental areas of productivity and labor force, as well as for fiscal policy, saving and investment, and also for economic sectors ranging from individual industries and agriculture to foreign trade and regions.

According to Simon Kuznets in the introductory essay, the basic premise underlying any forecast is "an identifiable relation between the future and the past, and a minimum of order in the past that can be translated into some specific pattern for the future." In short, a theoretical model consistent with historical regularities is required. In the absence of such a theory, the forecaster is obliged to extrapolate from historically established relationships with a high degree of uncertainty. Goodness of fit, however, is not a sufficient criterion of the usefulness of a function since a variety of functions each fitting the historical data equally well frequently yield widely different forecasts. William Fellner, who explores long-run projection of private investment, suggests that "the predictive usefulness of a theory depends in a large measure on whether it implies a useful separation of 'formal framework' from 'environment.' " This is so because "in economics true projectibility is at present a utopian goal," *i.e.*, no truly comprehensive model exists. To this extent Kuznets and Fellner are in agreement.

The difference between their respective approaches illustrates an important problem in empirical economics and one that is central to prediction problems. In the absence of a generally accepted all-inclusive theory, what weight should be given to the three ingredients inevitably found in any prediction: observed historical regularities, oversimplified theories and "subjective or quasi-intuitive judgment" as Fellner puts it. In the situation envisaged by Kuznets, where numerous hypotheses compatible with observed regularities yield widely different predictions, we select relations on the basis of incompletely tested theories and quasi-intuitive judgment. Fellner, on the other hand, uses an admittedly oversimplified model based on the acceleration principle to predict investment. He therefore puts the greatest emphasis on his interpretation of the *ceteris paribus* conditions since in his view the historically derived parameters are not to be taken too seriously because the parameters themselves are part of the self-adjusting mechanism of the economic system. Hence, the parameters are variables and the forecaster's main task is to judge how they are likely to vary during the forecast period.

The mixture of ingredients used in any projection depends on how much information exists. If the investigator has few observed regularities to work with, oversimplified theories and intuition must play a large, possibly a predominant role. However much reliance must at present be placed on intuitively based forecasts, it seems clear that scientific forecasting is possible only when more mechanical techniques are used because only with such techniques can we begin to track down sources of prediction error. As long as errors are principally ascribable to incorrect intuition, prediction will remain largely an individual matter, a state of affairs that most economists would not relish.

Several of the essays adopt an approach suggested by Kuznets to be an important technique for improving prediction, namely the selection of as many components "as there are sectors in the economy characterized by different

behavior patterns." Harold Wool's treatment of the labor force devotes much attention to the importance of the age and sex distribution for the labor force. For a ten- to fifteen-year period ahead predictions can be reasonably accurate because the youngest members of the labor force as of the prediction date have been born and mortality rates are quite stable. Many unknown sociological considerations become paramount in predicting fertility so that longer-term forecasts are much more uncertain; for example, whether the postwar "baby boom" becomes permanent, which Wool believes is likely.

The analysis of subaggregates also constitutes the focus of Harold J. Barnett's test of the forecasting prowess of input-output. He contrasts the prediction errors of an input-output model with those of a simple regression model (specific industry output as a linear function of gross national product and time) and two naïve models. Barnett finds that the regression predictions are superior to input-output projections while the other methods are somewhat inferior, though the results are not decisive. The only individual industry analysis, that of Paul Boschan, obtains regression estimates for aggregate steel requirements as a function of industrial output and an interestingly derived measure of industrial capacity. A potentially superior alternative to "building in" a measure of cyclical demand variation to account for changes in final output composition would be to attack the matter more directly through input-output. Another study of subaggregates is that of Walter Isard and Guy Freutel. They review some previous theoretical work in the field of regional analysis and present several novel ideas about regional projections and regional interactions. These studies exemplify a general trend toward the use of relatively small units of observation, primarily in recognition of the fact that the behavioral content of the aggregates becomes less and less apparent, the more all-inclusive are the data.

Two studies with empirical content that operate with more aggregative data are those of Fellner on investment and Rex F. Daly on agriculture. Fellner uses decade averages of total investment to derive marginal capital coefficients. These are assumed to be "normal" and are compared to current marginal capital coefficients and the current rate of growth in output in an attempt to determine whether the rate of capital accumulation is consistent with estimated increases in output and saving. Since investment behavior, either in inventories or fixed capital, or in different industrial sectors is likely to be governed by quite different factors, more accurate results might have been obtained had the author used more complete models relevant to the different sectors. Concerning agriculture, James P. Cavin appraises previous forecasts and Rex F. Daly presents a competent although conventional demand study for agricultural output and makes demand projections for 1975.

In addition to a thoughtful discussion of international account concepts, J. J. Polak sets up an equation system in which the long-run demand for imports of other countries is made a function of U. S. imports, each country's capital imports, its exports and its desired reserves. The exclusion of relative prices seems curious in light of widely held beliefs that while the short-run influence of price changes may be small, price effects are much more likely to be potent in the longer run. It might turn out that for prediction purposes

this approach is superior to a price-oriented theory of international trade, although this possibility has not been firmly established.

A succinct and critical appraisal of existing theories of long-run saving by Mary Smelker challenges the notion of a constant secular saving ratio on the grounds that the statistical evidence is inadequate and that the presumed stability of income size distribution does not stand up to close examination. The remainder of her study has been devoted to observations on how income distribution, age distribution, urbanization, the price level, financial assets and consumer durables might affect saving in the future.

Although projections may provide a very rough guide to policy, Arthur Smithies looks upon the possibilities of long-run projections with a sceptical eye, deploring "the amount of time and effort that is now going into the statistical computations of projections which may have little more validity than attempts to guess the height of the emperor of China." Therefore Smithies has concentrated on the impact of fiscal policy, particularly the influence of income redistribution on productivity.

While the volume makes a definite contribution to the topic of long-range forecasting, it is clear that more questions were asked than were answered. This is perhaps as it should be in a field where so little systematic work exists.

EDWIN KUH

The Johns Hopkins University

Individuals' Saving: Volume and Composition. By IRWIN FRIEND with the assistance of VITO NATRELLA. (New York: John Wiley & Sons, 1954. Pp. x, 288. $5.00.)

National income statistics give personal savings as a residual of consumer income and expenditures. The Securities and Exchange Commission gives us the story behind this residual in terms of data on the changes in assets and debts making up savings. The savings concepts used by the two agencies differ in several respects, but this fact is incidental to the important fact that the SEC estimates provide information on the forms assumed by savings. Basic to the SEC series are liquid savings estimates, namely those of cash, savings deposits, insurance and pension reserves, mortgage and consumer debt. Other components of savings, namely home ownership and durable consumer goods, appear in national income statistics.

Estimating processes are described in Part II of the study. It is a story familiar to all economic statisticians, of the adaptation of inadequate source data, collected as by-products of legal and business administration, to a statistical problem of social import. One should not dwell on the inadequacies of the results and the need for better data until he has paid tribute to the ingenuity of the methods. These are imaginative and surprising, as fascinating in their way as studies of marine life in ocean depths, or development of binary-digit calculators.

Consider mortgages, probably the most important category of liquid savings, and one in which the data are better and Friend's methods less subject to criticism than in the others. To estimate this item it has been necessary to assume that: (1) recordings can be estimated correctly from sample volun-

tary reports, (2) repayments can be estimated from data of financial institutions and of government-guaranteed mortgages, (3) individuals and noncorporate business own all mortgages on one- to four-family dwellings other than those held by financial institutions, (4) individuals and noncorporate business own no mortgages on structures other than one- to four-family dwelling units. None of these assumptions is good. In a sense, Friend is challenging economists to do something about such conditions. Fortunately the challenge has not been ignored, since governmental and private economists and Congress itself are giving heed to them.

Although frank discussion of inadequacies of data and comparisons of data bearing on the same categories are better in this volume than in most descriptions of economic statistics, they are not satisfactory. They do not squarely face the problem of setting limits of accuracy. Consider, for example, the comparison of Commerce savings estimates and the SEC estimates. We have an extensive discussion of factors bearing on the comparison but we are not given an appraisal of the accuracy suggested by the results. This reviewer, making his own appraisal, judges that in the postwar period, both the SEC and Commerce estimates are probably correct on an annual basis within about 3 billion dollars on a total that varies between 5 and 25 billion. This is pretty good and argues more favorably for the accuracy of component figures than what we know of the figures themselves. On the other hand, the discrepancies in the two estimates are not serially correlated very closely, so that year-to-year changes may have larger errors than the figures for a year.

A need exists for new language developed out of statistical theory for treating errors in economic statistics. They should be considered as a standard error of an estimating procedure. Suppose category A can be judged to be correct within a certain limit a, with high probability, and likewise B and b. The error of A plus B can be intelligently discussed in terms of a and b and of the correlation of the two errors. Following naturally also is a concept of the errors of changes in time, that is of $A(t) + B(t) - A(t-1) - B(t-1)$. Any other language is awkward and misleading. Without the proper language error discussions must be mealymouthed.

Besides the statistical story, the volume gives us a summary of other findings on savings, and a somewhat cursory economic interpretation of the significance of personal savings. The author believes that investment-savings relationships are important in the explanation of movement in business conditions, stating his views in a Swedish-oriented manner. Had he stuck to this flexible expectational approach, he might have fared better than he did, but he apparently felt obligated to go farther and to embrace the Keynesian postulate of a stable savings function as a justification for his work. We are told: "The reason for focusing attention on the difference between income and consumption is—the belief that if there is a stable relation representing individuals' spending propensities, it is more likely to be between consumption and income than between total expenditures and income" (p. 13). But it turns out that "The precise nature of the saving or consumption function is not known, and there is still some question whether there is in any meaningful sense a stable saving-income relationship either in the short run or long run" (p. 152). Thus,

the findings are negative as regards the existence of a stable aggregative savings function. Moreover doubts are raised as to the usefulness of the savings concept itself. Perhaps, Friend seems to say, the various components of savings should be studied separately and independent of their status in the savings concept.

If we search for findings less fundamental but still of use as tentative hypotheses, we discover a wealth of them. The evidence is strong, for example, that the secular trend in personal savings propensities out of given incomes is either level or downward. Friend also shows that postwar savings can be well explained by regression equations based on savings out of real income in the prewar world. To be sure such equations have not met the acid test of use in forecasting under severe conditions, though they fared pretty well in 1953. Even if proved wrong, such equations have value, since the process of computation and correction of such equations must in itself broaden our knowledge of forces at work in the economy.

From the results of sample surveys of consumer expenditures, the author points out other tentative findings of interest. One which the reviewer found striking is the high importance in savings of entrepreneurial and management groups who seem to account for two-thirds of all personal saving. Friend emphasizes the probable interconnection of savings and investment behavior of such persons. Although expressing fundamental reservations about the results of sample surveys to date, the author considers the potentiality of the survey method as very great.

In Chapters 6-8 the author interprets historical savings data in broader economic terms. This falls short of the theoretical analysis seemingly promised earlier. He is content with a factual summary that hints at important conclusions. From 1929 to 1933, for example, individuals dropped their savings in securities, houses and consumer durable goods tremendously, but liquidated debt and protected their cash and deposit holdings to a surprising extent. This behavior indicated that persons enjoying sustained incomes were retiring debt and accumulating cash, while those with little or no incomes were powerless to lower their cash position or accumulate debt significantly. This suggests in turn that personal savings behavior would not have stabilized the national income at a low level à la Keynes, but in itself would have carried income right down to zero.

In the late 'thirties, high liquidity performance is the striking fact. We learn: "As compared to a negative or small positive figure in the late 1920's individuals' saving in the form of cash and deposits amounted to more than 55 per cent of the adjusted SEC total for the period from 1935 to 1940, and an even higher proportion of the smaller Commerce total" (p. 105).

If the reviewer understands Friend's postwar story of consumer behavior correctly, personal saving was a stabilizing factor in the main. Consumers seem to have contributed a good deal to the inflation of 1947 and 1948, but in the middle of 1948 helped bring it to an end through accumulations of cash and lowered consumer-credit borrowings. In 1949 high consumption and borrowing stabilized the economy by aiding production, and in 1951 their increased saving again acted to prevent inflation.

This book is primarily a source book of fact and summary of findings on savings in relation to income. Economic theory is used mainly to lend perspective and organization. The work should prove useful and stimulating to all empirically minded economists.

PAUL B. SIMPSON

Washington, D.C.

Consumers' Expenditure in the United Kingdom 1900-1919. By A. R. PREST, assisted by A. A. ADAMS. (New York: Cambridge University Press. 1954. Pp. xiii, 196. $7.50.)

This is the third volume in the *Studies in the National Income and Expenditure in the United Kingdom* published under the joint auspices of the National Institute of Economic and Social Research in London and the Department of Applied Economics of the University of Cambridge. It complements Stone's estimates for the period 1920-1938, the first part of which was recently published. The present volume, however, contains only basic data and virtually none of the demand analyses which were a prominent feature of Stone's work.

The items for which series are presented range from demersal fish (whatever that may be) to licenses for armorial bearings. Inevitably many of the estimates are based on very little firm information, although the author has made use of a wide variety of original sources. Perhaps the most interesting result which emerges is that from 1900 to 1913 real consumption per capita rose by only 4 per cent; in real food consumption per capita there was even a slight decline.

In an appendix an attempt is made to assess the reliability of the estimates. Though this assessment is itself dubious enough, the fact that it is there at all deserves praise. Another appendix is devoted to a reconciliation of Prest's figures for 1900-19 with Stone's for 1920-38, the principal difficulty being that Southern Ireland was no longer part of the United Kingdom during the second period.

Dr. Prest's bold and laborious calculations have resulted in a standard work of reference which will be consulted by economic historians and statisticians for many years. It is fitting that it should also be a masterpiece of printing.

Business Fluctuations; Prices

Business Fluctuations and Forecasting. By CARL A. DAUTEN. (Cincinnati: South-Western Publishing Co. 1954. Pp. viii, 518. $5.75.)

This textbook, as its title suggests, undertakes two major objectives, a discussion of the theoretical aspects of business fluctuations and a presentation of various methods of forecasting. The first part of the book is devoted to a study of the nature of business fluctuations. Some attention is given to the trend and seasonal pattern but major attention is focused on the cycle. Regional differences in the trends of various businesses and in their cyclical patterns are also considered.

There is a brief section devoted to the techniques of measuring changes in aggregative economic activity, production and prices. This is followed by a rather lengthy historical description of economic trends and cycles during the period from 1783 to the present.

The theoretical explanation of business fluctuations deals with a limited number of the major types of interpretation with more stress on those elements which are common to various theories than to the differences among them. The purpose of this section is the development of a synthetic approach to be used as the basis for forecasting.

One quarter of the book is devoted to the problems and techniques of forecasting including the projection of trends and various methods of forecasting short-run changes of general business activity. Considerable stress is placed on techniques of forecasting for an industry and for an individual business. The book concludes with a description of the services of various forecasting organizations.

The emphasis of the book is reflected in the fact that the first chapter deals with the role of forecasting in business management and the last chapter describes the services of the more important organizations engaged in publishing forecasts of total economic activity or certain special phases of it. The emphasis is also suggested by the fact that one very brief chapter (20 pages) covers a wide variety of programs for the achievement of economic stability while seven substantial chapters are devoted to forecasting.

The book should find its greatest usefulness in schools of business administration where stress is placed on the significance and the techniques of forecasting or in college courses with this emphasis. It will be of less use as a text in courses where primary stress is placed on theoretical interpretations of economic instability and programs for stability which might follow from such theoretical interpretations.

Each chapter is followed by a thoughtful list of selected readings and a list of questions of both the review and problem type. There is a teachers' manual available to those who use the book as a text.

JAMES F. CUSICK

Dartmouth College

Money and Banking; Short-Term Credit; Consumer Finance

Private Credit and Public Debt. By ANATOL MURAD. (Washington: Public Affairs Press. 1954. Pp. vi, 195. $3.75.)

In this book, Murad develops a theory of credit, weaves it together with a theory of economic stagnation arising from a form of oversaving, and concludes that nothing, not even public debt creation, can save the capitalist system from ultimate collapse and socialism.

Part I of the book is an elaborate attempt to develop a theory of the origin and role of credit which relates credit creation to the fact that exchange is indirect; goods and services produced are not bartered directly for goods and services wanted. Credit arises out of such "uncompleted exchanges." This is followed in Part II by an analysis of the relation of credit creation to eco-

nomic growth. Net capital accumulation calls forth credit which will not be extinguished unless the economy contracts. This credit is represented by income-yielding securities, which provide "income without working" to savers. When savings, aimed primarily at obtaining income without working, outrun the desire of businessmen to invest, depression results. Such depression can be prevented only by the issue of more private credit to finance consumption, or by public credit. This situation, Murad contends, is the fundamental reason for the strong upward trend in the American public debt. War, he says, has not been the basic factor.

Part III argues that net capital accumulation must decline and crises must ensue in a capitalistic economy. In Murad's words: ". . . the portion of output devoted to net capital accumulation may be increasing the beginning of the industrialization process; at some point—the point of diminishing net investment—this proportion must begin to decline because of the ever-increasing demands of the production force on the available labor supply; ultimately these demands must become so great that all the workers are claimed by the production force [output of consumption goods, plus capital replacement], leaving none for the expansion force [capital goods expansion]; at this point, when full industrialization has been reached, net investment must cease entirely" (p. 149). Neither population growth nor technological progress, after an "advanced stage of industrialization" has been reached, provides hope that net investment can draw labor away from utilizing existing productive capacity. Saving continues, however, and only government issue of income-yielding credit can satisfy the demand of savers and postpone the collapse.

But even public spending can only postpone the evil day. Public net investment can no more obtain labor from current production than can private. Murad concludes: "It would seem, therefore, that we are doomed to depression and unemployment—unless we stop saving" (p. 167). The ultimate outcome must be socialism, when saving will cease and public credit can be eliminated.

Murad is to be commended for attempting to merge analysis of the credit system with that of the over-all behavior of the growing economy. But many economists will have grave doubts that he has succeeded.

The basic theory of credit developed in Part I seems to me to add little, if anything, to the more widely accepted understanding of society's credit-debt mechanism (as, for example, summarized in A. G. Hart's *Money, Debt and Economic Activity*), in spite of Murad's diatribe against a somewhat strawman "traditional exposition of money and credit." And serious questions arise in connection with his basic analysis of the process of growth and crisis in a capitalist society. I found several of his central points unconvincing. For example, he argues (without facing up to the statistics) that war has not been the major factor inducing the present large public debt; that saving in a full-employment economy is primarily (exclusively?) induced by the desire of savers for income-producing securities; and that net investment must cease as industrialization proceeds because all labor will be used up by already accumulated productive facilities.

This is a brief book which makes no pretense at presenting elaborate argu-

ment or extensive statistical evidence, but the reader is surely entitled to careful substantiation of such propositions as these. At no point, as far as I can understand the argument, does Murad explain convincingly why his central "principles of diminishing net investment" must even begin to apply, much less why net investment projects could under no circumstances in a "full industrialization" economy bid resources away from consumption goods activities. The supporting argument consists mainly of hypothetical arithmetical examples plus one brief table (p. 140) citing Kuznets' data on net capital formation in relation to national income from 1869 through 1938. The last fifteen years, which show a substantial upturn in the ratio of net capital formation to national income, are, significantly, omitted.

This book is intended as a treatise for economists and serious laymen. I found its basic thesis unconvincing. But the book is lively and stimulating, and Murad warns against the closed minds of present-day monetary economists. Readers especially interested in the fields of money and income-theory thus may wish to investigate Murad's argument for themselves.

G. L. BACH

Carnegie Institute of Technology

Banking Systems. Edited by BENJAMIN H. BECKHART. (New York: Columbia University Press. 1954. Pp. xviii, 934. $13.50.)

This book is a worthy successor to an earlier volume entitled *Foreign Banking Systems,* edited by Professor Beckhart and the late H. Parker Willis.[1] In view of the fact that developments in the area of money and banking have been so extensive since 1929, Beckhart quite properly decided against revising the earlier work and in favor of making a fresh start. As a result, an outstanding book which will be widely used for a number of years to come has been produced.

It will be of interest to those who are familiar with the earlier book to note that there has been some reshuffling of the countries considered. Specifically, Austria, Belgium, Denmark. Norway and South Africa which were included in *Foreign Banking Systems,* are omitted in the new book; and Brazil, Cuba, India, Mexico, and the United States which now receive attention, were formerly excluded. Other countries covered by the new work are Australia, Canada, England, France, Western Germany, Italy, Japan, the Netherlands, Sweden, Switzerland and Russia.

The commercial and central banking systems, savings institutions, urban and rural mortgage credit institutions, cooperative banks, and government credit agencies of each country are treated in detail; and money markets, where they are of significance, are also described. In addition, each section ends with a brief evaluation of the effectiveness with which the existing banking and credit institutions are meeting the needs of the economy of the country concerned.

The contributing authors are unusually well qualified to describe the monetary and banking systems of the respective countries to which they have been assigned. Most of them at one time or another have held private banking con-

[1] New York, 1929.

nections, and many of them have served in government in a financial capacity.

It would be unfair to single out specific sections of the book for attention unless sufficient space were available to permit a review of all of the contributions. The critical comments below, therefore, have purposely been kept rather general.

The discussions of a few countries include an excessive listing of legal references. These are likely to be of interest only to one who is pursuing a research project in the area, and the researcher could easily gather such references from other sources. The average reader is likely to be distracted rather than helped by details of this nature.

An extensive bibliography is listed at the end of the discussion of each country, but in some cases references to pertinent articles in English are not included. This is particularly regrettable in those instances in which there are articles that complement effectively the discussion developed in the book.

As is inevitable in a work of this type, some contributions were obviously completed a year or two earlier than others. Such chronological unevenness as there is would be significant only for the reader who had occasion to compare postwar developments in several different countries.

In a few instances, an unnecessarily detailed listing of the names of individual banks is included. These names will be foreign to and of little importance for most readers.

Finally, and most important of all, it is regrettable that contributors were not encouraged to devote more attention to the question of the relative effectiveness of monetary policies and controls during the period following the second world war. A modest reduction in the amount of descriptive detail and a somewhat greater emphasis upon policy matters would have made the discussion of the various countries more interesting and useful.

The above comments are not intended in any way to detract from the overall excellence of the book. Indeed this is a work which the teacher of money and banking subjects will consider an indispensable part of his professional library. The price makes questionable the feasibility of requiring students to buy the book, but it will undoubtedly be used very extensively for library reference assignments in both undergraduate and graduate money and banking courses.

Coordinating the work of twenty different writers is a formidable editorial undertaking, and Beckhart is to be congratulated upon the skill with which he has guided the work. *Banking Systems* effectively fills a gap which has existed for some time in the money and banking literature.

William P. Snavely

University of Connecticut

Monopoly and Competition in Banking. By David A. Alhadeff. (Berkeley: University of California Press. 1954. Pp. ix, 254. $4.50.)

This scholarly monograph represents a new approach to banking. In this study the techniques of economic analysis developed in the field of industrial organization and control for the main purposes of analyzing manufacturing industries are now applied to the banking industry. The main focus is on con-

centration in branch banking in California, but this case-study approach is set in a framework of banking market analysis not only for California but for the country as a whole.

The point of departure is the conclusive evidence of increasing concentration in California banking due to the favorable branch banking laws there. Whereas the four large California branch banks controlled less than 15 per cent of banking deposits in the state in 1920, by 1950 the ratio was nearly two-thirds. Furthermore, two-thirds of these Big Four deposits were concentrated in the Bank of America with over 500 branches, reputedly now the largest bank in the United States.

What are the effects of this increasing concentration on the various banking markets in California? In seeking to answer this question Alhadeff compares the functioning of the Big Four branch banks not with any theoretically ideal competitive market but with indices of performance of unit banks both in California and in the nation as a whole. The variables compared are output, price, costs of production and profits. The last are measured as: (1) net earnings on loans and investments, (2) net earnings on assets, and (3) net earnings on capital. In addition to comparing directly profits and other performance measures for branch and unit banks of different size, the author analyzes the impact of the large branch banks on three categories of banking markets determined by size of borrower.

Concentration in markets, product or banking, can not be determined simply by reference to the number of firms selling in a given market but only after consideration of the cross-elasticities of demand for all possible substitutes; in short, alternative sources of supply. Alhadeff fits his banking statistics into a threefold breakdown of borrower-loan markets by size of borrower so that his three basic categories for measuring the effects of banking concentration are the markets of large borrowers, intermediate-size borrowers, and small borrowers. The author concludes after examining his statistics that "intermediate-size borrowers in California face far more limited alternative sources of supply than in other parts of the country" (p. 53). Small borrowers face monopolistic or oligopolistic markets whether they deal with unit or branch banks and large borrowers can have recourse to the prime loan market which is, in effect, a national competitive market though subject to the revolving price leadership of a few large New York City banks. (This market is largely competitive because it is interrelated with other submarkets of the money market such as the commercial paper market, bankers' acceptances market, etc.)

The allegedly superior efficiency of branch banks in comparison with unit banks is examined by the author and found wanting. "For various reasons, branch banks do not earn more than unit banks on their loans and investments, and are only of average profitability in terms of their earnings on assets" (p. 192). Although branch banks are more profitable than the largest unit banks on any criterion of profitability, they are in turn surpassed on all three profits criteria by the penultimate size unit bank which is, in fact, the most profitable category of unit bank.

Much of the data in the book is presented in the form of annual averages

for each of the Big Four California branch banks (Bank of America, Security-First National Bank, American Trust and Anglo-California Bank) for the years 1938-1950 inclusive. And although the distinction is made between a legal area, such as a state, and an economic market area, it turns out that for most purposes the legal area of California is also the appropriate banking market area to consider. In general Alhadeff handles his data with theoretical sophistication and carefully compares his empirical conclusions with those which might have been expected from theoretical reasoning based on pure a priori assumptions.

There are times, of course, when Alhadeff seems to stray from the straight and narrow path, as when he asserts: "As a matter of statistical record, therefore, it would seem to follow that the most characteristic product of commercial banks as such is the provision of business loans" (p. 12). Unless for some reason Alhadeff does not regard the purchase and holding of securities as a characteristic product of commercial banks, this interpretation of the statistics is difficult to understand, since his summary Table 1 shows that business loans proper were only 21.4 per cent of the total loans and investments for member banks as of December 31, 1951. (Total loans were 45 per cent of all loans and investments.) Later, he sets the matter straight by referring to banks as multiproduct firms and by stating: "A bank's output can be divided into two main categories: (1) loans and discounts, and (2) investments" (p. 108).

One may also wonder whether or not the analogy of the banking industry with manufacturing industries is not sometimes strained a bit when one reads: "In banking, total assets are a rough gauge of 'capacity' and the ratio of loans and investments to total assets is analogous for banks to the load factor in hydroelectric plants" (p. 57). Why could not the traditional concept of an excess reserve ratio for member banks be used in discussing output performance of banks?

But these are minor imperfections in a work characterized by careful and objective scholarship. This monograph is, in short, an excellent book which can be heartily recommended as desirable reading for all advanced students of money and banking. Aside from the obvious merit of the substance of the book it makes a significant contribution to the application of economic methodology to the field of banking.

John A. Cochran

University of Illinois

Le Banche di Emissione in Italia nel Secolo XIX. By Giuseppe di Nardi. Vol. 8 of a collection of economic history and doctrines directed by Prof. Pasquale Jannacone. (Torino: UTET. 1953. Pp. xii, 436. L. 2700.)

di Nardi's book about the banks of issue in Italy during the 19th century does great credit to the author for the care and craftsmanship with which he has undertaken a difficult and laborious task. He has brought together and sifted a large mass of statistical and other evidence, much of it not readily available, bearing on the development of the Italian banks of issue, and he has told the story in a very stimulating and readable form. Interwoven with the reporting of actual developments is a good deal of discussion of contemporary thinking on banking questions as revealed in the minutes of Board of Directors

meetings and the annual reports of the banks, reports of the Parliamentary commissions of inquiry, in the economic literature and in public debates. For the most part the author lets the evidence speak for itself and refrains from judgments and evaluation; where necessary, however, he does point up flaws in the analysis of contemporaries and their misreading of the evidence.

The story of the period is presented in three main parts, which cover respectively the period before the unification of Italy and the establishment of a national currency, the period from 1866 to 1882 during which Italy had forced paper circulation, and the period from 1883 to 1893, which starts with the resumption of specie payments and ends with the banking crisis of 1893.

The books adds a new chapter to the history of central banking in Europe in the 19th century, and throws interesting light on the process of economic unification of Italy which is usually treated very sketchily in the more general books on the economic history of Europe. It also offers some interesting side glances on the working of the 19th century monetary systems, particularly bimetallism, in a country poor in capital, in a precarious balance-of-payments situation, and engaged in heavy military and economic expenditures to achieve and consolidate national unity. Italy furthermore was greatly affected by the major economic and financial events in the more important European countries, while at the same time it could not significantly influence those developments.

It is not surprising, therefore, that the history of the Italian banks of issue should present peculiar features of its own. These include the fight, throughout the period, of the regional banks of issue of the center and south of Italy against encroachment by the National Bank, which had been the bank of issue of the Piedmont and which, as the process of unification proceeded southward, gradually expanded its scope and influence, in part because of its special relation to the government to which it provided financial assistance; the clearing of bank notes among the banks of issue which, because of their different acceptability by the public, raised particular problems and difficulties for the five smaller banks; the fragmentation of the money market and the coexistence of several discount rates in the same area, the reluctance to use changes in the discount rate as a tool of credit control; the composition of the banks' portfolio and their increasing illiquidity because of heavy long-term investments in agriculture and industry and financing of the construction boom; as well as the almost continuous yielding to pressures for credit expansion and the consequent ignoring of those aspects of the domestic and international picture which at times would have suggested a different policy.

The history of the Italian banks of issue does not contribute much that is new to the understanding of the development and functioning of central banking. The contribution of the book lies rather in the light shed on the role of the banks of issue in the process of political and economic unification and development of Italy. Indeed one wishes that the author had put his account of the policies of the banks of issue even more squarely within the political setting of the period and the financial policies pursued by succeeding governments. This would also have brought out more clearly the extent to which government action or inaction and political forces were responsible for the

actual course of development of the banks of issue. The disregard of government regulations, abusive practices, the ability of the banks to pursue policies which were obviously not in the interest of sound economic development of the country or of effective central bank management and the ignoring of repeated if mild warnings of various commissions of inquiry, leading eventually to the crisis of 1893—all these features can be fully understood only in terms of the political climate, the reluctance and inability of the government to take forceful action and the influence of powerful pressures inside and outside of Parliament. As a result the benefits which political unity had brought about were seriously jeopardized in the economic field.

It is therefore difficult to agree with the author that the main theme during this period was the issue of monopoly vs. competition among the banks of issue. Although this was one aspect of the problem and a convenient slogan for the advocates of competition in which to clothe their more immediate, direct and particularistic interests, the argument that the eventual crisis was caused primarily by the excesses of competition is not convincing. As the author himself points out throughout the book, not only was there surprisingly little competition among the banks of issue in many fields, but the government, yielding partly to political pressures, deflected and blunted the impact of competition, slowing down and hampering the inevitable trend toward a unified and more efficient banking system and greater economic integration.

None of these comments is intended to detract from the significance of the author's contribution. The book not only adds an essential dimension to the economic history of 19th century Italy, but also contributes a novel and very interesting chapter to the economic history of Europe. One looks forward with interest to the second volume, promised by the author, which will bring the history of Italian central banking up to 1943.

WALTER F. STETTNER

U.S. Regional Organisation
Paris, France

Money and Credit. Vol. 1. By MARINOS E. CONSTANTACATOS. (Athens: "Hestia." 1953. Pp. xviii, 145.)

A merchant of Athens has set out, in this small book, to investigate the causes of price fluctuations in this country from 1800 to 1940. The author feels that all of economics must be rewritten—he is especially unhappy with Keynes—and this book serves as the first of a series of volumes toward this end.

He states that price instability is due almost entirely to deviations of the actual growth of the money supply from its "natural" or "divine" or "optimum" growth. The optimum growth is a function of population growth and the "rotation rate of generations," the latter being based on the average length of human life. The optimum growth rate, upon which the entire argument rests, is defined for the first time two-thirds of the way through the book. Even then, the reader will have to refer to a previous work of the

author for a clear statement of the concept. Nowhere does the author attempt to justify the use of the optimum rate, except to state that it flowed from instinct, and to back this up the reader is referred to the writings of Ralph Waldo Emerson.

If the actual rate exceeds the optimum rate of money-supply growth, prices rise; in the opposite case, they fall. The author calls this the Relative Quantity Theory of Money; it is a crude quantity theory in a growth context. The optimum rate is applied not only to the money supply as a whole but to each of its components: currency outside banks and demand deposits. (Actually, without realizing it, the author uses a series for total deposits, including time and savings deposits). The problem is to find which of the two components of the money supply is primarily responsible for price fluctuations. The solution to this problem, according to the author, tells us whether price instability is caused by central bankers (issuers of currency) or by commercial bankers (issuers of deposits). It turns out that deposits and commercial bankers had a stabilizing influence on the price level, and currency and central bankers had a disturbing influence. This result is attributed to "the intrinsic merits of the free market forces, Adam Smith's famous 'invisible hand.'"

However, it is impossible to disregard the influence of the author's hand in this conclusion. Suppose that in some year currency falls and deposits rise (relative to their optimum growth rates), while prices fall. Who is responsible for the price decline? The answer is the central bankers because they permitted the fall in currency, and by so doing denied sufficient reserves to commercial banks. Now, with everything else the same, suppose that prices rise. Whose responsibility is this? There are several answers, most of them commending or apologizing for the actions of commercial bankers. For example, commercial bankers in this case averted "the danger of a further fall in prices." Or, prices rose, not because deposits rose, but as a result of the Balkan Wars. And who can blame commercial bankers for that!

But it is not necessary to pursue this further. The problem itself is a sham. The two components of the money supply, throughout the period under investigation, have not been neatly split up this way between commercial bankers and "central bankers." One has only to recall national bank notes to realize this. Just as important, the implicit assumption that the amount of currency outside banks is solely at the initiative of the issuer is invalid. A "deficient" supply of currency may simply reflect the public's preference between the two components. Furthermore, the author assumes that the significance of currency outside banks is that it acts as the reserves of commercial banks, and this is not true either. It is difficult to think of a more inappropriate banking series with which to measure commercial-bank reserves than that of currency outside banks.

Aside from the component "problem," the analysis as an explanation of past price behavior is clearly deficient. The author's sole reliance on the transactions equation, $MV = PT$, will convince many readers of that. Within this framework, however, the explanation for changes in T in terms of population growth and the rotation rate of generations is woefully inadequate. Moreover,

changes in V are never considered. And when, according to the author's own standards, the wrong series for the money supply is used, the analysis becomes hopeless. All that remains intact is the price series.

We next find that the central bankers are not really to blame for price instability; rather it is the gold standard. The relatively slow growth of our monetary gold stock holds back the growth of central-bank liabilities. The latter in turn holds back the growth of commercial-bank deposits, and this results in a deficient money supply. If the central bank attempts to expand its liabilities unduly, the ratio of gold to these liabilities falls and the bank becomes illiquid. If commercial banks attempt to expand their deposits unduly, the ratio of their reserves to deposits falls and they become illiquid. Either way, the monetary system is doomed. The author illustrates this and allied points over and over again with literally hundreds of equations and numerical examples. The upshot usually is that by the year 2055, if not before, the whole system has blown sky high. "My conclusion is that under the existing credit management the outlook is truly ominous."

It may well be true that fifty or one hundred years hence we shall suffer from too little money if we insist on maintaining the present reserve requirements on both commercial banks and the central bank. Money-supply growth calls for the growth of central-bank liabilities (commercial-bank reserves) and, if reserve requirements on the latter are maintained, the digging implied by this may be more than the gold miners of the world will be up to. However, it is one thing to believe this possible, but quite another to argue that it spells catastrophe. If we cannot dig gold rapidly enough, surely we can create sufficient debt for the monetary system to purchase. Rather than worrying about the liquidity of the system, it would seem more important to concentrate on the alternative means of attaining a proper rate of growth of the money supply. If private debt is forthcoming, due to deficits in the private sector and surpluses in the government sector, commercial banks will probably be the purchasers of some of the debt, and this may necessitate a continual lowering of their reserve requirements. If, on the other hand, public debt is forthcoming, the central bank could be the heavy purchaser and at the same time could even raise reserve requirements on commercial banks. There are many combinations between these extremes. Over the long run, it is important to adopt the optimum combination of open-market purchases, treasury asset acquisitions, and reserve requirement changes that will bring about the proper rate of growth of the money supply. The choice of alternatives implies close cooperation between the fiscal and monetary authorities. It would not seem necessary for them to cooperate closely with the gold miners.

Public Finance

The Theory of Fiscal Economics. By EARL R. ROLPH. (Berkeley and Los Angeles: University of California Press. 1954. Pp. xiv, 310. $4.50.)

As the title indicates, this is a theoretical book containing little institutional

material. It includes chapters on the nature of government economic activities, social costs of government, government and social accounting, the monetary basis of fiscal theory and seven chapters on tax incidence in the broad sense. The analysis is careful, and the writing style is clear and forceful. Rolph had previously presented in journal articles some of the ideas developed more fully in this book and they have already aroused discussion. The book will doubtless receive a great deal of attention from public finance specialists and seems likely to excite some controversy.

The chapter on social accounting sets forth a well-reasoned argument for treating both public and private interest payments and dividends as transfer payments. Rolph rejects the factor-cost method of valuing national product or income on the grounds that it is uncertain that so-called indirect taxes in fact raise prices and that, in any case, price increases should not be concealed, whatever their cause.

In the chapter on monetary theory Rolph contends that private expenditures depend on stocks or assets rather than on income. This conclusion is supported mainly by the argument that income of any period cannot determine consumption (or investment) of that period since two contemporaneous events must be causally independent of each other. Although most economists would probably now concede that wealth or liquid assets as well as income influence consumption, it seems extreme to discard income altogether as an explanatory factor.

As regards incidence, Rolph sets for himself the praiseworthy objective of rescuing the topic from the status of "a series of footnote thoughts on price theory." The great merit of his treatment is his consistent emphasis on general equilibrium or aggregate demand implications. Perhaps his most startling statement is that excise taxes are not shifted to consumers but instead reduce factor returns. He argues that a general excise tax is deflationary and hence will not raise the price level. Furthermore, it will not change relative outputs or prices because there is no untaxed employment to which factors may go when their money returns are reduced. These points had occasionally been recognized, notably by Harry Gunnison Brown, but Rolph deserves credit for developing them more fully. He goes much further, however, and extends the argument to selective excises. A tax on a particular commodity will cause nonspecialized factors to shift from this industry to other employments, and returns in these fields will be forced down. If aggregate money demand and real output remain constant, the tax proceeds will all come out of factor returns and a wide range of industries will be affected. But this reflects only an accounting identity: final expenditures equal factor returns plus excise taxes. It does not necessarily mean that the "burden" or incidence of the excises is on producers. Could we not equally well say that commodity taxes are always paid by buyers since their outlays cover both factor returns and taxes? I am not sure under these circumstances whether it is profitable to discuss whether producers or consumers as a group bear the taxes, but I do feel that Rolph is justified in insisting that the conventional treatment is oversimplified.

The surprising omission is Rolph's failure to consider systematically changes

in relative prices and factor returns. These changes represent tax shifting in the traditional sense and their determination has usually been regarded as the study of incidence. A tax on a particular industry will raise the relative price of its output, unless factors employed by the industry are so highly specialized that they are unable to transfer to other employments; and it will reduce relative factor earnings in the industry, unless the factors are unspecialized and highly mobile. Persons whose tastes run toward consumption of the taxed commodity will be taxed more heavily than other consumers, and owners of specialized factors will be penalized. Surely the beer drinker is right in believing that he is being taxed by the excises on beer and the fur worker in believing that the excise on fur coats depresses his wages. The traditional theory of incidence, which is only an application of price theory, concentrated attention on such changes in relative prices and factor returns. More distant repercussions were neglected, in conformity with the usual partial-equilibrium method. It was not always recognized that this partial-equilibrium theory of incidence, although applicable without serious limitation to small taxes, could not be easily extended to taxes of wide coverage and large yield or to a large group of small taxes considered jointly. Rolph's treatment is a useful corrective for this shortcoming, but in my opinion he goes much too far in discarding traditional incidence theory when he refuses to grant that an increase in relative price of a commodity constitutes "shifting" of a tax to consumers of that commodity.

In discussing import duties, Rolph rejects the proposition laid down by Mill and endorsed to a limited extent by Marshall that these taxes fall partly on foreigners, although he agrees that the duties may turn the terms of trade in favor of the country imposing them. Foreigners do not pay money directly or indirectly into the treasury of the taxing country and hence, according to Rolph, cannot be said to bear the import duties. In the taxing country, Rolph believes that import duties fall on exporters or other producers rather than consumers of imports. Exporters are "taxed" if the duties cause the value of imports (exclusive of tax) to decline, since export receipts cannot in the long run exceed payments for imports. This treatment seems to me to imply too literal an interpretation of the meaning of "taxing the foreigner" and again demonstrates Rolph's refusal to classify a change in relative prices as tax shifting.

Rolph's conclusions regarding the effect of taxes on the incentive to work seem to be close to those that are now rather generally accepted, although the manner of statement may suggest more novelty of substance than I believe actually exists. He accepts the proposition that an income tax lowers the price of leisure and hence, from this point of view, tends to cause people to work less. He also agrees that if a tax reduces the real income of a person it will for this reason give rise to an offsetting tendency to induce more work. He differs from most other writers, however, in stressing the price effect and minimizing the income effect. He argues that for society as a whole taxes serve only to prevent inflation and impose no real burden; the real burden is due to public expenditures. Rolph concedes, however, that taxes may redistribute income and thus have income effects that will partly or wholly offset price effects for certain groups.

In the final chapters, dealing with taxes and investment, Rolph presents a highly sophisticated analysis of tax capitalization. He shows that many discussions are faulty because they are confined to the effect of taxation on expected future yields of assets and take no account of the (usually offsetting) influence on rates of capitalization. I find it quite impossible, however, to accept his conclusion that, under conditions of certainty, taxes will have no effect at all on the rate of investing. This conclusion is based on the flat assertion that people save and invest in order to become wealthy and not to earn a return. Granted that wealth may be desired in itself, surely the possibility of receiving an interest return is an additional motive for saving. Even with the speculative motive for holding cash ruled out, it is hard to see why savers would go to the trouble of investing instead of hoarding if investments offered no return.

International Economics

The Economist in the Twentieth Century: And Other Lectures in Political Economy. By LIONEL ROBBINS. (New York: St. Martin's Press. 1954. Pp. xi, 225. $3.50.)

This collection of lectures, delivered in Rio de Janeiro and elsewhere, deals mainly with problems of international readjustment. Professor Robbins here adds his contribution to the recent array of small but distinguished works—by Robertson, Harrod, Hawtrey and other English economists—on the great postwar disequilibrium.

Inflation in the deficit countries is the villain of the piece. The fiscal methods of inflation control, which Keynes outlined in *How to Pay for the War*, are seen to be subject to serious practical limitations. Failure to use more promptly the tools of monetary policy receives the major blame, but there is hardly any discussion of investment compared with consumption as the proper object of retrenchment. The prescription is: stop inflation, correct the exchange rates. There is full confidence in the efficacy of exchange rate changes; statistical estimates of low elasticities are dismissed as worthless. The author strongly favors, however, the International Monetary Fund's "adjustable peg" procedure, with exchange stability the rule rather than the exception. In his view it is a mistake to rely on continually fluctuating exchange rates as an automatic means of equilibration (pp. 97-101). In the use of import restrictions by deficit countries Robbins admits the case for—at least temporary—discrimination against the surplus country (pp. 57, 144). On the question of sterling convertibility his stand is cautious, because reserves are uncomfortably small. He favors a general increase in the price of gold as a way of restoring international liquidity, but regards it as impracticable at present because of U.S. objections. In place of European union, which he considers too narrow a goal to be attainable, he demands nothing less than integration of the Atlantic Community.

Robbins' views will command wide agreement, though naturally, over so vast a range, there are points to which some will take exception. The author is right when he castigates the habit of keeping domestic and external policy

in closed compartments, but to my mind he goes a little too far in treating a high level of employment and equilibrium in the foreign balance as incompatible. Besides, he devotes a whole chapter to criticizing Beveridge's employment proposals without mentioning the 3 per cent ratio which Beveridge proposed as the normal rate of unemployment, a goal that has turned out to be conservative compared with the actual ratio of 2 per cent or less that has prevailed in England since the war. In the classical theory of commercial policy Robbins perceives a disquieting flaw: the case for unilateral free trade is weakened, in his opinion, by the fact that tariff reductions by one country alone will have deflationary effects on that country's domestic economy, whereas with reciprocal reductions losses are counterbalanced by gains (pp. 135-40). The argument seems incomplete, the concession unfortunate. If employment theory reveals a flaw, that theory can also take care of it, by showing the way to realizing the classical assumption of full employment. Especially for a country with a strong balance of payments there is nothing to prevent the offsetting by means of internal expansion of any deflationary pressures arising from unilateral tariff cuts.

Apart from Beveridge, the only living writer cited more than once is Jacob Viner, "that fine economist and true citizen of the world" (p. 167). Views criticized are generally attributed to "some high authorities" or to other nameless—and consequently somewhat shadowy—characters. The author evidently prefers to stand, urbane and dignified, above the fray of current controversy.

The book begins with some very interesting reflections on the growth in the demand for economists and for the teaching of economics in the last fifty years, and ends with an essay on the British war economy, in which British economists, including Robbins himself, played such an outstanding part.

RAGNAR NURKSE

Columbia University

An International Comparison of National Products and the Purchasing Power of Currencies. By MILTON GILBERT and IRVING KRAVIS (Paris: The Organisation for European Economic Co-operation. 1954. Pp. 203. $3.00.)

This is a prodigious piece of work and an honor to its authors. It is one of the few major pieces of empirical research done in the field since Carrol Wright's work in 1885. Here is a forthright discussion of the methods and problems of comparisons of the gross national products of different countries, plus a detailed showing of the results of one such comparison. The findings will undoubtedly be put to substantial use in international negotiations.

The study is designed to provide "some quantitative measure of the relative economic strength" of member countries of the Organisation for European Economic Co-operation (pp. 13, 64); to "measure the relative economic ability of the five countries to meet the requirements of present-day existence" (p. 18); to assess "the productive ability" of the countries involved (p. 61). Clearly these are all versions of a single purpose. The goal is achieved by binary comparisons of "the flows of final goods and services in the two countries" (p. 63)—namely, the United States and United Kingdom, United States and France, United States and Western Germany, United States and Italy. These

comparisons were made by identifying and pricing "about 250 goods that were comparable in the two countries" (p. 77). The purchasing power equivalents thus computed for a given product—European currency units per U. S. dollar—were weighted together and applied to GNP product class totals—for cereals and cereal products, laundry, dry cleaning, and so on. Data on comparative GNP totals and components, as well as on purchasing power equivalents, are reported for each country both at average European and at United States price weights. The key point of the operation was the direct field collection of prices in the various countries for clothing and shoes, with extensive detailed pricing from unpublished and published official sources for other items. Nearly 80 pages of notes indicate the complexities of the pricing process thus briefly summarized.

Among the major findings of the study are the following:

A. The usual conversion of national product data by exchange rates (as is done, for example, in assessing contributions to the United Nations and other international organizations) has "severe limitations" (p. 16). It tends to understate the internal purchasing power of the national currencies for the items composing their national output. Thus the output of the 4 European countries totals about 50% of the United States total when converted by purchasing power equivalents in this study as compared with only 40% from United Nations conversions.[1]

B. The gross product of the United Kingdom in 1950 (valued at a geometric average of United States and United Kingdom relative prices) amounted to 19.2% of the United States total. For France and Germany the totals ran to about 12%, and for Italy, to 8%.

C. On a per capita basis the United Kingdom's output was 58% as great as the United States'; the French, 48%; the German, 38%; and the Italian, 26%.

D. Data are shown in extensive detail for GNP valued separately by United States and by foreign prices. The "use of United States price weights produces national product figures that are higher by 20 per cent for the United Kingdom, about 25 per cent for France and Germany, and 40 per cent for Italy, than the estimates derived by means of the European price pattern—the base figure in all cases being the actual United States gross national product" (p. 25). A shift in weights from United States to European produced no change in the product totals for some items (domestic service) and a change of more than 100% for others (vegetables and fruits in Italy).

E. An astute discussion of the relationship between quantity and market price ratios indicates the impact of relative prices and output. For autos and other consumer durables European prices are relatively high (high purchasing power equivalents) and consumption relatively low (low quantity ratios). For food, differences between European and

[1] United Nations data from United Nations, *National and Per Capita Incomes of Seventy Countries in 1949*, Statistical Papers, Ser. E, No. 1. Gilbert and Kravis give a figure of 35% rather than 40%—which they derive by using actual exchange rates. In practice the United Nations has used an adjusted exchange rate for the United Kingdom.

United States prices are much less and differences between European and United States consumption levels are much smaller.

Which components primarily account for the per capita gross product in the United States being $674 (or more than 50%) greater than the United Kingdom's and $1,262 (or more than 200%) greater than Italy's? They are actually few in number. In consumption—clothing and household goods, transportation, and miscellaneous. In investment—producers durables. In government—defense. The GNP differences for food, housing, health, education and recreation account for only a small part of the wide gulf between the United States and European GNP. (They are, of course, substantial on an item comparison basis.) The difference in investment expenditures is perhaps the most striking single difference. However, these investment differences are gross, comparable depreciation data being nonexistent. Net investment differences might be less, given the greater body of capital equipment in the United States.

The major contribution of this study is certain to lie in the wealth of detail on GNP components and purchasing power equivalents in the five countries studied. This detail enables the reader to make his own combination of components, and direct his attention to specific items. It is nevertheless worth speculating how well the report answers the questions which it set out to deal with—(1) What is the "relative economic strength" of these four OEEC partners as compared with that of the United States?; (2) What is the relative ability of these countries "to meet the requirements of present-day existence"?

1. References to "relative economic strength" (p. 1) and to efficiency "from an economic standpoint" (p. 25) are made in the context of "real comparisons of national and per capita products." But just what does a comparison of GNP totals tell us about strength, about efficiency? How many officials who compare these GNP totals will understand that one country will have more "economic strength" than another in proportion as it has a more complex financial system (more checks used, more services of financial intermediaries); higher interest rates (more interest paid); more barratry (more legal services); and more residents who take thought of the morrow (more expense of handling life insurance)?[2]

The root of the difficulty lies in the fact that while all legal marketed products enter into the GNP total, the resources used for certain categories of production are committed to that particular use—and are not available for other uses, such as defense output. Comparisons of the economic strength of members of international organizations must reckon with that distinction: resources used in making $100 worth of automobiles may be available for making $100 worth of tanks, but $100 worth of vaudeville services may be quite unusable for any other purpose.

A second difficulty lies in the fact that GNP measures output rather than potential—though the latter is implied in reference to "productive ability"

[2] It is clear that production, of any item, will require the use of real resources and it is for this reason that any legal marketed item is included in the GNP total—whoever the estimator.

(p. 61). Actual output, of course, is a fact, and perhaps the best single measure of capacity. But these are not identical; and this is particularly important where a country may be undergoing substantial economic or administrative change. Thus comparisons of Italian GNP with that of other countries measure productive ability less well than do comparisons for the United Kingdom. Changes in land tenure may bring marked jumps in productivity and hence in output—as the experience in more than one underdeveloped country has indicated.[3] (Even within the confines of this study, of course, one may note the dramatic gain in the German gross product from 1950 to 1952.)

2. A second stated goal of the OEEC report is to "measure the relative economic ability of the five countries to meet the requirements of present-day existence" (p. 18). There is, of course, a broad similarity between the structure and goals of these five economies. But the contribution of this study is beyond the pointing out of broad differences in GNP. It lies, rather, in the measurement of GNP in dollars, and purchasing power equivalents to three significant places. In such a context one may question whether there is a single set of requirements of the kind which would warrant using the GNP totals and purchasing power equivalents for international negotiation.[4]

An extensive argument has taken place about the contribution of distribution per se to economic welfare. The OEEC report takes the only feasible path and includes such costs in GNP. But it is to be hoped that future editions will segregate an estimate of distributive margin so that users can appreciate how this item contributes to GNP differences. Using the ratio of income originating in trade to gross domestic product as a fair approximation of trade margins, one finds that the trade margin differential between the United States and Italy, for example, contributes as much as does the spread in investment to differences between the two countries' "comparative economic ability to meet the requirements of present-day existence."

A further complication is the traditional one that GNP measures only those items which come within reach of the measuring rod of money. Few people would confound the national accounts in a vain attempt at complete inclusion of all nonmonetary items. But equally we must recognize that differences between the United States and these other countries, particularly Italy, are affected by such elements. One of the major differences in consumption, for example, is the "miscellaneous" category, of which a substantial component is interest. Because we "net out" intrasector transactions in computing GNP we recognize a larger share of money lending in the United States (where small-loan companies are incorporated) than we tend to in Italy (where the money lender is more apt to be an individual). Similar considerations apply to consumer expenditures for betting (pari mutuel versus small-scale betting)

[3] *Cf.* Walter Heller in Haskell Wald, ed., *Papers and Proceedings of the Conference on Agricultural Taxation and Economic Development* (Cambridge, Mass., 1954), p. 236. The expansion of the national health program in the United Kingdom led to a 13% rise in medical consultations—a rise which would narrow the United States-United Kingdom GNP differential if medical consultations were priced on an item basis. (Actually the OEEC study simply compared the number of physicians per capita for this component of GNP).

[4] This problem, of course, is equally present when we use exchange rates or international units for deflating national income totals.

for moving (transportation companies versus transactions between individuals) and so on. In sum, we can less accurately speak of these GNP totals measuring "the relative ability of these countries to meet the requirements of present-day existence" than we can say: the United States comes closer to meeting the requirements of present-day existence in the United States through the market mechanism than Italy comes to meeting the requirements of present-day existence in Italy through the market mechanism. The revised statement is somewhat more tautological; it is nevertheless more accurate.

Having considered some of the points which must be borne in mind in using the GNP totals in this report for international comparisons of economic strength and ability to meet present-day needs, we must go somewhat further. For the nature of economic development may well be such that there is a broad correlation between the growth in margins, in services and in the basic investment components which are traditionally the measure of economic power. It may be of interest to those accustomed to use iron and steel output as a simple measure of "economic strength" to compare the results of the OEEC study with the production of crude steel in 1950:

Production of Crude Steel		GNP Valued at Geometric Average of US and European Prices (Gilbert and Kravis)
United States	100	100
United Kingdom	19	19
France	12	13
Germany	14	12
Italy	3	8

The results are strikingly similar except for Italy.

To judge the validity of the Gilbert-Kravis findings one should have spent at least a hundredth as much time in detailed research as have the authors. Certain comments can nevertheless be ventured.

A. The findings of this study are broadly consistent with certain earlier reports. Thus, for example, the Gilbert-Kravis results indicate that United Kingdom consumption in 1950 was roughly 66% of United States. A small-scale study by Adler and Paige for 1948 indicated a ratio of 63%.[5] And the pioneering study in the deflation of GNP, done by Copeland *et al.* for the Combined Production and Resources Board suggested a ratio somewhat above two-thirds for 1943.[6] United Nations comparisons imply a markedly smaller ratio—but conceptual differences could easily account for the difference.[7] The comparisons made by the U. S. State Department in computing foreign

service allowances, the ILO food comparisons, Colin Clark's most recent estimates—these and still other data could usefully be summarized and compared by the authors in a subsequent edition of this study.

B. The basic findings on purchasing power equivalents seem consistent with exchange rates. Thus the United Kingdom exchange rate in 1950 was .357 pounds per dollar—as compared with a purchasing power equivalent for the entire GNP shown here of .288 (U. S. quantities). But the equivalents reported here for clothing and textiles and for producers durables are .316 and .303—or close to the exchange rate, and such items are likely to be representative of major segments of United Kingdom exports. For Germany the exchange rate was 4.20 marks per dollar. The report finds equivalents of 4.26 for coal and 4.42 for producers durables—items which we may take to be reasonably representative of the volume of Germany's coal and metal product exports. One of the major findings of the report is a demonstration that by adding together *all* the items in the national product—food, housing and so on—one arrives at GNP purchasing power equivalents in these four European countries which are markedly better than rates for the particular components which move in foreign trade.

C. The differentials between purchasing power equivalents are sensible for the chief components of the national product. They run in line with the influence which one would expect heavier United States capital investment and greater productivity to exercise. Our relative advantage over other countries is less for those products where labor is the dominant cost, rising steadily as the degree of fabrication increases and greater United States capital investment begins to have its impact.[8]

D. What can we say of the results on their own ground—that of internal consistency? Again, the vast bulk of results are reasonably consistent. A baker's dozen, however, are perplexing. The items designated are those where the relationship of one set of equivalents to the other may be quite reasonable to those acquainted with the country and the data but do raise questions on a priori grounds.

Why, for example, should ratios for entertainment and for "other recreation" be so far apart in Germany and Italy—particularly considering that the entertainment ratios were used in deriving the latter?

Since laundry and barber shop services were directly priced in all countries, and since the overwhelming portion of the price in each instance must be average earnings of proprietors, it is hard to understand why the near identity of ratios in the United Kingdom is so totally absent in Germany and Italy. (Domestic service equivalents—though derived by different means—give ratios very similar to those for barber shops, very different from laundries.)

Why should the housing and residential construction ratios in France and

[8] Particular points, of course, are out of line. It is puzzling why the United Kingdom's purchasing power equivalent for meat and fish should be relatively so advantageous given the heavy volume of meat it must import. It is somewhat more puzzling why the French should apparently be such inefficient producers of shoes. Perhaps the fact that no data were available for this item from official pricing for the French cost of living index, with reports based only on direct pricing (p. 135), may have been responsible.

Italy be so far apart? Does the lower purchasing power equivalent for housing amount to a startling reflection of rent control?[9]

Both nonalcoholic beverages (tea, coffee) and tobacco are imported products in these countries. Yet while both products are above the consumption average in Germany and Italy one falls much lower in the United Kingdom and the other much lower in France.[10]

The ratios for purchased transportation equipment—essentially automobiles—and for producers durables were virtually identical in France and Italy, but diverged widely in the United Kingdom and Germany. Since motor trucks are included in producers durables (presumably with substantial weight) and since automobiles dominate the former group, the reasons for such differences constitute a fascinating question. It is to be hoped that a subsequent edition will give the individual equivalents developed for trucks and other classes of producers durables. We could then determine whether it is weighting that produces this result, difficulties in the procedure of using cost of passenger car per kilogram, or some other circumstance. Since the authors used prices of producers durables in deflating defense goods expenditures, the differences between these two sets of data are also of interest. (Presumably the sharp differences reflect relatively small amounts of equipment being purchased in France and Italy.)

One of the more questionable relationships between purchasing power equivalents is that between total food and the vegetable and fruit group in the United Kingdom and France. That these two countries should appear to be relatively such inefficient producers of fruits and vegetables is a striking presumption worth further study.

E. Almost inevitably the study systematically tends to understate the internal purchasing power of European currencies and the comparative GNP of the four countries. This is so despite the authors' manifest intentions and extreme care. It occurs because of a tendency to write off the greater volume of services and the higher level of quality characteristic of certain European goods.[11]

In summary, this major study should supersede a variety of less careful, less thoughtful, measures. It puts the onus on those who prefer to use exchange rates to deflate national incomes rather than the "equivalents" developed here with such admirable care and effort. And it provides a storehouse of data on differences which prevail between the production patterns and price relationships of these five countries. It is to be hoped that future editions will extend comparisons to still other OEEC members. It is even more to be hoped that, free of the inevitable limitations on an official study, the authors will collabo-

[9] In future editions it would be desirable to measure residential construction cost differentials not merely from the cost of specified brickwork, painting and plastering operations (pp. 194-95) but also to include some allowance for carpentry—the latter accounting for a much larger share of construction costs in most countries.

[10] The ratios shown for tobacco are those at factor cost—hence neither subsidies nor taxes should be a factor here.

[11] *Cf.* p. 88 for a thoughtful discussion of the reasons why some of this is necessary.

rate in a private study of the economic implications and meaning of the materials they have so laboriously and brilliantly put together.

STANLEY LEBERGOTT

Washington, D.C.

American Foreign Assistance. By WILLIAM ADAMS BROWN, JR. and REDVERS OPIE. (Washington: The Brookings Institution. 1953. Pp. xii, 615. $6.00.)

From 1941 through 1952 the United States extended to foreign nations nearly $100 billion in foreign assistance. The funds involved were granted under many labels, for a variety of purposes, and under widely divergent conditions. To recount the history of this unprecedented international flow of funds, and to assess its effectiveness, is the task undertaken by the authors of the volume under review.

Clearly, no study of such scope can satisfy the individual curiosities of all readers, but one can predict without cavil that this will be a standard work on the subject for years to come. It brings together data from a wide range of sources and presents them in intelligible and useful form; it weaves a coherent history of the events and of the motives which prompted such largesse; and it singles out a number of places where American actions may not have been optimally attuned to long-range American interests.

The story, as unfolded here, is one of the reaction, sometimes sluggish and sometimes impetuous, of United States policy to changing conditions in the world of international affairs. Wartime assistance began with a trickle, but became a flood with America's entry into the conflict. Postwar assistance was initially based on the notion that transitional relief was all that was needed, but gradually shifted to the larger-term aims embodied in the European Recovery Program. These aims, themselves conditioned by mutual security motives, were in turn modified after the Korea outbreak, when more strictly military objectives again became dominant.

The appraisal or critique of the programs given by Brown and Opie stays broadly within the framework of the history. The early wartime efforts were too niggardly; recent emphasis on military as opposed to economic assistance may be too short-sighted; during the recovery program period emphasis was placed on prospective dollar deficits rather than the prospective contribution of additional funds to the economic strength of the free world. In addition, the authors take potshots at American attempts to tie strings to grants: for example, the provisions of the Economic Cooperation Administration requiring priorities to be given to the United States as a source of supply for agricultural commodities declared "surplus" here, the provisions regarding shipment of ECA cargoes in American ships, and the arbitary restrictions on East-West trade that have from time to time been built into the assistance machinery.

As may be evident from the above, this volume is essentially a history written by economists with good professional insight and judgment. It is not, and does not pretend to be, an economic analysis of the effects of American assistance on the war effort, the recovery of Europe, or the recent defense mobilization. Accordingly, those who want to know how many of the billions

given in foreign assistance were "wasted," and in what sense, or whether particular branches of our aid program should have been expanded at the expense of others, will have to wait for further studies in this vast and relatively unexplored field.

ARNOLD C. HARBERGER

University of Chicago

Germany's Comeback in the World Market. By LUDWIG ERHARD. (New York: Macmillan. 1954. Pp. 271. $4.50.)

Western Germany is not a free-trade country, inasmuch as its tariff barriers remain relatively high; but it led the European nations in dismantling the prevailing system of import quotas when the European Payments Union offered the opportunity. If the author, Ludwig Erhard, German Minister of Economic Affairs and professor of economics at the University of Bonn, could have his way, currency convertibility, the abolition of import quotas, and the establishment of realistic exchange rates, as well as unconditional most-favored-nation treatment, would be objectives to be achieved by all nations as soon as possible.

Erhard's economic credo pervades the whole book, which was prepared in the foreign trade division of the Federal Ministry of Economics under Herbert Gross as director of research; however, the study is largely a chronological account of German foreign-trade policy, from its postwar beginnings in the three Western zones of occupation, through the summer of 1953, when the book was first published in the German language. Great stress is laid on the importance of trade and clearing agreements in Germany's expanding trade, and considerable space is devoted to the part played by such agreements in helping to solve problems relating to specific countries and currency areas, and in creating new opportunities for German trade. The book should therefore be very useful for anyone dealing with German foreign-trade questions, since the background information and discussion of procedure are extremely comprehensive and are accurately done. However, while focusing on the institutional framework of Germany's trade relations as it evolved after the war, the book only in passing treats certain basic factors such as Germany's monetary reform and its monetary and fiscal policies, which appear to have contributed even more to the country's comeback in the world economy than has the institutional framework.

Interesting from a historical point of view are the sections on foreign trade policy under the Allied Military Government, a period now almost forgotten. The study is quite critical of Allied Military "bureaucracy," holding that it tended to hamper German advances in foreign trade during that period. It acknowledges, however, that prior to the establishing of a sound currency by the currency reform of 1948 (which Erhard helped to prepare), not even "superpatriots" could have achieved a larger volume of trade; it also gives credit to the United States as being the only one of the three Allied powers that urged from the very beginning a return of foreign trade to private hands.

As for the future of German foreign trade, Erhard sees Germany's great opportunity in the expanding markets created by the desire of the less-developed nations for greater industrialization. Germany's technological genius

and its ability to produce the desired equipment should promise a great future for German capital exports to such nations.

Business Administration

L'Organisation rationelle de la distribution (moyen de stabilisation économique). By ERIC BOVET. (Neuchatel, Switzerland: Delachaux & Niestlé. 1954. Pp. 268.)

The author has two purposes: (1) an explanation of the ways in which current methods of distribution in industrialized countries operating under a "free enterprise" system create substantial economic instability and contribute to economic stagnation, and (2) a prescription of policies which will beneficially change methods of distribution.

Major evils of systems of distribution such as exist in the United States and France are, according to Bovet, a failure of changes in demand by ultimate consumers to be communicated promptly and accurately to manufacturers through the channels of distribution. This deficiency in our pricing mechanism creates substantial fluctuations in inventories at all levels in the channels of distribution with cumulative effects that tend to generate self-reinforcing upward or downward movements in the economy. The characteristics of our distributive system which create the malfunctioning of the pricing mechanism are the lack of a pervasive and relatively complete vertical integration and the practice of producing in anticipation of orders rather than to order. These characteristics of our distributive system have become increasingly important and detrimental as the technology and scale of manufacture have changed. In Bovet's view, distribution has not adapted itself to current methods of manufacturing.

There will probably be little disagreement with the view that inventory fluctuations have contributed significantly in recent times to economic instability, or even that instability and the uncertainty which it creates can be deterrents to economic growth. Nor will Bovet fail to find substantial support for his view that legal barriers to vertical integration such as have been created in this country by decisions such as the one handed down in the A & P case are not in the public interest.

It is much more difficult to see merit in the author's diagnosis of the ills of our economic system and especially in his prescriptions for their remedy. Bovet's major themes are that we should integrate vertically and produce to order rather than in anticipation. He admits, however, that vertical integration is often impracticable, as is also production to order. He provides no guides as to how far we should go in these directions, and thus we have no new principles by which entrepreneurs can order their behavior. There has never been much promise in any prescription which seemed to imply that businessmen should seek anything other than what they regard as the well-being of their enterprises.

Bovet does make one specific recommendation of a secondary nature which seems wrong rather than merely not helpful. He recommends that vertically

integrated firms price their products to ultimate consumers on the basis of incremental production costs at the first stage in the process of production rather than on the basis of the cost at the last stage as defined by internal transfer prices. If transfer prices are determined by free negotiation between the integrated units and in the presence of real alternative markets for both buyer and seller, the transfer price thus arrived at is a better (more profitable) guide to managerial pricing than is the current incremental production cost at some earlier stage in production. The use of transfer prices, so determined, seems to be increasing in American business. Even when the conditions just described do not exist, there seems no reason to have regard exclusively for incremental costs at the earliest stage in production as opposed to considering all costs of producing the ultimate market values that are demanded by consumers.

Industrial Organization; Public Regulation of Business

The Attack on Big Business. By J. D. GLOVER (Boston: Division of Research, Graduate School of Business Administration, Harvard University. 1954. Pp. xvi, 375. $4.00.)

Big Enterprise in a Competitive System. By A. D. H. KAPLAN (Washington: The Brookings Institution. 1954. Pp. xii, 269. $4.00.)

A renascent interest in big business has arisen from quarters holding disparate social points of view. Hence, it is not surprising that while Glover was in the process of preparing his thesis that nearly everybody is *against* big business, several books and a spate of articles appeared in its defense.[1] Unfortunately in a way for Professor Glover one such book, Mr. Kaplan's, is reviewed here with his.

Even the most ardent critic of bigness would probably concede during his moments of dispassionate reflection that the composite attack on big business can scarcely claim the support of impeccably coherent logic: big profits suggest monopoly, small profits inefficiency; high prices look like consumer plundering, low prices a tactic for driving out competition; expansion heads off new competition, failure to expand is output restriction. Some scholars attack big business as *monopolistic* but support big labor, big government, and cartelized agriculture; and some condemn big business price rigidities as noncompetitive but champion Fair Trade. Glover's book is essentially a catalog of all these attacks and many others.

But we may concede to Glover that big business has been attacked with irresponsibility and still not erase the problem of bigness. To a society that leaves the determination of the composition and level of a substantial share of its national product to the competitive pricing system, bigness in a market sense *is* a problem, and one that does not diminish—much less disappear—because critics of bigness have sometimes chicaned. Some of the attacks Glover

[1] For example, see D. Lilienthal, *Big Business, a New Era,* and J. K. Galbraith, "The Defense of Business: A Strategic Appraisal," *Harvard Bus. Rev.*, Jan.-Feb., 1954, XXXII, 37-43.

distains are valid, and some others are invalid not because of confusion of the attacker, but because they are not attacks on bigness. Glover fails to distinguish between attacks on bigness and attacks on a host of other things ranging from individualism (p. 232) to industrial society (p. 201) and urban life.

For this reason his final chapter of prescriptions for big business action holds little promise of quieting the criticism. No business action can simultaneously quiet criticisms from such a variety of sources as the Marxists, the apostles of atomization, the critics of business, the critics of individualism, Wayne Morse, T. S. Elliot, John P. Marquand, and George Bernard Shaw.

In contrast to these attackers, Mr. Kaplan has looked upon the structural aspects and performance of big business and found neither a cause for alarm. Big business has, on balance, simply kept pace with the rest of the economy: the largest 5 per cent of the manufacturing establishments hired 55.3 per cent of all manufacturing employees in 1914 and 62.3 per cent in 1947 (the slight increase Kaplan attributes to the second world war); the 100 largest industrial corporations held 24.6 per cent of all industrial assets in 1909 and 26.7 per cent in 1948; they earned 31.1 per cent of all industrial corporate profits before taxes in 1909 and 30.1 per cent in 1948; and between 1929 and 1948 their percentage of all industrial corporate profits after taxes declined from 44.03 per cent to 29.85 per cent. The number of firms is growing more rapidly than total population; noncorporate enterprises still account for almost as large a percentage of the national income as in 1929; and over 70 per cent of the gainfully employed are found in the smaller business units or in the non-business field. In short, the giants have not taken over the country and there is no evidence that they are doing so.

Moreover, big business has performed well and exists in a constant state of competitive turmoil. Kaplan's principal criticism of big business on this score is that it has not matched its brilliance of innovational change with "commensurate ingenuity and boldness in sloughing off parts that no longer gain in efficiency by being integrated with the giant enterprise" (p. 227). But Kaplan concludes: "Big business has not merely been kept effectively subject to a competitive system; on the whole it has also made an essential contribution to its scope, vitality, and effectiveness" (p. 248).

On many of these subjective conclusions Kaplan may be right. However, to this reviewer, his conclusion on the fluidity in the upper echelons of big business rests on unconvincing evidence. Kaplan infers dynamic competition from the high turnover among the largest 100 industrial firms. He divides the 100 largest firms into 21 broad industry classifications, and notes that of the 100 comprising the 1909 list only 36 appear on the 1948 list, and that within each of the 21 industries considerable interchanges and turnovers in positions have occurred. Except by footnote references, he fails to point out that 6 of the original 100 disappeared via the merger route, and that 6 of the largest 100 on the 1948 list resulted from the dissolution of American Tobacco and Standard Oil. However, we may excuse these omissions from his computations on the grounds that the results are neither materially affected nor indicative of competition anyway. It should come as a surprise to no one that between

1909 and 1948 steamship, express, sugar refining, locomotive, and ice companies gave way to producers of automobiles, aircraft, motion pictures, electrical appliances, and rubber tires.

Because Kaplan has used such broad industry classifications we would expect, for the same reason, to find considerable firm turnover and disparate rates of growth during this period within each of the 21 industries. For example, transportation equipment includes producers of farm machinery, pullman cars, locomotives and parts, steamships, automobiles, and aircraft. Within this industry group in the course of 40 years American Locomotive, Baldwin Locomotive, Pressed Steel Car, Railway Steel Spring and American Shipbuilding disappeared from the 100 largest and were replaced by General Motors, Ford, Chrysler, and Curtis-Wright. The fluidity at the top is clearly a result of too broad industry classifications.

The reviewer, with no intention of turning a book review into a major research project, rearranged the firm ranks in accordance with somewhat narrower industry definitions and constructed the following table:

Firm and Industry Classification	*Rank*	
Iron and Steel	*1909*	*1948*
U. S. Steel	1	1
Colorado Fuel and Iron	2	–
Lackawanna Steel	3	–[a]
Republic	4	3
Bethlehem	5	2
Copper		
Amalgamated (Anaconda)	1	1
American Smelting and Refining	2	3
Kennecott	–	2
Nickel		
International	1	1
Meat Packing		
Armour	1	2
Swift	2	1
Cudahy	3	3
Dairy Products		
Borden	1	2
National Dairy	–	1
Transportation Equipment/Excluding Autos and Aircraft		
International Harvester	1	1
Pullman	2	2
American Car and Foundry	3	3
Petroleum		
Standard Oil (Standard of N.J.)	1[b]	1
Standard of Indiana	–[b]	2
Socony-Vacuum	–[b]	3
Standard of California	–[b]	4
Chemicals		
Du Pont	1	1

Firm and Industry Classification	*Rank*	
	1909	*1948*
Coal Mining		
Pittsburgh Coal	1	1
Consolidated Coal	2	–[(c)]
Tobacco		
American Tobacco	1	1
R. J. Reynolds	–[(d)]	2
Liggett & Myers	–[(d)]	3
Electrical Equipment and Machinery		
General Electric	1	1
Westinghouse	2	3
Western Electric	3	2
Rubber		
U. S. Rubber	1	2
Goodyear	–	1
Lumber and Paper		
International Paper	1	1
Containers		
American Can	1	1
Retail Distribution		
Sears-Roebuck	1	1
Glass		
Pittsburgh Plate	1	1
Miscellaneous		
United Fruit	1	1

[(a)] Merged with Bethlehem in 1922
[(b)] Created by dissolution of Standard Oil in 1911
[(c)] Merged with Pittsburgh Coal in 1945
[(d)] Created by dissolution of American Tobacco in 1911.

These rankings scarcely support Kaplan's conclusion that firms are constantly in danger of losing their foothold in their respective industries through the forces of dynamic competition. With but few exceptions the leaders of particular industries in 1909 and 1948 were the same firms. The interchanges in ranks in iron and steel are due almost entirely to merger, and the newcomers in petroleum and tobacco we owe to the Department of Justice. Neither large-scale merger nor dissolution is an integral part of dynamic autonomous change.

In spite of the dubious support his own data give to his principal thesis, however, Kaplan's book contains much useful information and says a great deal that makes sense. And if its readers should conclude that Kaplan has been less critical of big business than he should, they may quickly turn to Glover for a comprehensive footnote on how vigorously and viciously big business can be attacked. The reader's emotions toward big business may possibly undergo violent cyclical swings as he moves between the two books, but they will very probably come to rest in the approximate neighborhood of where they started.

JESSE W. MARKHAM

Princeton University

Fair Competition: The Law and Economics of Antitrust Policy. By JOEL B. DIRLAM and ALFRED E. KAHN. (Ithaca: Cornell University Press. Pp. xi, 307. $4.50.)

In recent years the antitrust laws have come in for increasing criticism. Some critics have charged that the laws now restrict businessmen so much that they discourage the vigorous competition they were designed to protect. Others have asserted that the sort of competition the law attempts to establish is either unobtainable or, in view of the fine performance of an imperfectly competitive American economy, actually undesirable.

In this book Professor Dirlam and Kahn attempt to defend antitrust law against its critics. After summarizing court decisions of the last fifteen years, they conclude that the Sherman and Clayton Acts have not deviated from their historic and proper path. They admit there have been some changes—chiefly with respect to price discrimination—but they are not as great as critics have claimed.

To Dirlam and Kahn the law has not only remained essentially unchanged, but is appropriate and effective as well. Indeed, they say, the law furnishes better standards for judging business forms and practices than does economics. Much of this alleged superiority rests upon the use of "intent" to judge legality. In their judgment, legal criteria are superior both because morality may demand that some actions be proscribed irrespective of their economic effects, and because economists have not supplied useful alternative standards. As is sometimes true of fervent declarations of faith, however, confidence in "intent" is not nearly complete. For, as they put it, intent must be accompanied "by the power (actual or imminent) to restrain or exclude . . ." (p. 54). They classify court decisions according to the types of practices with which they deal: vertical integration, monopolizing, exclusive arrangements, tied-in sales, and price discrimination. I shall confine my comments to the discussions of vertical integration and price discrimination.

With respect to vertical integration, the authors make two key claims, neither of which they systematically prove or explain. First, among other things, vertical integration enables a firm with some monopoly power at one level to *increase* its monopoly power at another. Second, integration forces monopoly misallocations from one level into the others in some way that vertical disintegration would remedy. Both of these assertions are incorrect, as the literature amply demonstrates.[1] In support of the first proposition the authors offer the slender defense that businessmen may not actually try to maximize profits. With an effective economic hypothesis thus abandoned without replacement, it is not surprising that analysis and policy recommendations suffer.

Their economics is unorthodox and mysterious in still other ways. At one point, for example, they are led into what seems to be an attack on the ra-

[1] See, for example, J. J. Spengler, "Vertical Integration and Antitrust Policy," *Jour. Pol. Econ.*, Aug. 1950, LVIII, 347; M. A. Adelman, "Integration and Antitrust Policy," *Harvard Law Rev.*, Nov. 1949, LXIII, 27; R. Bork, "Vertical Integration and the Sherman Act: The Legal History of an Economic Misconception," *Univ. Chicago Law Rev.*, Autumn 1954, XXII, 157; "Comment: Vertical Forestalling under the Antitrust Laws," *Univ. Chicago Law Rev.*, Spring 1952, XIX, 583.

tionale of market pricing. In their words, "Government intervention outside the antitrust laws is probably the only way of assuring fairness in the distribution of scarce materials" (p. 159). If they are correct, it is a discovery worth explaining in detail. Unfortunately, however, they develop neither the details of this deficiency of a pricing system nor the working of their remedy for it.

The discussion of price discrimination suffers in much the same way. In addition to reviewing the standard criticisms of the practice, the authors make the dubious argument that discrimination is bad because it may involve "recoupment." This argument asserts that when a seller discriminates in price, the "lower price to one buyer ordinarily means the price to other buyers will be raised correspondingly" (p. 208). This notion rests upon the explicit assumption that sellers do not seek to maximize profits. Since that hypothesis is consistent with virtually any kind of behavior, it is often unclear why the authors approve or disapprove of a particular court decision or business practice.

After analyzing the cases, Dirlam and Kahn conclude that the antitrust laws have not seriously interfered with efficiency. Not only have the antitrust laws not gone too far; in the case of concentrated industries, "the solution . . . would be to break up excessively concentrated market structures" (p. 281). It is anomalous that the authors find themselves capable of making the same sorts of economic judgments that they find economists generally incompetent to make.

They do find the Robinson-Patman Act to be too confining, and, in a general way, advocate loosening its restrictions somewhat. They apparently advocate this on economic grounds, but at the same time warn that "considerations of equity cannot be abolished in the name of effective competition" (p. 277). Just where this leaves the matter is not absolutely clear.

This book thus has serious defects. Although they profess little confidence in economics, the authors deal with problems that require it, and indeed sometimes advocate its use. Unfortunately the economic analysis they do adopt is weak; there are errors here that betray an inadequate understanding of the economic tools the authors condemn. One example is their contention that the theory of pure competition is inapplicable even when numbers are "infinite" (p. 233).

In addition to technical errors and irrelevancies, there is much here to confound anyone interested in scientific methodology. Terms like "dominance," "strategic superiority," and "leverage," though used often, are not explained. Furthermore, the authors sometimes end up evaluating different variables from those whose analysis they promise.

Although this book recognizes a fascinating and important problem, its approach falls between chairs. It might systematically have defended the law on purely moral, ethical, or other noneconomic grounds. It might, alternatively, have analyzed the law purely in terms of economic principles, or by the systematic use of both economic and noneconomic standards. One major defect of this volume is that it mixes, in unspecified proportions, vague moral values and unsystematic economics.

The book is not without merit. Probably most useful are the summaries

of recent cases and discussions of the ideas of many writers in the field. The substantial bibliography and table of cases are also helpful. More important, we may predict that this volume will add new interest to the stimulating controversy of which it has now become a part.

JOHN S. MCGEE

The University of Chicago

Die Neuordnung der Eisen- u. Stahlindustrie im Gebiet der Bundesrepublik Deutschland ein Bericht der Stahltreuhaendervereinigung. (Münich and Berlin: C. H. Beck. 1954. Pp. xxii, 872. DM. 48.)

This report of the German subgroup operating as the executive arm of the allied control of the German steel industry, between 1949 and 1952, gives an account of its stewardship, which ended with the coming into operation of the Schumann Plan. Together with a description of the (coal and) steel industry, it gives a detailed account of the motives, problems, development, and results of the Allied policy concerning the West German steel industry. Among other things, very interesting insights into a pattern of "workable" imperfect competition emerge. Currently, the technological dynamics in the steel-using industries seem largely to influence the rational pattern for structure and business procedure in the steel-making industry.

The reporting group, with the approval of the allied authorities, did not function merely as a passive subordinate organ of Allied policy but took an active part in the planning and acted as the guardian of justifiable German interest.

The views and actions of the Allied authorities, of the German combines and the trade unions as well as the views of corporation lawyers and experts in international law and of German economic and technical experts are presented if not in the text, then in the annexes which cover about half of the volume. Allied ordinances and decisions concerning the reorganization and the exchanges about this between the industry, the controlling authorities, the German government, the trade unions, etc., are reproduced. A detailed account of the structure of the combines before and after the reorganization is given as well as a description of the pattern of the so-called codetermination between management and labor.

In assessing the merits and demerits of the organization and policy of the industry itself and of the success or otherwise of the Allied reform effort, it must be remembered that the industry had to meet frequent radical changes in environment, and that the goal of Allied policy has shifted from the main emphasis on disarmament and dismantling to one of deconcentration and decartelization and finally to one of reconstruction of an efficient, highly competitive industry and ultimately even to partial restoration of armament production capacities. Finally, the industry, together with the closely united German coal-mining industry, entered into the Western European coal and steel union in the fold of the European Payments Union and the Organization for European Economic Cooperation. This marks the beginning of the end of allied control.

A full appraisal of the industry's performance and of the Allied effort to

improve on it is impossible in the space here available. This reviewer was left with the impression that while the breakup of overly large combines, especially in the case of the German United Steel Works with its 177 subgroups, was called for in the interest of more initiative and flexibility of management, the originally planned horizontal breakup frequently overshot the mark of what was sound in terms of efficient production and marketing. The full separation of the steel works from the vertically integrated coal mines and from the affiliated steel-processing combines (shipyards, construction works, wire and tube industries, etc.) if carried out as planned, would have vastly reduced the competitive capacity of the industry by comparison with its horizontally as well as vertically highly integrated European and American rivals. Also there were inconsistencies in objectives. In view of the rapidly changing general conditions under which the industry operates, the planned schemes for plant structure seem too final and too much oriented to the conditions of a closed German economy, while on the other hand the final financial reorganization is left to the decision of a future independent German government. The only partially accomplished breaking up of vertical and horizontal combines in some instances left truncated bodies which in order to regain efficiency, would have to be reintegrated with others, which is against the purpose of Allied policy, or would have to be supplemented by new installations, which would mean misinvestment of very scarce capital.

In fact, with the end of effective Allied control a movement of reconcentration has already set in. The prewar formal cartels, however, have not made their reappearance.

HERBERT VON BECKERATH

Duke University

Competition and its Regulation. By A. G. PAPANDREOU and J. T. WHEELER. (New York: Prentice-Hall. 1954. Pp. vii, 504. $6.50.)

Professors Papandreou and Wheeler have innovated with considerable success in their new textbook, designed primarily for undergraduate courses in public control of business. Their innovations consist of the presentation of certain conceptual developments of recent years heretofore confined to more advanced and specialized works or to the journals, and a somewhat novel organizational structure in presenting the material. The volume is divided into two parts, the first presenting the analytical tools deemed useful by the authors for understanding the regulation of competition; the second presenting a picture of the development of antitrust policy primarily as evidenced in the important decisions of the courts.

In the theoretical portion of their book Papendreou and Wheeler begin with the concept of the market group, defined in terms of cross-demand and cross-sale schedules. (The cross-sales schedule is that portion of the cross-demand schedule which includes those prices that the rival can make "effective" in the market, *i.e.*, where he has sufficient capacity to make a lower price stick by supplying the increased quantity demanded.) The market group concept and the industry concept (defined on the usual basis of technology and product similarity) are combined to produce the basis for delineating the various

market/industry subgroups which are distinguished in the subsequent analysis. This is followed by an analysis of the crucial decisions of the firm including those as to price, output, product mix, selling effort, investment and price discrimination. The authors rely exclusively on the "break-even chart," and make no use of the traditional marginal analysis.

The innovation which will probably attract most attention for this volume is its presentation of firm behavior in "circular" (oligopolistic) markets in the framework of the theory of games. Lest some potential users of this volume be frightened by this, it should be emphasized that only the simplest and most rudimentary skeleton of game theory appears and no mathematical material is even mentioned. The authors' use of game theory is nothing more than a convenient and helpful way of looking at the various forms of behavior which may appear in oligopolistic markets.

The chapters in the first part, which in addition to the subjects already mentioned discuss buyer-seller relations, entry, and selling outlay and product type in circular subgroups, are designed not only to develop concepts which can be used in analyzing particular cases, but also to serve as the basis for consideration of "Criteria for Public Policy." This serves as the bridge between the two parts of the book and indicates the standards by which antitrust policy is to be evaluated in the second part. The criteria presented are the authors' own variant of "workable competition." With others who identify their views by this term they are unable to come up with a very precise set of rules and they are at pains to confess the unsatisfactory status of their criteria.

Papandreou and Wheeler argue that the public authority should aim at preservation of freedom of competition or "potential competitive pressure" and that to do so the attempt must be made to assure that (1) entrance is free, (2) no firm is coerced to withdraw from the market, and (3) firms do not fix the outcome of the "game" through cooperative action. They then rate the major types and subtypes of market group behavior (independence pattern, cooperative pattern, restrictive pattern, interference pattern) which their analysis has delineated. They recognize the extreme difficulties which such a general prescription faces in applying it to such problems as firm size, vertical integration, dissolution, etc.

The second part of the book is organized along familiar lines under such headings as horizontal coalition, aggressive behavior, firm size, monopoly, fusion (merger), unfair competition, various types of price discrimination, and resale price maintenance. Under each of these headings the historical development of the law is presented with frequent reference to the important cases and extensive quotation from the opinions of the courts. The volume ends with a chapter on enforcement.

It is impossible in the scope of a review to mention all of the points at which the reviewer would like to give a special word of commendation or voice a word of objection or disagreement. In the first category, I would like to compliment the authors' selection of cases and quotations from cases. They have resisted the temptation to reproduce a legal case book and have kept the size of this part of the work surprisingly small, yet they have been able to cover most of the points significant for the economist in evaluating trade regu-

lation. This reviewer has found also that the game concepts are pedagogically useful in helping students understand the nature of what we call "the oligopoly problem." The classification of market and behavior types is also on the whole very satisfactory. Almost everyone teaching in this field has his own particular viewpoint. This book is so organized, and in particular the cases so well selected, that there is ample opportunity for interpretation and evaluation different from the authors'.

On the other side of the ledger, I would question the wisdom of eliminating marginal theory completely, since the break-even analysis proves particularly cumbersome when dealing with some problems such as price discrimination. One's taste here will depend on the training of the students. If most of the students have only a principles course behind them, and particularly where the principles course devotes little time to price theory, then Papandreou and Wheeler's approach may be an asset.

Since the game theory concepts are useful, it seems unfortunate that the authors did not push them just a bit further. One of the most useful parts of game theory for oligopoly analysis appears to be its suggestions as to the rules for coalition formation. While it is probably necessary to introduce the concept of the mixed strategy to deal adequately with this topic, the authors have demonstrated sufficient expositional skill to make one wish they had been more ambitious. Perhaps they will at least include an appendix on this subject in later editions.

A final word regarding the use of this book: it is short enough so that in a semester course other materials can be assigned and discussed. This reviewer has found a desirable complement in one of the industry study books. Papandreou and Wheeler present no empirical material illustrating their analysis except for the snatches of descriptive material included in some of the court opinions quoted. Another possible supplement to this book, and one some teachers will find desirable, is one or more sources which discuss the noncompetitive sectors of the economy where regulatory commissions are relied on instead of the competitive market. The absence of any discussion of other than the competitive sector of our economy will be regarded by some as an unfortunate omission.

In textbooks the proof is in the teaching: I have used Papandreou and Wheeler once and I would use it again. In addition to its usefulness as a textbook it provides a clear and relatively accessible expression of the viewpoint shared by many economists towards the problems discussed and as such may appeal to nonspecialist economists and interested laymen and lawyers.

Land Economics; Agricultural Economics; Economic Geography

Agricultural Policy: Farm Programs and National Welfare. By RAINER SCHICKELE. (New York: McGraw Hill. 1954. Pp. x, 453. $6.50.)

This book is a very comprehensive presentation of the U.S. farm problem. In contrast to other discussions of this topic in which goals of economic policy

are not formulated with full clarity, Schickele offers a thorough discussion of these goals. He postulates "maximum social product" and "optimum income distribution" as basic norms. A number of readers may not object to the norms per se, but to the rather involved way in which they are developed.

Government programs are grouped into, (1) programs for improving resource allocation, (2) farm price policy, and (3) programs for improving income distribution. In the light of the goals of agricultural policy as set up by the author all three groups deserve the painstaking consideration given to their evaluation: the greatest interest, though, centers around the author's analysis of farm price policies.

Among the programs for improving resource allocation the author discusses soil conservation in great detail and shows that a number of conservation measures did not achieve the desired result of improving conservation practices. Conservation payments were frequently made for practices on land which did not require special conservation techniques. The author points out that the public is entitled to clear-cut accounting of costs and accomplishments of various practices; but at the same time he is aware of the administrative difficulties of controls. It would appear that the educational work and the stimulation to individual action are probably the most effective part of the U.S. conservation program.

The author's discussion of farm price policies will arouse objections from all sides. Opponents of support prices for special commodities have shown convincingly that these measures neither promote better income distribution, nor improve resource allocation. Schickele admits that support prices of special commodities have their shortcomings, but he explains their dominant role in all farm programs by their immediate effect on farm incomes: "Farmers look at farm prices much the way industrial workers look at wages." Schickele recommends support prices for wheat, cotton, corn and citrus fruit, pointing out that these commodities are subject to particularly great price fluctuations and play a decisive role in the economic life of wide areas. In addition to price supports for the above mentioned crops, Schickele favors forward prices and production goals for a large number of farm products for which production adjustments can be achieved by shifting variable factors.

The author is well aware of the unsatisfactory effect of the existing support system on income distribution. He therefore suggests a number of measures to alleviate poverty on submarginal farms, and to improve economic prospects of middle-sized farms. He is especially concerned with improving credit facilities, with crop insurance, and with variable debt payment. He analyzes programs to safeguard farmers' ownership of land, and encouragement of farm cooperatives.

While the author's recommendations for raising income standards in general will be accepted by most students of the U.S. farm program, it seems obvious that Schickele is inclined to underrate the effect of the support-price system on the U.S. economy. High support prices are responsible for the accumulation of enormous surpluses in the hands of the government (about $4.2 billion of surplus goods owned by the Commodity Credit Corporation plus $2.9 billion of outstanding loans at the end of 1954). Wheat prices are supported at levels

which cover costs of production on submarginal land and far above costs of low-cost producers in the fertile wheat areas of our country. The high level of these prices has encouraged increased production of wheat all over the world. The disposal of U.S. surpluses on domestic and foreign markets poses one of the most perplexing problems of our economic policy.

Labor

The Theory of Collective Bargaining: A History, Analysis and Criticism of the Principal Theories Which Have Sought to Explain the Effects of Trade Unions and Employers' Associations Upon the Distribution of the Product of Industry. By W. H. HUTT. (Glencoe, Illinois: The Free Press. 1954. Pp. 150. $3.00.)

At a time when the issues of imperfect markets and countervailing power are being widely debated, the reprinting of this book, originally published in 1930, will be of interest to economists. For despite a wealth of recent institutional interpretations of unionism, the *economic* claims of collective bargaining have not received much theoretical attention since the period of active discussion that extends from Thornton in the 'sixties to the Webbs in the late 'nineties of the nineteenth century. So far as the economics of the issues are concerned, we have had a mélange of partial cases and attacks on marginalism, whose collective burden has been to show that unions can raise wages without decreasing employment, but which have not explored the implications for the whole economy. One might even say that of late labor economists have become so preoccupied with the terms of trade under collective bargaining that they have forgotten the whole question of the gains of trade from specialization and division of labor.

Professor Hutt has tried to remedy this situation. He holds that the economic case for collective bargaining reduces to two contentions: (1) if no collective bargaining, the workers' market disadvantage would enable the owners of other productive agencies to appropriate income that would otherwise go to labor; and (2) with collective bargaining workers *in general* can appropriate income from the owners of other agents. Hutt rejects both contentions.

The idea of labor's market disadvantage, he argues, stems from Adam Smith, who tied it to his subsistence theory. First, Smith held that masters combined to force wages down, for which there is little evidence. Second, Smith said that masters also combined to keep wages low, which Hutt says merely means that employers then believed in a "natural rate" and were reluctant to raise wages, though Smith himself made the exception that wages would rise under competitive pressure whenever the rate of saving (reserves) outran the rate of population growth.

Third, Smith claimed that the masters' "necessities" were less pressing than those of the workers. Somewhat contradictorily relative to his exception just noted above, Smith based this notion on the difference in relative reserves.

Thornton and others amplified and further confused this idea, referring vaguely to "inequality of bargaining power," inability to monopolize the sale of labor power, or the perishability of labor services. Yet perishability is equally true of much capital (Nicholson), while storability of labor power might at times actually prove a handicap (N. G. Pierson).

In the 'sixties there also emerged the idea of the indeterminateness of the wage bargain: Thornton and Mill suggested that if two parties bargain in isolation, there may be no unique market-clearing price. Edgeworth developed this idea with his superimposed indifference maps of 1881, but later discounted its practical importance.

Jevons took a somewhat different view of indeterminancy, basing it upon the exchange of a unique and indivisible good sold in perpetuity by a monopolist. Although he did not relate the case to the labor market in his work of 1871, in his *State in Relation to Labour* (1882) he treated combination bargaining as involving a "single object" (indivisable unit), and declared that supply and demand analysis was not applicable. As Hutt says, however, labor quantity would still be a variable, even if the wage were indeterminate. This objection stands unless one presumes Fellner's "all-or-nothing" case, where the wage and quantity of employment are jointly bargained for.

Hutt admits that particular unions can raise wages—for small segments of the wage-earning population but not for *all* labor. One method is to exclude competing units of labor and indirectly some of the cooperants, and if possible to prevent the excluded factors together from re-entering the trade. Another involves the rare case of inelastic labor demand, where consumers and owners of immobile cooperant factors are both exploited. However, the immobility of capital is not permanent: its long-run supply is highly elastic because new capital will avoid a badly squeezed trade and old investments will be liquidated. Further, whatever the method of forcing up wages, the decreased scale of the industry will in time also be accompanied by substitutions of capital for labor.

Hutt also denies that labor in general is immobile and so could be exploited by capital as a whole. Monopsony is at most a specialized and temporary situation and will be overcome by entry of new firms seeking the added profits of temporarily depressed wages.

The argument yields two general conclusions. One is that workers as a whole do not suffer any inherent bargaining disadvantage that, in the absence of collective bargaining, would force wages below competitive levels and presumably towards "subsistence," transferring income to owners of other factors. The other is that collective bargaining cannot extract income from these other factors, converting it to wages for the benefit of labor as a whole. Partial wage gains are not taken ultimately from profits or interest but from consumers, who will pay higher prices for eventually decreased outputs in the affected trades. Since the consumers who lose are mainly wage-earners themselves, what collective bargaining at most can do is to redistribute income within the working class itself. So Hutt concludes that the economic claims of collective bargaining do not stand up. Its justification lies in other directions: regulating hours, conditions, and personnel actions—a domain where the discipline of the market is ineffective.

One possible criticism of the argument is that it probably overrates the mobility of labor. Recent empirical studies would so suggest, though they tend to overstress the range and severity of monopsony.

There is also a question of fact: whether unions in general in this country have had the power and have actually exerted the drastic cost pressure usually attributed to them. This reviewer suspects the over-all answer is negative, that unions pay more attention to demand conditions than is usually credited to them. The whole question has been obscured by too much emphasis upon supposedly inflexible "patterns" generated by and limited to periods of inflation (1941-48, 1950-53) and by the special case of the United Mine Workers.

The author's framework is Marshallian and passes over complex questions of wages and employment during major business fluctuations. The gap is serious, though extenuated because the book was written in 1930. Moreover, while cyclical swings pose new questions outside the neoclassical framework, they do not destroy the useful predictions yielded by the analysis for the important problems with which it is properly concerned. If anything, Hutt might have extended his treatment to consider the connections between capital formation, innovation, population growth, and real wages, matters that tend to be overlooked in our current preoccupation with short-run cases.

While there are many important aspects of unionism that lie outside the domain of economic analysis, this book is a useful and needed reminder that collective bargaining carries economic implications after all. Thus its appearance is most timely.

George H. Hildebrand

University of California, Los Angeles

Labor Mobility and Economic Opportunity. (New York: John Wiley and Sons. 1954. Pp. viii, 118. $3.50.)

There has been some tendency in the past to regard the economics of labor as coincident with the economics of wages. It is gradually becoming clear, however, that the subject includes a second major area—the dynamics of the labor force, the processes of labor mobility, and the structure of labor markets. Pioneer research on these matters was initiated at several American universities during the nineteen thirties. Since 1945, it has flourished on an expanded scale at Pennsylvania, Massachusetts Institute of Technology, Yale, Cornell, Minnesota, California, and a number of other centers. The movement has spread abroad, and one hears of labor mobility studies in London, Stockholm, Rotterdam, Marseilles.

The present volume, sponsored by the Labor Market Research Committee of the Social Science Research Council, marks a stage of consolidation in this general movement. It consists of a series of related essays by E. Wight Bakke, Philip M. Hauser, Clark Kerr, Charles A. Myers, Gladys L. Palmer, and Dale Yoder. Taken together, these essays provide a good review of accomplishments to date and of unresolved issues in the rapidly expanding area of labor market research.

It is not possible in a brief review to give each essay the attention it really deserves. Philip Hauser's chapter on "Mobility in Labor Force Participation"

provides the best summary available anywhere of what we know and do not know about secular, cyclical, and other types of shift in the United States labor force. It includes also a review of wartime changes, and some discussion of labor force projections from the present to 1975. The chapter is rich in statistical information and in footnote references to other sources. The author's appraisal of previous work is penetrating, fair, and candid in pointing out areas of ignorance and unresolved issues.

Clark Kerr, in a brilliantly written essay on "The Balkanization of Labor Markets," indicates some of the ways in which the "natural" or "free" labor market is being altered by the development of institutional rules, particularly rules arising from trade unionism and collective bargaining. He develops the interesting thesis that craft and industrial unionism lead to quite different patterns of labor mobility—in the craft case, horizontal movement at the same occupational level among a variety of employers, and in the industrial case strong attachment to a single employer but with the possibility of vertical movement to better jobs within the firm. These two patterns he terms respectively the "guild" and "manorial" principles of labor market organization. This is only one of several stimulating hypotheses which Kerr propounds as a spur to future research activity.

The core of the book, in a sense, consists of three essays by Charles Myers, Gladys Palmer, and Dale Yoder, which report findings from the authors' studies of mobility within local labor markets. Any student who wishes a bird's-eye view of the present state of knowledge on this subject could not do better than to begin with these chapters. The scholars who have been working on labor mobility in various parts of the country, among whom this reviewer is happy to be included, have made an unusual effort to keep in close touch as their work has proceeded and to achieve some comparability of hypotheses and research techniques. The SSRC Committee, the annual conferences at the University of Minnesota, and a number of other institutional devices have contributed to this end. In consequence, recent research on labor mobility has been "additive" to a degree which is rather unusual in social science. As one examines these three chapters, one finds an encouraging number of conclusions which have been confirmed in several studies carried out at different times and places.

One also finds some interesting conflicts in the evidence, or at any rate in the interpretation of the evidence by different scholars. Thus Myers writes: ". . . both studies point to the fact, also found by Reynolds and Shister, that there is very little systematic search for jobs by workers, or weighing of job alternatives" (p. 76). Miss Palmer, on the other hand, comments: "One gains the impression from a review of the Philadelphia work history records that the workers concerned had a considerable knowledge of labor market conditions and pursued their occupational careers in a purposeful fashion. . . ." (p. 62). This paradox, as both authors realize, may turn out to be more apparent than real. The groups of workers studied were rather different in the various cities, and the Palmer studies emphasized work experience over a decade or more rather than individual job shifts. It may be, as Palmer suggests, ". . . that career framework considerations outweigh accidental circumstances if one looks at the record of jobs *over time*, as distinct from a cross-section view of a number

of single job transactions in a local market at any given time" (p. 66). This is only one of many interesting problems which remain to be cleared up by future work.

An introductory essay by Wight Bakke and a concluding note by Gladys Palmer stress the economic and social implications of labor mobility and pose a series of challenging questions. Thus Bakke inquires ". . . can we undergird the economic and social strength of our nation by adequately and efficiently distributing our labor resources, without destroying, for . . . workers and employers, the free choice and free movement which . . . have encouraged them to loyalty to the American system?" (p. 7). Palmer expresses an opinion that "in a free labor market the costs of 'too much' mobility can be more readily absorbed than the costs of 'too little' mobility" (p. 112), and supports this by some discussion of the limited mobility in European labor markets. There is clearly a range of issues here to which economic theorists have not yet given adequate attention. What precise meaning(s) should be given to the term "mobility" for purposes of general reasoning? How much mobility, and what kind of mobility, is desirable? What does one mean by "too much" or "too little" mobility? What institutional arrangements in the labor market will be conducive to the amount and kind of mobility we want?

A reviewer must stick to his volume. It is pertinent to note, however, that this book appears almost simultaneously with two others: Gladys Palmer, *Labor Mobility in Six Cities*, and Herbert Parnes, *Research on Labor Mobility*. These volumes, both sponsored and published by the Social Science Research Council, should be regarded as companion pieces to the present work. The three together give one a heady feeling that labor economics is coming of age and that it will in time compare favorably, in point of generality and precision, with the more venerable branches of economic science.

LLOYD G. REYNOLDS

Yale University

Labor Mobility in Six Cities. A Report on the Survey of Patterns and Factors in Labor Mobility, 1940-1950. By GLADYS L. PALMER, with the assistance of CAROL P. BRAINERD. (New York: Social Science Research Council. 1954. Pp. xiv, 177. $2.75; paper, $2.25.)

This volume summarizes the findings of the labor mobility project undertaken by the relevant research centers of seven universities[1] in cooperation with the Committee on Labor Market Research of the Social Science Research Council. The raw data analyzed by these centers were composed of ten-year work histories collected in January and February 1951 by the United States Bureau of the Census from workers in sample households in six cities: Chicago, Los Angeles, New Haven, Philadelphia, St. Paul, and San Francisco.

As might be expected, this project has yielded a wealth of statistical information on what are now fairly standard inquiries in labor mobility research—the volume of movement, the contrasts between mobile and immobile workers in

[1] University of California at Berkeley, University of California at Los Angeles, University of Chicago, Massachusetts Institute of Technology, University of Minnesota, University of Pennsylvania, and Yale University.

terms of age, sex, etc., the industrial and occupational direction of the movement, and so on. But for the first time such information is available in a form which lends itself to useful comparative analysis. Hitherto it has been very difficult (if not impossible) to compare the findings of labor mobility studies made by individual scholars either because the studies covered different periods or used different research techniques, or both. But for all practical purposes those obstacles have been removed in this project. It should be noted, however, that the project findings do not lend themselves to any "universal" generalizations because of the limited number of cities involved—not to mention other considerations.

In many respects the patterns of mobility are remarkably similar in the markets studied. Thus, "differences in the incidence of mobility among different groups of workers and the kinds of job shifts made follow a similar pattern in different cities, regardless of whether a city's degree of mobility is relatively high or low. Mobile workers differ from immobile workers in the same ways in Los Angeles and San Francisco, which have the highest job mobility, as in New Haven and Philadelphia, which have the lowest." But, as the preceding quotation indicates, there are differences between the cities in the volume of mobility, which are attributable mainly to "the relative importance of migrants in the city populations." And it is interesting to know that "differences in the industrial structure of the economies of the cities . . . do not account for any appreciable differences in mobility."

To say that the findings of this research project are indispensable for any future labor market study is to spell out the obvious. But indispensable as they are, these findings are only a beginning. For they are essentially aggregative statistical data which merely offer us clues in our search for the more fundamental determinants of labor mobility; clues which are necessary, but hardly sufficient, for an integrated understanding of mobility. This is not to imply that these data cannot be used directly for many a practical policy problem; they clearly can. But the scholar must have more. He cannot be satisfied with merely knowing that younger workers are more mobile than older ones, or that the unskilled move more frequently than the skilled, and so on. He must know *why* that is so—and for reasons far more compelling than the satisfaction of idle intellectual curiosity; there are long-run pragmatic considerations involved. Moreover, important mobility differences between individual workers in the same socio-economic group have to be explained adequately; and here the "group approach," even at the analytic level, is insufficient, for we must perforce dig into personality determinants.[2]

This study has relatively little to say about vertical occupational mobility, since the basic data are far too skimpy in that regard. And yet there is a crying need for a thorough exploration of such mobility, granted that it is the cornerstone of stratification theory which, in turn, is crucial for constructive policy decisions of either the private or public variety.

JOSEPH SHISTER

University of Buffalo

[2] *Cf.* S. M. Small, "Unconscious Determinants of Vocational Choice," *New York State Jour. Medicine*, vol. 53, no. 20.

Research On Labor Mobility: An Appraisal of Research Findings in the United States. By HERBERT S. PARNES. (New York: Social Science Research Council. 1954. Pp. xi, 205. $1.75.)

With this publication the Labor Market Research Committee of the Social Science Research Council brings to a temporary close the program for stimulating research in the area of labor mobility which it started in 1946. During the past year, the Council has published, in addition, the findings of the largest empirical study of labor mobility in the United States to date, *Labor Mobility in Six Cities*, and has sponsored a small volume of interpretive essays, *Labor Mobility and Economic Opportunity* (New York, 1954), written by members of the Labor Market Research Committee and reflecting the mature thoughts of this group on the implications of mobility research for present-day society. The three publications together represent a substantial contribution to students and practitioners in this important field.

Within its limits, and as long as it adheres to its limits, Parnes' volume is a first-rate production. With the general advice of the Labor Market Research Committee, the author analyzed the significant American studies of labor mobility conducted by labor economists since the early 1930's. From these studies Parnes attempted (1) to ascertain the basic concepts, definitions, hypotheses, and methods used and the theoretical and methodological problems encountered, (2) to summarize and appraise the findings of these studies as to the extent, character, and determinants of labor mobility, (3) to relate the empirical results to some of the assumptions and conclusions of economic theory on the process of labor allocation, and (4) to suggest areas for fruitful further research. These four objectives have been accomplished in a thoughtful and skillful fashion. The author has not simply taken the research studies at their face value, but has assessed their weaknesses as well as their contributions with a critical eye.

The major limitations of the volume arise partly from the limits deliberately imposed by the author on the scope of his undertaking and partly from the scarcity of empirical work in important segments of the field. The scope of the volume was limited "to labor mobility only in relation to flexibility of the labor supply," and within this area primarily to short-run economic and demographic factors. The labor-demand side is treated briefly and inadequately as a determinant factor. This delimitation of the scope of the field is serious because it has resulted in the neglect of a number of important studies which focus on sociological, psychological, and political considerations. Indeed, the author violates his own well-expressed and sound judgment:

> Nor does the fact that the study is confined to what might be regarded as the economic, as opposed to the sociological, implications of mobility suggest that each of these is a distinct domain, not to be trespassed upon by specialists in the other. Since the boundaries that divide the social sciences reflect no comparable compartments in real life, research will probably be most fruitful if investigators roam wherever the specific nature of their problems leads them, so long as their competence assures a firm footing. (p. 3)

The emphasis on short-run economic factors is all the more unfortunate in

view of the SSRC's traditional encouragement of cooperation among the several social sciences.

As long as the study concentrates on "the extent and character of labor mobility," the emphasis on short-run economic factors is not too serious—it results in an incomplete but not necessarily distorted picture. However, once attention is turned to the determinants of labor mobility, whether personal or institutional, the inevitable difficulties implied above emerge. The author recognizes the difficulties but the implementation is unsatisfactory.

The chapter dealing with determinants is further handicapped by the scarcity of available data. Whereas the discussion of the extent and character of labor mobility is based almost entirely on empirical studies, the discussion of institutional determinants (to which half of the chapter is devoted) depends heavily on a few theoretical and impressionistic writings by labor economists. The author is so much at a loss for empirical materials in this connection that he feels obliged to refer to two British writings, although he specifically states at the outset of the volume that he is ignoring non-American contributions.

The chapter which may be of greatest interest to general economists is that concerned with the relevancy of labor mobility studies to certain assumptions and conclusions of the neoclassical theories of labor allocation. Specific attention is paid to four questions bearing on three assumptions and one conclusion of these theories: "(1) the extent of workers' knowledge of job opportunities and the ways in which they go about finding and taking jobs; (2) the criteria by which workers make their job decisions; (3) the extent to which the voluntary movement of workers is in the direction of higher paying firms; (4) whether the mobility of workers appears to be effective in reducing differentials in wages and other terms of employment among comparable jobs" (p. 187).

As is well known, empirical studies indicate that the "real" world is much more complex than the models of the neoclassicists. Parnes' analysis reaffirms this view but indicates somewhat more precisely the directions in which neoclassical theory might be modified in order to produce more realistic and useful models.

Although other minor criticisms may be made with respect to this survey (such as the relative neglect of materials on nonmanufacturing workers, the limited reference to mobility in and out of the labor force, and the failure to consider materials bearing on labor mobility in studies not primarily concerned with the subject), Parnes has made a valuable contribution to the field, not only by pointing out significant developments in knowledge in the past two decades but also by indicating the gaps and inadequacies. Indicative of the rapid progress in the field is the fact that since the appearance of the volume, labor mobility studies have been published, for example, by the Universities of Princeton, Illinois, and Columbia, a large-scale project has been launched at the University of Pennsylvania, and studies have been advanced at several universities and by the SSRC itself in the occupational-choice area.

MILTON DERBER

Institute of Labor and Industrial Relations
University of Illinois

Arbitration of Wages. By IRVING BERNSTEIN. (Berkeley and Los Angeles: University of California Press. 1954. Pp. x, 125. $3.50.)

A relatively unknown phase of collective bargaining is the voluntary submission of unresolved wage differences to a neutral third party. Since in peacetime probably less than two per cent of general wage changes are reached in this fashion and since even these are concentrated largely in urban transit or other small firms, this ignorance is no surprise. In the five years here covered in detail, only 209 cases were found.

Nevertheless, as a possible alternative to a strike when negotiations break down over a matter of "a little more or a little less," wage-arbitration is worth this serious study by the former chairman of the Committee on Research of the National Academy of Arbitrators. Not the least useful contribution is the assembling of diverse opinions about the conditions under which such arbitration is likely to succeed.

The main portion of the monograph is devoted to classification and analysis of the cases. Of major interest is the analysis of the grounds stated by the arbitrators as the principal reasons for their decisions: intra-industry and inter-industry comparisons and costs of living, with other arguments usually having little weight. The difficulties in the way of using these criteria (and many others) are fully pointed out. Of course, in some limited classifications the sample is too small to justify generalization.

It is unfortunate that the author did not include an analysis of the arbitrators themselves. In evaluating the principles used it would be helpful to know how frequently certain reasons were advanced by economists or lawyers or others. Many of the quoted decisions were rendered by economists, but one wonders about the many others.

Bernstein has made a twofold contribution: one to general knowledge and the other in providing a ready reference for negotiators considering the possibilities of wage arbitration and unwilling to rely on the limited experience of business or union associates.

H. FABIAN UNDERHILL

Indiana University

Industrial Conflict. Edited by ARTHUR KORNHAUSER, ROBERT DUBIN and ARTHUR M. ROSS. (New York: McGraw-Hill. 1954. Pp. xi, 551. $6.00.)

This work is the result of collaboration in both editing and writing on the part of a psychologist, a sociologist, and an economist. It was prepared for the Society for the Psychological Study of Social Issues; but the three author-editors (each of whom made two separate contributions under his own name, in addition to sharing in two further chapters "by the editors") emphasize the fact that "This volume was conceived as an integrated and genuinely interdisciplinary approach to the issues of industrial conflict in the United States." On the whole, the remaining thirty-odd chapters serve to justify this claim, since they comprise a diversified but clearly classified series of attacks upon the problems of industrial conflict, with the economic aspects by no means underrepresented in relation to the sociological and psychological ones.

Obviously it is impossible, within the confines of a brief review, to analyze

or to mention separately the individual contributions of even a few of the thirty-nine persons who had a hand in this joint effort. Fortunately, however, the material is so well organized and integrated that it lends itself to certain meaningful observations which may serve to indicate what the full text has to offer. This is true partly because the editors have been signally successful in avoiding the poorly coordinated, "jumpy" type of manuscript which so often emerges as the product of group writing and research, and partly because they have provided an enlightening series of interlarding summaries, explanations and interpretations.

The general tone of the work is analytical, probing, skeptical, and sophisticated, rather than doctrinaire, dogmatic or naïve. In countless instances questions are asked rather than answered; and where answers are attempted, they are more likely to be pictured in intermediate greys rather than in absolute blacks or whites, with emphasis upon the qualification that more understanding and insight, as well as more facts, are needed before assured conclusions may be justified.

It is not even assumed that industrial conflict is always and necessarily bad. Whereas economists have been accustomed to thinking of it primarily in terms of overt belligerency, as evidenced particularly in terms of strikes, some sociologists look upon it as a sign of industrial democracy at work, in contrast to others who regard it as evidence of breakdown and disorder; while psychologists may see it as an expression of antagonistic interests and desires, at both the group and individual levels, which may have its therapeutic as well as its dangerous aspects.

But in any case, whether it be a dark cloud with silver linings or without, industrial conflict cannot be allowed to cover the entire horizon. It must be "handled," or curtailed, even though it cannot be (and conceivably should not be) entirely prevented. The major means to this end (coming under the three main categories of procedures for reconciling, compromising or adjudicating controversies, of devices for eliminating the sources of dispute, and of social controls by government) are examined in detail and in a manner which is competent and sometimes challenging but which contains little that is new to knowledgeable students of the field.

It is pointed out, as recent studies have indicated more and more clearly, that the social cost of strikes, taken as a whole, is small enough to be readily tolerable, and thus to justify the continued use of this vital adjunct to collective bargaining. One major exception, the national emergency strike, must necessarily be dealt with by government, but on a basis which allows for a considerable amount of improvisation within a broad framework of indicated expectations. The governmental emergency measures of a democracy in peacetime are inevitably conditioned by public opinion, which seems to be more responsive to direct knowledge and personal identification than to propaganda. By the same token, measures taken by industry to deal with substantive matters such as wages, hours and working conditions are more effective in curtailing conflict than are "communications" measures concerned with changing employee attitudes through morale-building, group-dynamics, or "the human relations approach."

There is repeated emphasis upon the twin facts that trade unionism, in its

pursuit of collective bargaining, has exerted a formalizing and stabilizing effect upon industrial relations, and that its aims and activities have far outrun the relatively narrow objective of merely trying to maximize the earnings of its members.

Although the bulk of the book is concerned with the United States, four brief chapters are devoted to a contrasting examination of the environment of industrial conflict in Sweden, in Soviet Russia, in Nazi Germany, and in the nationalized industries of Great Britain.

ELMO P. HOHMAN

Northwestern University

Industrial Relations and the Government. By WAYNE L. MCNAUGHTON and JOSEPH LAZAR. (New York: McGraw-Hill. 1954. Pp. ix, 531. $6.00.)

The authors of this book, according to the publisher's announcement, recognize that there is more than law to the study of labor and the government. Consequently, while the book is primarily a text in labor law, it includes discussion of the historical, sociological and economic aspects of the problems.

The main structure of the book follows a labor-law format—law applied to the employment relationship, the rights of employers, the rights of employees, and cooperation. Each subject is treated historically, and "other aspects" are fitted in as well as can be expected.

From a layman's standpoint, the law is handled very well; the style is lively and lucid, without sacrificing detail and thoroughness. The strongest feature of the book is the way it shows how the reasoning in court decisions became more and more tortured under old laws, until new laws were obviously required. Any reader should gain valuable insight into the process which changes institutions to fit the times.

The book incorporates new materials, which however are often variations on an old theme. Labor is said to have emerged from the quasiparadise of the guild system, through a Hell of *laissez faire*, toward a Galbraithian paradise of a perfect balance of power, aided by government service functions, rather than regulation. The authors' debt to the Webbs and to the Commons and Perlman works is evident, both in content and in interpretation.

One aspect of this tradition seems to be the belief that the only enemies of employees are crooks or employers and their agents, often including the courts. This belief, in turn, leads to several unsatisfactory generalizations and assumptions. One is that legislation can be interpreted as a pendulum swinging between prolabor and proemployer sentiments (p. 48, p. 160). Another results in a cynical treatment of very real questions involving the freedom of workers to negotiate their own terms of employment (p. 24). A third results in a rather casual treatment of the labor monopoly problem; in this text, this problem is left up in the air (p. 74).

The authors lend recognition but not much understanding to these problems. This is most evident in the discussion of the Taft-Hartley Act (esp. pp. 154-60). With this Act, the pendulum seems at least to have swung into a new dimension, if the analogy has not broken down altogether. We are now concerned with the protection of individuals' rights from attack by labor organizations, as well as with the balancing of bargaining power. But this recent concern for

rights cannot be (and is not) dismissed as pure hypocrisy, as earlier appeals to workers' freedom were.

Since protecting individuals seems to weaken employee organizations, the authors are left with real dilemmas which they cannot resolve. They believe the pendulum has swung too far; but all we can hope for is "maturity, [with which] the importance of regulatory and enforcement functions of the government will diminish, while . . . mediation, conciliation, and arbitration . . . grow" (p. 160).

In sum, this book is a workmanlike job of presenting and implementing a well-worn approach to labor problems. A new approach would be highly desirable, but this book does not supply it.

PAUL W. COOK, JR.

University of Chicago

The System of Industrial Relations in Great Britain. Edited by ALLAN FLANDERS and H. A. CLEGG. (Oxford: Basil Blackwell. 1954. Pp. 380. 30 s.)

In this volume of six essays, a group of British scholars has provided a long-needed and comprehensive view of British industrial relations. The authors, all but one on university staffs, stay within the intent of the subtitle, "Its History, Law and Institutions," and integrate historical development with current practice in concise fashion throughout. The stimulating opening chapter "Social Background" by Asa Briggs, an Oxford historian, ranges from the impact of organization on the factory system to the current status of management and human relations. He bases his interpretation largely on three changes "which have influenced the background of relations between employers and workers—the advance, by no means a continuous advance, of unskilled labour; the rise of socialism; and the growth of the welfare state."

Kahn-Freund, lecturer on labor law at the London School of Economics, gives a meticulous exposition of the "Legal Framework" covering the nature of the work contract and the growth of government participation. He does not overstate the importance of the law:

> There exists something like an inverse correlation between the practical significance of legal sanctions and the degree to which industrial relations have reached a state of maturity. The legal aspect of those obligations on which labour-management relations rest is, from a practical point of view, least important where industrial relations are developed most satisfactorily. There is, perhaps, no major country in the world in which the law has played a less significant role in the shaping of these relations than in Great Britain and in which today the law and the legal profession have less to do with labour relations. In the writer's opinion this is an indication that these relations are fundamentally healthy.

Kahn-Freund continues with a statement of a philosophy which pervades the entire volume. "Reliance on legislation and on legal sanctions for the enforcement of rights and duties between employers and employees may be a symptom of an actual or impending breakdown and, especially on the side of the unions, frequently a sign of weakness, certainly not a sign of strength."

J. D. M. Bell, a Glasgow historian, concisely discusses trade union structure, government, objectives, and methods. His analysis of trade union purposes

moves beyond the traditional improvement of wages, working conditions and the status of workers and includes "extending the area of social control of the nation's economic life, and participating in that control." H. A. Clegg of Oxford provides a much-needed chapter on the extensive organization of both private and public employers for collective bargaining which contrasts strikingly with developments in the United States. The organizational response of employers to union growth presents unique difficulties to the researcher, and the author makes the book's most valuable contribution in an area relatively unexplored to date.

Clegg also collaborates with T. E. Chester, director of The Acton Society Trust, in the chapter on "Joint Consultation" which, like the Whitley system in government service, is of considerable interest but has no substantial parallel in this country. Allan Flanders, senior lecturer in industrial relations at Oxford, provides a chapter on the evolution and process of collective bargaining as both an economic device and a social institution. Flanders emphasizes the difficulties of applying national agreements at the workshop level and raises the basic question of deciding "what is the concern of society as a whole, what should be settled on an industrial scale, and what is the affair of the employees in a single enterprise or a smaller group within it."

The editors make an unnecessary explanation of the "concentration on formal institutions" in view of the recent advance in the "new school of 'human relations in industry.'" Footnote references provide ample compensation for lack of a bibliography. While, with the possible exception of the chapter on employers, little of the book is devoted to new material, the authors have, within the scope of a single volume, produced an extremely well-written and thorough introduction to their subject—probably the best text available in the field.

HARRY STARK

Rutgers University

Industrial Pensions. By CHARLES L. DEARING. (Washington: Brookings Institution. 1954. Pp. x, 310. $3.75.)

Not only in the public thought of the day but also among directly interested groups of employers and organized labor there is much unclear thinking in the matter of industrial pensions. This controversial problem sounds simple when approached in terms of the generalities of labor organizations, and even of governmental agencies. Among the latter are the conclusion that social insurance and pensions should be among the primary charges upon the employer's income, that industrial pension and other welfare schemes are conditions of employment and must be bargained for. Powerful labor groups assert that unilateral employer contributions "belong to the workers," that benefits should be based on need rather than earnings, and that the entire cost burden should be placed upon employers as a means of forcing them to bring about a more adequate federal old age and survivors' insurance program. Dearing has plunged into the heart of this controversial field, and, in a thoroughly scientific fashion has succeeded in clarifying the issues so that they should be understandable to the layman, to employers and to labor leaders alike.

There is presented an historical picture of the pension movement prior to the depression of the 1930's, the effect of the depression in bringing about contributory pension plans with vested rights for employees, and finally the wartime and postwar stimulation of pension plans in the form of employer-financed schemes with little or no vesting of rights for workers short of retirement. The influence of the National Labor Relations Board's interpretation of the law in 1948, and the subsequent Circuit Court of Appeals decision in 1949 setting forth the principle that no employer can initiate, terminate or alter any welfare program, whether contributory or noncontributory, voluntary or compulsory, without collective bargaining are shown to have forced a hasty development of industrial pensions which in many respects are not in the interest of the worker, the employer or the public.

The analysis of the structure and operation of various types of pension plans is invaluable. Dearing, basing his figures on good employment and favorable factors, anticipates by 1960 a participation by about 22 million workers, or approximately two-thirds of the work force which would in any way be eligible for coverage by private pension systems. As to contributions, the author states "In the long run the true economic cost of maintaining a pension system will be determined by the extent to which the claims of future beneficiaries for goods and services can be satisfied out of the enhanced productivity generated by the productive employment of accumulated pension funds." Following an analysis of the amount and nature of industrial pension contributions in the various trade and industry groups, Dearing estimates the annual aggregate contribution needed to support the plans in 1950 at something over $2 billion. Making adjustments for increased coverage, the extension of funding for past services, liberalization of benefits, and a moderate allowance for an increased cost of living, the author reaches a projected payment by companies and employees of about $6.6 billion annually by 1960. He calculates new money savings (including pension contributions) at from $18 to $22 billions annually, and outlets for new capital at $17 to $18 billions, suggesting possible investment problems in the 1960's.

Particularly illuminating for persons directly or indirectly involved with industrial pensions as employers or potential beneficiaries, are the author's appraisal and critique of industrial pension plans, and his discussion of the allocation of responsibility for pension financing. It is pointed out that since not more than 32 per cent of the total labor force can expect coverage, industrial pensions are capable of performing no more than a supplementary role in solving the national problem of old-age security. Most of those covered by existing pension plans must remain with a single employer throughout the major portion of their working life and to normal retirement age in order to realize benefits. The net effect of mandatory collective bargaining, asserts Dearing, has been to freeze inherent defects into the expanding pattern of pension development. Also, the incorporation of need as the basis for pension eligibility by powerful union groups violates the concept of pension contributions as deferred wages, and results in calling upon workers in the higher earning brackets to subsidize the low-wage earners.

The allocation among government, management and individual workers of direct responsibility for provision for old age security should be conditioned by economic standards and social criteria consistent with a free enterprise system.

Sound public policy would seem to place the prime responsibility on the individual, whether operating unilaterally or collectively, for providing the level of retirement income desired beyond that of the federal program. Nevertheless, there is a valid role for industrial management, Dearing states, through pension programs adapted to the operating policies, financial capacity and competitive position of individual corporations.

EARL E. MUNTZ

New York University

Wildcat Strike. By ALVIN W. GOULDNER. (Yellow Springs, Ohio: Antioch Press. 1954. Pp. 179. $3.00.)

The author and his research team had the good luck to be able to study firsthand a wildcat strike from beginning to end in a small (225 employees) gypsum plant. Other research in this plant is reported in the same author's companion volume, *Patterns of Industrial Bureaucracy.*

The author has three objectives: to describe a wildcat strike in detail; to explain why and how it happened; and to develop the "rudiments of a general theory of group tensions." Each objective is accomplished with clarity and perception. Primarily sociological in orientation the study contains material of practical moment for union and management representatives and of factual and academic interest for students of industrial relations and group tensions in several disciplines.

The description and explanation of the strike make up two-thirds of the book. A seemingly stable labor relationship based on close worker-supervisor relations and on fulfillment of worker expectations—an "indulgency pattern"—was disrupted by changes stemming mainly from the economics of postwar competition. Technological innovations, a change of plant managers, and replacements among middle management brought a circular process of tightening supervision, violation of worker indulgency expectations, loss of worker motivation to work and obey, and worker aggressiveness. In the resulting tension an inadequate grievance machinery and a leadership on both sides preoccupied with status and market considerations were incapable of preventing the strike. It was settled by an agreement which safeguarded the status interests of union and company leadership by "bureaucratizing" their relationship without resolving underlying causes of tension. The experienced observer of industrial relations will find little that is analytically new in this part of the study, but the picture of the wildcat strike is unusual for fullness of detail, authenticity, and sureness of understanding.

In the rest of the book the author attempts to generalize the findings of this case study into principles of a general theory of group tensions. He codifies into seventeen general propositions the factors which create tension in social systems; lists seven different "disorganization patterns" into which these tensions arrange themselves; and distinguishes three different patterns of "defenses" or responses to tensions. Some of these principles seem obvious truisms clothed pretentiously, but all ring true, and many provide genuine insight toward the author's goal of erecting a bridge between pure and applied sociology.

VAN D. KENNEDY

University of California, Berkeley

Population; Social Welfare and Living Standards

World Population and Production: Trends and Outlook. By W. S. Woytinsky and E. S. Woytinsky. (New York: Twentieth Century Fund. 1953. Pp. lxii, 1268. $12.00.)

Political arithmetic in the twentieth century is a very different art from that in the seventeenth. The statistical brickmakers, who were formerly hard put to it to find straw, are now embarrassed by an excess of it. Doubtless its quality varies and the problems of selection are more difficult than ever before. Nevertheless the movement from scarcity to abundance is the most outstanding characteristic in this field of human endeavor.

All this is reflected in the 1,268 closely printed pages of this monumental effort of the Woytinskys. It is a work in the tradition, not of mere compilers of statistical tables, but rather of that different species who are inspired by curiosity to probe both quantitatively and qualitatively into the multitudinous activities of man. It is not easy to place it by comparison with other works. It differs from the *Statesman's Year Book* in being organized according to subject-matter and not countries, and in attempting interpretation and tracing antecedents. At some points it may seem to resemble Zimmerman's *World Resources and Industries* but its attempts at interpretation are less ambitious, its range of topics somewhat wider, and its preoccupation with measurement greater. It is rather more quantitative and at some points less detailed in its descriptions than Chisholm's *Handbook of Commercial Geography* (rewritten by Stamp).

It is not surprising that a reference work of this type should have appeared at a time when the volume of statistical material and the extent of specialization are rapidly expanding and only a few professional scholars can hope to follow the numerous and widely scattered publications which reflect this expansion. The present work will undoubtedly be of great value to a wide range of readers, both professional and lay. It is a ready reference, not only to facts but also on some subjects to quantitative methods and even historical origins. The industry that has gone into the work is staggering and if Congressional probers of alleged waste in government belonged to the reading section of the public, they might be expected to point to the fact that two persons have accomplished a task of such magnitude as might have engaged the services of a whole bureau!

It is in no sense a detraction from the Woytinskys' accomplishment to point to a few shortcomings, some of them inevitable in a work of this scope. First, there is the difficulty in keeping such a work up to date. It could presumably be met only by issuing periodic supplements, which, after a time, would grow cumbersome. The size and expense of publication may be a deterrent to new editions: a more modest form of publication, with sparser illustration might possibly have been better adapted to survival.

Next, the range of qualitative material carries with it dangers of lapsing into superficiality at some points. The Woytinskys appear on the whole to have come out well in this respect. No single reviewer can hope to judge the adequacy of all interpretations and selections in so wide-ranging a work. Space

will not permit a detailed examination and two examples only will be discussed here.

First the Huntington theory of the relation of climate to energy is described (p. 29) uncritically without reference to the severe criticisms to which his methods have been subjected and to which he never made an effective reply. Recent studies in the relation of climate to man and animals are not touched on in the text or bibliography.

Second, it is stated (p. 139) that ". . . the net reproduction rate measures the vitality of the population in terms of the *long range* trend, rather than current changes." Also, "A net reproduction rate of 1.0 indicates a state of demographic equilibrium in the long run." These statements may seem plausible, but I do not think I should be alone among population students in regarding them as dangerous and misleading. Not even a trend line calculated empirically to fit a series of annual net reproduction rates, nor even a moving average, let alone the rate for a single year, could claim such properties. No reference is given in the bibliography to the work of Hjanal, Karmel and others in recent years on the net reproduction rate.

In neither of these two examples do I wish to suggest that the authors were obligated to survey the particular points in question in exhaustive detail. But it does seem justifiable to suggest that they would have been better advised to have been more careful in selecting the theories which they described and to have avoided some of the categorical statements which they made. Their discussion on the points in question should have contained either more or less than it did.

These, however, are only points of detail and the feeling with which one closes the work can only be one of admiration for the immense task which the authors have carried to a successful conclusion.

E. F. PENROSE

The Johns Hopkins University

Workmen's Compensation. By HERMAN M. SOMERS and ANNE R. SOMERS. (New York: John Wiley & Sons. 1954. Pp. xv, 341. $6.00.)

Students of social security have long complained that workmen's compensation, the oldest of our social insurance programs, is the one about which least is known. The standard studies of workmen's compensation administration were written between 1924 and 1940: the most recent comprehensive technical book, Larson's *The Law of Workmen's Compensation*, is, as its title suggests, written primarily for lawyers, and the only study which frankly aimed to appraise the achievements of the system by reference to its social objectives, namely Reede's *Adequacy of Workmen's Compensation*, was based on data as of 1940. In contrast to our extensive knowledge of the functioning of other social insurance programs, we have had to be content in the field of workmen's compensation with estimates of total expenditures and until very recently no one had even ventured to estimate the total number of beneficiaries.

It must be admitted that the effort to assess the present system demands great fortitude on the part of the investigator. The many different jurisdictions, the diversity and complexity of the laws, statutory and administrative, the variety

of types and standards of administration, the involvement of private insurance and the shocking paucity of officially released data, coupled with the wide-ranging impact of workmen's compensation legislation which requires the student to delve into the technical literature of law, insurance, medicine and industrial relations probably explain why the field has been so long neglected.

Fortunately Professor and Mrs. Somers have not allowed these obstacles to deter them. They have produced a study which is remarkable not only for the completeness of its coverage and breadth of treatment, but also for the exhaustiveness of the sources and authorities consulted. At long last we are in a position to know what workmen's compensation is like.

The findings reported by the Somers (with a pungency of style that is refreshing in so technical a work) confirm one's worst suspicions. The program has not only failed to keep pace with the changes that have occurred in the economic and social environment since it was inaugurated: it is not even meeting the test of its own original objectives. The annual cost of workmen's compensation is now about $1.3 billions, or about the same as unemployment compensation. Yet neither employers nor workers pay anything like the same attention to its achievements and administration, while the public interest is in effect zero. Of this large sum, only about half goes to workers in the form of benefits: the remainder is consumed by overhead costs, primarily those of insurance but also legal fees and administration. Employers have not reaped the alleged advantages of financing through competitive private insurance carriers because uniform manual rates have been established with expense loadings that reflect the experience of the less efficient carriers (some 200 carriers, many small and inefficient, share in the business) while the more efficient make large profits. Nor do employers enjoy the economies of rates based on national experience. Despite original hopes, the administration is almost incredibly litigious (claimants' legal costs consume between 3.5 and 16.6 per cent of the cash benefits in the different jurisdictions) and the authors maintain that such advances as have been made over the years have come at the expense of ever-increasing complexity, ambiguity, litigiousness and costliness.

In fact, apart from some growth in medical benefits, the advances are difficult to discern. The fixed dollar maximums and the limits to duration have resulted in payments that today cover little more than one-third of wage loss, while for the permanently injured and survivors of deceased workers the percentage is around 20. Although expenditures on medical care have increased, the medical program has grave deficiencies and is subject to little supervision or qualitative control. Rehabilitation, which might have been expected to be an area in which workmen's compensation would excel, has been disappointing, with the notable exception of the programs of one or two insurance companies. Indeed, the chapter on rehabilitation is perhaps the most dismal of all for it is a record of missed opportunity. The state administrations have in general been starved of appropriations, and salaries are disgracefully low in view of the highly technical nature of the work. Officials have been relatively helpless in the face of the powerful insurance and medical groups whom in theory they should supervise and control. Even in regard to prevention, the much-advertized achievements of workmen's compensation are, the Somers suggest, largely

in the past: other influences today far surpass those exerted by the workmen's compensation system.

What then is the future of this once important social security program? It is here, perhaps, that the authors are least satisfactory. They appear to place their faith in the further development of the already substantial number of supplementary security systems, some public, some private, which in total somewhat mitigate the deficiencies of workmen's compensation. But as they admit, this complex series of measures involves much overlapping and considerable duplication of payments while offering no assurance that all cases of need for income or medical care will be provided for. Moreover, this duplicating series of programs is costly, and while it may be true, as some European observers hold, that America is rich enough to afford a wasteful social security system, it is difficult not to think that sooner or later both employers and workers will begin to ask whether they could not get better value for the many premiums and social security taxes they pay. The Somers recognize that the future of workmen's compensation will be greatly affected by what action the nation takes in regard to temporary and permanent disability insurance and the socialization of the costs of medical care through social insurance or otherwise. But one would have welcomed a more specific indication of the precise role of workmen's compensation on the basis of alternative hypotheses as to the trend of social security legislation in general. For the question that is left in the reader's mind is whether workmen's compensation is worth salvaging.

But although the authors refrain from indicating the long-run solutions they would prefer, their study will rank as one of the most important books that has appeared in the field of social security for many years. It fills in an admirable way a major gap in our knowledge of social security institutions that had too long existed. And now that the inadequacies and inefficiencies of workmen's compensation have been so fully documented, the book will surely act as a powerful stimulus to a reconsideration of the role of this program, and, so long as it continues in existence, to legislative and administrative reforms.

EVELINE M. BURNS

New York School of Social Work, Columbia University

Our Needy Aged: A California Study of a National Problem. By FLOYD A. BOND, RAY E. BABER, JOHN H. VIEG, LOUIS B. PERRY, ALVIN H. SCAFF, and LUTHER J. LEE, JR. (New York: Henry Holt. 1954. Pp. xxx, 401. $4.50.)

Old Age Assistance (OAA) receives heavy financial support from the federal government. It is administered by state and local governments and consequently the magnitude, benefits and eligibility requirements vary widely among the states. California's program is in many ways distinctive: it is the most ambitious, the most publicized, and the most controversial.

This first full-scale study of the California program by a team of Pomona College social scientists will command wide attention because of its unhesitating recommendations with respect to all of the controversial features of the program.

The study is comprehensive. Its ten chapters concern: the socio-economic

characteristics of California's aged; the historical and political background of the present OAA program; the substantive provisions of the California law, its differences from that of other states, and the administrative experience under it; the costs of OAA in California and nationally; attitudes and opinions of the aged and of the county administrators toward the program; and, finally, a set of recommendations.

The major contribution of the study is the wealth of material newly developed by a special 1952 survey of 890 of California's noninstitutional aged, of which roughly one-third received assistance. Based upon this survey (and other sources) a number of findings emerge, among them: (1) California has more people on OAA and more aggregate expense than any other state. (2) California's aged are typically much better off than those in other states, and OAA is largely responsible. (Whether this indicates merely that the program is more nearly adequate, or whether it indicates extravagance is an important question that is not analyzed.) (3) Despite its relative attractiveness, OAA has not drawn a disproportionately large group of indigent aged into the state. (4) Large increases in the size of maximum grants (from $35 to $80 since 1935) have been partially reflected in real terms (from $35 to $41) over the same period.

Usefulness of some of the data presented is impaired by insufficient attention to questions of statistical significance (the methodological appendix is not adequate in this respect), and by the unfortunately limited amount of cross-classification of the data that is, I imagine, a consequence of the smallness of the sample. Notwithstanding, the data are useful, and it is regrettable that the basic data are not fully presented in an appendix.

The attitudinal data are interesting, but the biases of the respondents are insufficiently considered for the attitudes to have the evidential value that they are later given. Majority opinions of the present group of age toward eligibility requirements quite naturally reflect the majority characteristics of the group with respect to age, citizenship, length of residence, and so on. The bias of county administrators is to keep their administrative burden in hand (" 'We would be swamped' if the requirement [of citizenship] were removed. . . ." [p. 308]). A further difficulty is the failure to analyze opinions in terms of key variables: "The reported ability of children to help support their parents varies with the parents' educational level" (p. 298)—and, I suspect, with children's income.

Among the controversial recommendations concerning eligibility for OAA are retention of the citizenship requirement, more stringent property limitations, and retention and strengthening of relatives' responsibility. Also recommended are provisions for reimbursement to the state from the estates of recipients, and for a continuation of county (rather than state) administration.

To understand the recommendations it is necessary to recognize an implicit and unestablished premise that virtually preoccupies the authors: the cost of the program is in imminent danger of becoming *too high*. This premise might be justified if either the burden of the program is (or promises to become) oppressive, or if the level of payments to individuals is extravagant. Despite an occasional disclaimer the former is the apparent fear of the authors. The cost in 1953 of the program was $226 million, of which about half was paid by the

federal government. The reasons given for thinking this is excessive are: (1) this amount is about 9 per cent of the total expenditures of the State and local governments (almost as much as is spent for highways and bridges), (2) it amounts to about $20 per capita, (3) it is high relative to expenditures in any other state. This evidence is not sufficient, and the issue is too central to be resolved by assumption.

Disagreement with some of the recommendations is beside the point. The point is that most of the recommendations do not emerge from the evidence of the study. Consider the citizenship requirements, which are recommended for the following six reasons (pp. 347-49): (1) three-fifths of the county directors and four-fifths of all the aged in the survey favored it, (2) the proximity of California to the Mexican border, (3) the availability of general relief to those not on OAA, (4) the process of becoming a citizen is not a very difficult one, (5) dropping the requirement would make enforcement of the immigration laws more difficult, and (6) the alternative would cost an additional $35 million to a state which is already spending more than twice the amount of any other state. Of these points only the first, which is irrelevant, and the last, the significance of which is unestablished, emerge from the study.

Relatives' responsibility is endorsed "because it is sound in principle, both morally and economically" (p. 352). Most surprising is the recommendation concerning county administration. The showing in previous chapters of unequal burdens on the counties, of uneven administration among counties, and related findings led, I thought, to the opposite conclusion. The chief explanation is the authors' belief that "local and State governments have both suffered in recent decades from the transfer of some of their functions to higher levels" (p. 367).

The authors are entitled to their judgments, which neither enhance nor detract from their substantial substantive findings. My chief concern is that these opinions will be given undue credence because they are found at the end of a long book.

PETER O. STEINER

University of California, Berkeley

Contributions of Survey Methods to Economics. Edited by LAWRENCE R. KLEIN. With papers by GEORGE KATONA, LAWRENCE R. KLEIN, JOHN B. LANSING, JAMES N. MORGAN, Survey Research Center, University of Michigan. (New York: Columbia University Press. 1954. Pp. ix, 269. $5.00.)

This is not a book for purists. It is the record of a program of research in process of development, and a composite portrait of a new school of believers in an interdisciplinary approach to economics. The aim of this school is to wed economics and psychology through the method of direct surveys. If the concepts employed seem at times somewhat forced or fuzzy, we must remember that the first steps in a new field are necessarily halting and sometimes misguided. If technical machinery is wrenched into services it was never designed to perform, we must respect the will to get on with the work at hand rather than be content with blueprints for perfection. If emphasis on the scientific character of the enterprise seems rather too insistent and at times pedantic, we must recognize the soundness of the inspiration and respect the ideal aimed

at. And, finally, if the book shows flashes of real genius and contains analysis of the first rank, we must credit these to the vitality of a sound idea in attracting exceptional talent.

The book opens with a long and informative chapter by J. B. Lansing on the concept of consuming unit and the accounting framework used to record consumers' economic behavior. Next is a chapter by George Katona outlining a theory of consumer behavior in which psychological and institutional elements are prominent, and to which the results of re-interview surveys are shown to lend support. There follow two chapters by J. N. Morgan on the determinants of consumer saving; these are similar in theoretical inspiration to Katona's chapter, but they are distinguished by the use of a "net worth" concept of saving (which includes spending on durable consumer goods) and by truly heroic efforts to employ the tools of "analysis of variance." Nearly all practicing statisticians do this sort of thing, and hardly anyone likes the other fellow's compromises; but, on balance, Morgan seems not to claim to have proved too much. The final substantive chapter, by L. R. Klein, adduces an econometric model of consumers' saving behavior which incorporates most of the variables—economic, demographic, and attitudinal—that Katona and Morgan find to be influential. The model provides an interesting case of nonlinear relationships among economics variables, and leads to an important qualification of the relationship between real wealth and spending that has figured so prominently in monetary and fiscal theory. The book is introduced by an apt summary of contents and closes with some thoughtful comments on the role of survey methods in business cycle research—both by the editor.

The book is a contribution on several levels. It adds to our knowledge of consumer behavior. Its structure recapitulates the stages—sometimes groping, sometimes inspired, but generally gaining in authority—through which a program of empirical research usually passes; and it will therefore give depth and realism to discussions of research methodology. But best of all, it teaches us something about the Survey Research Center. Here is an organization with an unrivaled body of data on consumer behavior that has not been made generally available to scholars. Like high explosive, it is to be handled only by experts, which usually means that mixed breed psycho-socio-economist. Now we are given an account of the tricky stuff, are told some of the reasons it is difficult to handle, and are shown some of the expedients by which it can be made to yield up its lessons. One gains the impression that the stuff is in competent hands, but neither the difficulties nor the expedients seem half so esoteric as we were led to expect. There may even be simple economists among us who feel that the stuff should be declassified.

MILLARD HASTAY

National Bureau of Economic Research

Consumer Behavior: The Dynamics of Consumer Reaction. Edited by LINCOLN H. CLARK. (New York: New York University Press. 1954. Pp. viii, 128. $4.00.)

This handsomely printed volume is the first issue of a proposed annual pub-

lication, the product of a new Committee for Research on Consumer Attitudes and Behavior, based at Ann Arbor, Michigan. Active leaders include members of the Survey Research Center, University of Michigan, but the participants have included representatives from several universities and several disciplines, a number of market-research agencies, and others from the nonacademic world. Consumers Union has contributed financial support.

The exploratory studies here presented range "over a variety of problems connected with consumer decision and choice." George Katona and Eva Mueller, joint authors of *Consumer Attitudes and Demand, 1950-1952* (1953), present two thoughtful papers on purchase decisions—"a central topic of psychological economics"—with special reference to the research design (Katona) and the sample survey (Mueller). They are mainly concerned with "the kind and extent of deliberation that accompanies the purchase process," and with "the specific conditions that give rise to careful deliberation."

Ruby T. Norris reports on a field study of house purchases in the New London (Connecticut) area between mid-August 1952 and mid-April 1953—on reasons for buying, alternatives considered, how the house bought was located, how intensively it was looked for, and what the buyers wanted but did not get. The results bring out the wide diversity of buyers' attitudes, divergencies between volunteered opinions and responses to leading questions, and differences between the buyers' judgments and those of the interviewers.

The other two major papers, concerned with living as well as with buying and consuming, are stimulating, even provocative. William H. Whyte, Jr., of *Fortune's* editorial staff, illuminatingly analyzes "the new suburbia" as represented by Park Forest (near Chicago), a "filiarchal" "city of permanent impermanence" displaying "extraordinary homogeneity" and an increasingly communal way of life. Nelson M. Foote explores "The Autonomy of the Consumer," by which he means "the consumer's self-determined use of his sovereignty, his utilization of the opportunity to create his own style of spending." He finds this autonomy worth "cultivating" by the researcher and his employer. But he mainly presents ten challenging research hypotheses relating specifically to what he considers the "new era" that Americans have entered—in which real income will rise chiefly through technical improvements without exertion or self-denial.

A final group of brief papers treats of technical problems in measuring consumer preferences. The Appendix contains a statement about the Committee, summary minutes of its first two annual conferences held in September 1952 and 1953, a subcommittee report on research program, and a short Bibliography on Consumer Behavior.

Economists are increasingly recognizing the importance of consumption in the United States and other advanced economies. Though it has been studied from many standpoints, consumption has so many aspects that our understanding of it is all too superficial and inadequate. Now the American consumption level has risen far above that of 1929, which W. H. Lough discussed in his *High-Level Consumption* . . . (1935), and there is serious talk of "doubling our standard of living" in 25 years or so. Whatever their individual bias, economists of many specialties should therefore welcome the contributions of this

new interdisciplinary body seeking to promote empirical studies of consumer behavior with a view to better understanding of the future.

Economics in General Education. Edited by JAMES GEMMELL, SEYMOUR HARRIS, and S. P. MCCUTCHEN. (New York: Joint Council on Economic Education. 1954. Pp. 151.)

In late summer, 1954, the Joint Council on Economic Education sponsored a conference of economists, educators and administrators of schools of education to discuss the role of economics in general education. The proceedings of this conference have been published under the title given above.

The Joint Council on Economic Education is "a non-profit educational organization created to assist school systems and teacher educating institutions in improving the quality of social and economic education through curriculum research, workshops, seminars, in-service education programs and the preparation of materials for teachers and pupils" (cover page). From the time of its organization in 1948, the Council has carried on a varied program of activities, including a sponsoring role (in cooperation with various colleges and universities) in some 120 workshops in economic education for public school teachers.

The publication here under review is made up of summaries of various papers presented or developed at last summer's conference. The Part I papers deal with such general issues as the importance of economic understanding in a free society (Roy Price, Syracuse University), the nature of economic understanding (Ben Lewis, Oberlin College), the main steps in economic analysis and the relationship of analysis and policy (Seymour Harris, Harvard University), and major issues in economic education (Lewis Wagner, Iowa State).

The Part II papers deal with the organization of college courses in economics. The first is a committee report on the terminal course in economics, including an analysis of the aims and organization of a terminal course and a brief review of several existing or proposed course organizations. The second is a report of a similar study of the interdisciplinary course.

The Part III papers deal with suggestions for the treatment of particular topics in the secondary schools. The first presents a suggested frame of reference for the teaching of economics in the secondary schools (Arno Bellack, Teachers College, Columbia University). The second is an outline of how the functioning of the economy might be presented, using the problem of unemployment as a point of departure (E. T. Weiler, Purdue University, and Glenn Ogle, director of the St. Louis Regional Council on Economic Education). The third is similar to the second, except that the point of departure is agriculture (James Calderwood, Committee for Economic Development). The fourth follows the same pattern, with the consumer as the point of departure (Persia Campbell, Queens College). The fifth paper is a brief description of an historical approach to a study of inflation (Seymour Harris). The sixth is a suggested technique for developing (through class participation) an under-

standing of the problems involved in maintaining economic stability (Lawrence Senesh, Joint Council on Economic Education). The final paper in this section presents an illustration of what a teacher must know if he is to do an effective job of conveying an understanding of the issues in the area of income distribution (Lewis Wagner and C. C. Trillingham, Superintendent, Los Angeles County Schools). Part IV contains but one paper, a committee report on the general subject of needed research in economic education.

I would recommend a reading of this publication to all college teachers of economics, particularly to those who have had no contact with the workshops or other activities of the Joint Council. These papers contain no definitive expositions of theory or teaching technique but they do convey the "flavor" of this program in economic education. To those who believe that it is sufficient to develop a small, well-trained cadre of professional economists, to those who question the value of a "little knowledge" in economics, to those who are unconcerned by the growing problem of communication between the professional economist and the layman (including perhaps his own students), to those who look on the professional educators as a hostile, anti-intellectual force in education, these papers present a real challenge. Whether the goals and methods of the Joint Council be right or wrong, here is a group of men trying to do something in economic education which may well be of unique importance. This being the case, an attitude of rigid isolation on the part of most professional economists hardly seems to be appropriate.

TITLES OF NEW BOOKS

Editor's Note: The following list includes titles of French, Spanish and Dutch publications which have been supplied, respectively, by Jean-Marcel Jeanneney of the Fondation Nationale des Sciences Politiques, Paris, Victor L. Urquidi, Director of *El Trimestre Económico,* Mexico, D.F., and P. J. Verdoorn, of the Centraal Planbureau, the Hague, correspondents of the *Review.*

Economic Theory; General Economics

ALLAIS, M. *Les fondements comptables de la macroéconomique—les équations comptables entre quantités globales et leurs applications.* Ouvrage publié avec le concours du Centre National de la Recherche Scientifique. (Paris: Presses Univ. de France. 1954. Pp. 91. Fr. 900.)

BARKER, C. A. *Henry George* (New York: Oxford Univ. Press. 1955. Pp. xvii, 696 $9.50.)

CLAY, H., ed. *The inter-war years and other papers. A selection from the writings of Hubert Douglas Henderson.* (New York: Oxford Univ. Press. 1955. Pp. xxviii, 445. $6.75.)

CONGARD, R. P. *La demande et le monopole* (Paris: Sté. d'Edit. d'Enseignement Supérieur. 1954. Pp. 384. Fr. 2200.)

FISHER, I. *The theory of interest—as determined by impatience to spend income and opportunity to invest it* Reprints of Economic Classics. (New York: Kelley and Millman. 1954 Pp. xxi, 566 $8 50.)

FOWLER, C. B., GRIFFIN, J. I., COHEN, J. B., CROPSEY, J., GREENWALD, W. I., and SETHUR, F. *Economic handbook—a visual survey* (New York: Thomas Y. Crowell. 1955 Pp. ix, 246 $2 45.)

A graphical presentation of sixty aspects of the economy, accompanied by statistical tables, short descriptive comments, and questions—designed for supplementary use in the basic course.

FRIEDRICH, C. J and GALBRAITH, J K., ed. *Public policy—a yearbook of the Graduate School of Public Administration, Harvard University* Vol. V (Cambridge. Grad School Pub. Admin., Harvard Univ. 1954. Pp vii, 420 $5)

FRITSCH, B. *Die Geld-und Kredittheorie von Karl Marx—Eine Darstellung und kritische Würdigung.* Staatswissenschaftliche stud. 17. (Zurich: Polygraphischer Verlag 1954. Fr. 16.65.)

GALBRAITH, J. K. *Economics and the art of controversy.* (New Brunswick: Rutgers Univ Press. 1955. Pp v, 111. $2 50)

GHOSH, S. K. *Trends in economic thinking.* (Calcutta: Author, 15 Mahendra Road. 1953. Pp. 57. Rs. 2/-.)

GLANSDORFF, M *Théorie générale de la valeur et ses applications en esthétique et en économie.* Inst. de Sociologie, Solvay Collection Soc. Gen. et Phil. Soc (Brussells: Les Editions du Parthenon S P.R L. 1954. Pp. 324.)

HARRIS, S. E. *John Maynard Keynes—economist and policy maker.* (New York: Charles Scribner's Sons. 1955. Pp xiv, 234 $3)

HARWOOD, E. C. *Reconstruction of economics* Including papers by M Brodbeck and R. S. Rudner. (Great Barrington, Mass.: Am. Institute for Econ. Research. 1955. Pp. 110 $1.)

The principal author suggests in his introduction that a more appropriate title might be something like the following: "What, in principle, is wrong with economics as it is taught and practised today; what should be done about the situation; how might men

be trained to do the job; and, what aspects of the task should have their first attention?"

Apart from three book reviews, which were published earlier by the same Institute, and apart from a statement of the Institute program, the essays are essentially concerned with the philosophy and methodology of the social sciences, and economics in particular.

JAMES, É. *Histoire de la pensée économique aux XX^e siècle.* Vol. II, *Après la 'Théorie générale' de J. M. Keynes (1936).* (Paris: Presses Univ. de France. 1955. Pp. 403. Fr. 1200.)

A supplement to this volume *Annexe aux problèmes d'économie internationale* by J. Meiller (59 pp.) has also been published by Presses Univ. de France.

JOHNSON, A. *Economic theory.* (London: Frederick Muller. 1954. Pp. 144. 8*s*., 6*d*.)

MAVERICK, L. A. *Productivity—a critique of current usage.* (Carbondale, Ill.: Lewis A. Maverick. 1955. Pp. 30. 50¢.)

MENDES-FRANCE, P. and ARDANT, G. *La science économique et l'action.* (Paris: Julliard. 1954. Pp. 256. Fr. 600.)

MENICONI, F. *Theorie des Einkommens.* Staatswissenschaftliche stud. 18. (Zurich: Polygraphischer Verlag. 1954. Pp. 328. Fr. 19.60.)

PAPI, G. U., ed. *Teoria e politica dello sviluppo economico* Instituto di Economia e Finanza pub. (Milan: A. Giuffrè. 1954. Pp. 567. L. 3000.)

PAULSEN, A. *Neue Wirtschaftslehre. Einfuhrung in die Wirtschaftstheorie von John Maynard Keynes* und *die Wirtschaftspolitik der Vollbeschäftigung.* 3d ed. (Berlin and Frankfurt aM : Verlag Franz Vahlen GmbH. 1954. Pp. xi, 387. DM 18.80.)

REYNAUD, P.-L. *La psychologie économique.* (Paris: M. Rivière. 1954. Pp. 260. Fr. 700.)

ROTHSCHILD, K. W *The theory of wages* (New York· Macmillan. Oxford: Basil Blackwell. 1954. Pp viii, 178. $2.75.)

SCHOUTEN, D B J. *De dynamiek van het kapitalisme* (The dynamics of capitalism). (Leiden: Stenfert Kroese. 1954. Pp. 27. *f.* 1 50.)

Swarup, R. *Communism and peasantry. Implications of collectivist agriculture for Asian Countries* (Calcutta: Prachi Prakashan [1954] Pp. 194. $5.)

"This book tries to understand communism from an Asian standpoint. It tries to understand the ways in which communism is working out its strategy of domination of Asia, the slogans and sectors of population it uses in this process." (From the author's preface.)

Trivedi, A. B. *Post-war Gujarat—an economic survey after World War II.* (Bombay: A. B. Trivedi, Khalsa College. 1949 Pp x, 289. Rs 19/8)

Van der Valk, H. M. H. A. *The economic future of Canada.* Originally published in Dutch (New York and Toronto: McGraw-Hill 1954. Pp. xiv, 206. $4 75.)

Wadia, P. A and Merchant, K. T *Our economic problem* 4th ed. (Bombay: New Book Co. 1954 Pp. xvii, 757. Rs. 8/)

El desarrollo económico del Ecuador U.N. pub. 1953 II G.5. (México: Naciones Unidas, Comisión para América Latina 1954 Pp. xvi, 218)

An over-all survey of the Ecuadorian economy and its development possibilities. This study has not been issued in English

El desarrollo económico de México Cursos de invierno 1951-52 (México: Escuela Nacional de Econ , Univ. Nacional Autónoma de México. 1952 Pp 272)

Twelve essays by leading Mexican economists on various aspects of Mexico's economic development.

Development of technical assistance programs Prepared by the Subcommittee on Technical Assistance Programs of the Senate Committee on Foreign Relations, 83d Cong., 2nd sess. (Washington: Supt. Docs 1954. Pp. 129)

The economic development of Nigeria Report of a mission organized by the Internat. Bank for Reconstruction and Development at the request of the governments of Nigeria and the United Kingdom. (Baltimore: Johns Hopkins Press. 1955 Pp. xxii, 686 $7.50)

Foreign capital in Latin America U.N pub. 1954 II G 4. (New York: Columbia Univ. Press. 1955. Pp. vii, 164 $1.75)

Ideology and reality in the Soviet system Proceedings of the American Philosophical Society, November 1954. (Philadelphia. American Philosophical Society. 1955. Pp. 38. $1.)

Among the papers is one on "Economic Aspects" by C. B. Hoover.

The Irish pound—1797-1826. A reprint of the report of the Committee of 1804 of the British House of Commons on the condition of the Irish currency. With selections from

the minutes of evidence presented to the committee and an introduction by Frank Whitson Fetter. (Evanston: Northwestern Univ. Press. 1955. Pp. 136.)

Potential economic growth of the United States during the next decade. By the Joint Committee on the Economic Report, 83d Cong., 2nd sess. (Washington: Supt. Docs. 1954. Pp. 35.)

Rehabilitation and development of agriculture, forestry, and fisheries in South Korea. Prepared for UNKRA by a mission selected by the FAO. (New York: Columbia Univ. Press. 1954. Pp. xviii, 433. $8.50.)

Report on the economic situation in Latin America. Prepared for the Internat. Development Advisory Board. (Washington: For. Operations Admin. 1954. Pp. 216.)

Report on the sample survey of Ceylon's consumer finances conducted in May, 1953. (Colomba: Dept. Econ. Research, Central Bank of Ceylon. 1954. Pp. ix, 75. 50¢.)

Toekomstige ontwikkeling van Nieuw-Guinea (The future development of New Guinea). Vols. I and II. Government committee report. (The Hague: Staatsdrukkerij. 1953. Pp. 363.)

Trends in economic growth—a comparison of the western powers and the Soviet bloc. A study prepared for the Joint Committee on the Economic Report by the Legislative Reference Service of the Library of Congress. (Washington: Supt. Docs. 1955. Pp. xiii, 339.)

"The purpose of this report is to summarize the essential known facts bearing upon the comparative rates of economic growth of the United States and independent Europe, on the one hand, and of the Soviet Union and the captive states on the other. . . . The study examines the changes in total economic activity, in the availability of resources, in structure and organization, and in the economic interrelations of these countries over the period 1938 through 1953. It indicates outstanding current problems and, where possible, the orders of magnitude of probable growth to 1970." (From the letter of transmittal by G. W. Ensley, staff director.)

Statistics and Econometrics

Hartkemeier, H. P. *Elementary statistical analysis.* (Dubuque: Wm. C. Brown Co. 1952. Pp xxiv, 484. $6)

Klein, L. R. and Goldberger, A. S. *An econometric model of the United States, 1929-1952.* Contrib. to econ. analysis vol. IX. (Amsterdam: North-Holland Pub. 1955. Pp. 138. $3.75.)

Marschak, J. *Three lectures on probability in the social sciences.* Cowles Commission papers, new ser. no. 82. (Chicago: Cowles Commission for Research in Econ., Univ. of Chicago 1954. Pp 55.)

Theil, H. *Linear aggregation of economic relations.* Contrib. to econ. analysis VII. (Amsterdam: North-Holland Pub. 1954. Pp. xi, 205 $5.)

Tinbergen, J. *Centralization and decentralization in economic policy.* (Amsterdam: North-Holland Pub. 1954. Pp. viii, 80. $1.80.)

Les statistiques de prix en France et en divers pays étrangers. Pub. de l'I.N.S.E.E. (Paris Presses Univ. de France. 1954. Pp. 420. Fr. 1000)

Economic Systems; Planning and Reform; Cooperation

Brand, W. *Het streven van de economisch onontwikkelde landen naar een hogere levensstandaard* (The pursuit of a higher standard of living of underdeveloped areas). (Leiden: Stenfert Kroese. 1954. Pp. 240. *f.* 12.00.)

Rojas Coria, R. *Tratado de cooperativismo mexicano.* (México: Fondo de Cultura Econ. 1952. Pp. 792.)

A comprehensive work on the Mexican cooperative movement by a leading researcher.

VAN DEN BERG, M. *Enige aspekte van die invloed van ekonomiese navorsing op makro-ekonomiese beleid in Nederland en die Verenigde Koninkrijk gedurende 1945-52* (The influence of economic research on macro-economic policy in the Netherlands and the UK). (The Hague: Uitgeverij Excelsior. 1955. Pp. 115. Available on request at the Central Planning Bureau, The Hague.)

National Income and Social Accounting

GOLDSMITH, R. W. *A study of saving in the United States*. Vol. I, *Introduction; Tables of annual estimates of saving 1897 to 1949*. Vol. II, *Nature and derivation of annual estimates of saving 1897 to 1949*. (Princeton: Princeton Univ. Press. 1955. Pp. xxx, 1138; xxiv, 632. $30 for both.)

JOHNSON, J. L. *Income in Kentucky—county distributions by amount, by type, and by size*. (Lexington: Univ. of Kentucky Press. 1955. Pp. xxii, 310. $4.50.)

Business Fluctuations; Prices

BROWN, A. J. *The great inflation 1939-1951*. Issued under the auspices of the Royal Inst. Internat. Affairs. (New York. Oxford Univ. Press. 1955. Pp. xiv, 321. $4.80.)

MALACH, V. W. *International cycles and Canada's balance of payments 1921-33*. Can. stud. in econ. no. 1. (Toronto: Univ. of Toronto Press. 1954. Pp. vii, 154. 12*s*.)

MEYER, F. V. *Inflation and capital* (Cambridge: Bowes and Bowes. 1954. Pp. 75. 12*s*., 6*d*.)

MIETH, W. *Das Akzelerationsprinzip*. Volkswirtschaftliche Schrift. no. 14. (Berlin: Duncker and Humbolt. 1954. Pp. 118. DM 8 80.)

Business and economic forecasting—tools in making business decisions. Report of the Committee on Econ Policy. (Washington: Chamber of Commerce of the U.S. 1954. Pp. iv, 30 50¢)

January 1955 Economic Report of the President. Hearings before the Joint Committee on the Economic Report, 84th Cong, 1st sess, January and February 1955. (Washington: Supt Docs. 1955. Pp ix, 1267.)

Short-term economic forecasting. Studies in income and wealth. Vol XVII By the Conference on Research in Income and Wealth. (Princeton: Princeton Univ. Press, for the Nat. Bur. Econ. Research. 1955. Pp xi, 506 $7.50.)

Money and Banking; Short-Term Credit; Consumer Finance

COPEMAN, G. H. *Leaders of British industry—a study of the careers of more than a thousand public company directors.* (London: Gee. and Co. 1955. Pp. 173. 15 *s.*)

DIAMOND, S. *The reputation of the American businessman.* (Cambridge: Harvard Univ. Press. 1955. Pp. 209. $4.)

An analysis of journalistic comment elicited by the deaths of six famous American businessmen: Stephen Girard, John Jacob Astor, Cornelius Vanderbilt, J. Pierpont Morgan, John D. Rockefeller, and Henry Ford. An underlying assumption is the following: "In any highly complex society, the media of mass communications indicate acceptable forms of behavior, suggest that deviance from those forms is to be deplored, lend authority to certain persons within the community, and give weight to some opinions rather than others." (From the Introduction, p. 3.)

NOTES

A nominating committee consisting of Ewald T. Grether, William Haber, Harlan L. McCracken, Aryness Joy Wickens, Harold F. Williamson, and Edwin G. Nourse, chairman, has submitted the following slate of nominees for 1956 officers of the American Economic Association:

President: Edwin E. White, University of Wisconsin

Vice President:

Richard B. Heflebower, Northwestern University
Paul T. Homan, University of California, Los Angeles
Fritz Machlup, Johns Hopkins University
Ralph A. Young, Board of Governors, Federal Reserve System

Executive Committee:

Henry B. Arthur, Swift & Co., Chicago
William J. Fellner, Yale University
Walter E. Hoadley, Jr., Armstrong Cork Co., Lancaster, Pa.
Richard A. Musgrave, University of Michigan

Representative of Social Science Research Council:

John P. Miller, Yale University

The annual meeting of the Association will be held at the Hotel Commodore, New York, December 28-30, 1955.

PUBLICATIONS

The Graduate School of the University of the East, Manila, Philippines, began publication, in 1954, of a quarterly journal entitled *Economic Research Journal*, devoted mainly to economic problems of the Philippines

Yiddish Scientific Institute—Yivo. The Commission on Research of the Yiddish Scientific Institute, 535 West 123rd Street, New York 27, N.Y., as part of its regular program, is compiling a continuing bibliography of social scientific studies in all aspects of American Jewish life. Scholars and communal agencies are requested to forward information about recent or current studies, published or unpublished

INFORMATION BUREAU FOR AMERICAN SCIENTISTS VISITING GERMANY

The "Atlantik-Brücke," a group of private citizens interested in furthering better understanding of Germany in the United States and vice versa, has established an Information Bureau. The bureau provides, particularly to visiting Americans, information on German research institutes, universities, libraries, scientists, their publications and their research in progress in the field of German social sciences Interviews with experts on economic, social or political questions will be arranged on request. Communications should be addressed to the Information Bureau on German Social Sciences, Hamburg 13, Harvestehuderweg 9.

Death

Victor W. Bennett, chairman of the department of marketing, University of Miami, died in March 1955.

Appointments and Resignations

Henry G. Aubrey is on leave from the research department of the Federal Reserve Bank of New York to serve as economic consultant to the Harvard University's Graduate Faculty of Public Administration team of advisers to the Pakistan Development Board.

James A. Barnes, of Temple University, has been visiting professor of economics at the University of Miami during the academic year 1954-55.

Harold Bierman, Jr., has been appointed assistant professor of accounting in the School of Business, University of Chicago, effective October, 1955.

Gladys Boone, professor of economics and chairman of the Division of Social Studies at Sweet Briar College, has spent sabbatical leave during the second semester 1954-55 at the Institute of Industrial Relations, University of California, Berkeley.

George H. Borts has been promoted to associate professor of economics at Brown University.

Jess W. Brandon has been promoted from assistant professor to associate professor of accounting in the School of Business Administration of the University of Miami.

William N. Breswick has resigned from Southwest Research Institute, San Antonio, to become associate economist at the Phoenix office of Stanford Research Institute.

Donald J. Butterworth has been appointed associate professor of marketing at the University of Florida.

Burnham O. Campbell has been appointed acting instructor in economics at Stanford University.

Alan R. Cerf, of Stanford University, has accepted an appointment as assistant professor of accounting in the School of Business Administration, University of California, Berkeley.

Lester V. Chandler has been appointed chairman of the department of economics and sociology at Princeton University, replacing Richard A. Lester who is to be on leave next year.

H. W. Cordell, of Ohio State University, has been lecturer in marketing at the University of Florida in the second semester of the past academic year.

Virgil D. Cover, on leave from Syracuse University until September 1956, is visiting professor of Business Administration at the University of Rangoon, Burma, on a Ford Foundation appointment.

Richard M. Cyert has been promoted to associate professor of economics at Carnegie Institute of Technology

Frank Dunbaugh has been promoted to associate professor of marketing in the School of Business Administration of the University of Miami.

Warren W. Eason, of Johns Hopkins University, has accepted an appointment as assistant professor of economics and bicentennial preceptor at Princeton University.

Corwin D Edwards, visiting professor at the University of Virginia, has accepted an appointment as professor of government and business in the School of Business, University of Chicago, effective October 1955. In April of this year he delivered four Merrill Foundation lectures in Cleveland under the joint sponsorship of Western Reserve University and Case Institute of Technology.

Gertrud G. Edwards has been visiting lecturer in economics at Sweet Briar College in the past semester.

Denis A Flagg has resigned from the department of economics, University of California, Berkeley, to accept a position at San Diego State College.

Edward J. Fox, of the University of Western Ontario, has been appointed visiting professor of marketing for another year in the School of Business Administration, University of Miami.

Heinrich Friedlaender, formerly professor of economics, Harpur College, State University of New York, is now consultant, Frankfurt/Main, Germany.

Eirik Furobotn has been appointed instructor in economics at Rensselaer Polytechnic Institute.

Charles C. Gersna, of the University of Michigan, has been appointed interim instructor of marketing at the University of Florida.

Frederick H. Harbison, of the University of Chicago, has accepted an appointment as professor of economics and director of the Industrial Relations Section at Princeton University effective September 1955.

George R. Hawkes has resigned as lecturer in the School of Business Administration, University of California, Los Angeles, to accept a position with the accounting firm of Price Waterhouse & Co.

Everett D. Hawkins, of Mount Holyoke College, was visiting lecturer in economics at the University of Massachusetts in the spring term.

William G. Heuson has been promoted from assistant professor to associate professor of finance in the School of Business Administration, University of Miami.

John W. Hooper has been appointed acting instructor in economics at Stanford University.

Marshall Howard, of the University of Massachusetts, has been visiting lecturer in economics at Smith College in the past academic year.

John Ise, who has been teaching economics at the University of Kansas since 1916, retires this year.

Neil H. Jacoby, who has been on leave to serve as a member of the Council of Economic Advisers to the President, has returned to his post as dean of the School of Business Administration, University of California, Los Angeles.

Myron L. Joseph has been promoted to associate professor of economics at Carnegie Institute of Technology.

Alfred E. Kahn has been promoted to professor of economics at Cornell University.

Eloise Kimmelman has been promoted from assistant professor to associate professor of accounting in the School of Business Administration, University of Miami.

E. A. Kincaid, of the University of Virginia, has been lecturer in finance at the University of Florida in the spring term.

E. R. Kuchel has been promoted from instructor to assistant professor in the department of economics of the University of Wyoming.

Leland C. Lehman, of Denison University, has accepted a research position with the Federal Reserve Bank of Minneapolis while on sabbatical leave.

Clarence D. Long has returned to Johns Hopkins University after serving with the Council of Economic Advisers as senior staff member in charge of labor matters.

Fritz Machlup, of the Johns Hopkins University, will be in Kyoto, Japan, until August where he is serving as visiting professor at Kyoto University and Doshisha University and as director of the Kyoto American Studies Seminar.

Edwin Mansfield, currently in England as a Fulbright scholar, will be assistant professor of economics next year at Carnegie Institute of Technology.

Julius Margolis has resigned from Stanford University to accept a position as lecturer in economics at the University of California, Berkeley.

Henry E. Mattox has been appointed instructor in economics at the University of Mississippi.

Alexander Melamid has been appointed assistant professor of economic and political geography in the Graduate Faculty of Political and Social Science of the New School for Social Research.

Hyman P. Minsky has been promoted to associate professor of economics at Brown University.

George Moss, who is at present on the accounting staff of the University of San Francisco, will return to the University of Miami as assistant professor of accounting in the fall.

John H. Mudie, of the University of Texas, has been appointed acting assistant professor of economics at Texas A & M College.

Eastin Nelson has been granted leave of absence from the University of Texas to accept a visiting lectureship in economics at San Carlos University, Guatemala City, Guatemala.

Ruth Bilsky Norr has been instructor in economics at Wellesley College in the second semester of the current academic year.

Robert T. Patterson, formerly of New York University, is joining the staff of Claremont Men's College as associate professor of public finance for the fall semester 1955-56.

Gaston V. Rimlinger has been appointed instructor in economics at Princeton University.

George W. Robbins has been named associate dean in the School of Business Administration, University of California, Los Angeles.

Merrill J. Roberts has been appointed professor of economics at the University of Florida.

Robert M. Robinson, of the University of California, Berkeley, has accepted a position at Sacramento State College.

Ralph L. Sackett has been appointed chairman of the department of marketing in the School of Business Administration, University of Miami.

Irving Schweiger has been appointed associate professor of business administration in the School of Business, University of Chicago.

Howard Shuman has resigned from the University of Illinois to accept a position as legislative assistant on the staff of Senator Paul H. Douglas.

Alfred G. Smith, Jr., has been promoted from associate professor to professor of economics in the department of economics at the University of South Carolina.

F. DeVere Smith has been promoted from associate professor to professor of economics in the School of Business Administration, University of South Carolina.

Victor E. Smith, of Michigan State College, has spent this year at Cambridge University as the holder of a faculty fellowship from the Fund for the Advancement of Education.

Thorn K. Snyder has resigned from Purdue University to take a position with the Arabian American Oil Company in Saudi Arabia.

Milton H. Spencer has resigned from De Paul University to accept an appointment as associate professor in the School of Business Administration at Wayne University.

Harry Stark has been promoted from lecturer to assistant professor of economics in the School of Business Administration of the University of Miami

George A. Steiner has been granted a year's leave of absence from the University of Illinois to serve as senior economic adviser in the development planning department of Lockheed Aircraft Corporation, Burbank, California.

Herbert E. Striner has resigned from the National Science Foundation as study director for industrial research to accept an appointment with the National Planning Association.

James MacD. Terrell has been appointed instructor in economics at Brown University.

Proctor Thomson, formerly of the University of Chicago, is joining the staff of Claremont Men's College as associate professor of economic education for the fall of 1955-56.

Otto von Mering has retired from the department of economics at Tufts College.

Harry I. Warner has been promoted from lecturer to assistant professor of accounting in the School of Business Administration, University of Miami

Harold L. Wattel has been granted leave from Hofstra College to serve as economic consultant to the Consumer Counsel to the Governor of New York State.

H. Lawrence Wilsey has been appointed chief of the China Division of the Foreign Operations Administration, Washington, D C.

Alvin B. Wooten has resigned from Texas A & M College to take a position with the Texas Agricultural Extension Service.

James S. Worley has been appointed instructor in economics at Princeton University.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Private and public finance: Ph.D. with emphasis in private and public finance for a large coeducational Catholic university in the Midwest, beginning in fall, 1955. Prefer man with some institutional and some teaching experience. P170

Research in economics and investments: Large Eastern company needs a versatile research analyst to work on a wide variety of problems in an established economic-investment research unit. Requirements: At least the M.A., M.S., or M.B.A., preferably Ph.D.; good background in economics with specialization in monetary, investment, or insurance fields; the ability to write well; age not over 35; good personal appearance. This is a research position, but the man must also be able to make a favorable impression on our line executives in both written and oral presentations of his research findings. P171

International travel opportunity: The Council on Student Travel invites applications for short-term employment as educational directors on trans-Atlantic ships. Required: educators from the following fields: cultural anthropology, art history, international relations and economics, group work, language, philosophy, recreation, sociology. Conversational ability in one or more of the following: French, German, Greek, Italian. Ability to organize extensive educational program with the help of passenger volunteers. From March to December, 1955, the program will be conducted by the Council for students, tourists and migrants traveling aboard two large passenger ships belonging to one of the major lines. These ships sail regularly from New York to European and Mediterranean ports. Job assignments vary from one round-trip sailing to periods of 3-5 months. Compensation for these longer periods of service will be regular salary. For a single round-trip sailing, full or partial passage, depending upon job requirements. All positions allow for time abroad. For further information, application form, write to: Council on Student Travel, (0-1), 179 Broadway, New York 7, N.Y. REctor 2-0936.

Marketing, management, real estate: School of Business needs assistant professors in above fields, beginning September, 1955. Terminal degrees preferred. School located in Midwest. In replying, please include personal history, education, and employment experiences. P173

Economic principles and theory: Instructor or assistant professor, Catholic co-educational college in large midwestern center. Master's degree required. Salary four to five thousand, depending upon the qualifications. No objections to outside work. P174

Business administration: Instructor or assistant professor, small Catholic co-educational college in large metropolitan, midwestern center. Salary four to five thousand depending upon qualifications. Should be able to teach management and general business subjects. Ample opportunity for consultation or other outside work if desired. P175

Teaching position in economics: The University of Puerto Rico has a position available for a young man, preferably single, having at least an M.A. degree in economics. Please write to Dr. William H. Beckwith, Director, Division of General Studies, College of Agriculture and Mechanic Arts, University of Puerto Rico, Mayaguez, Puerto Rico.

Economists Available for Positions

Industrial surveys, personnel management, market research, international economics: **Man, 36, Ph.D. Extensive experience with industry, government, advertising, foreign intelligence; various teaching positions; publications; supervisory, editorial, public relations, and lecturing experience. Several foreign languages. Presently employed in New York City headquarters of an international organization. Interested in more responsible position with industrial, commercial company or large university. E450**

Business cycles, economic development, public control, transportation: Man, 35, M.A., Ph.D., University of Pennsylvania. Nine years of teaching experience at leading institutions; 5 years in industry. Broad familiarity with manufacturing and transport industries; good publication record. Desires teaching and/or research. E528

Economic principles, labor, economic thought, economic history, economic systems, corporation finance, marketing, money and banking: Man, A.M., Northwestern University, Ph.D., Yale University. Fifteen years of economics teaching experience; government experience as price economist. Broad social science background. Project in American economic field completed. Available in June or September. E536

Economic and financial history, economic theory, public finance, money and banking, labor economics, corporation finance, investments and allied subjects: Man, 40, married, Ph.D. Now teaching at large Eastern university. Interested in teaching position or perhaps a combination of teaching and some administrative work. E542

Economics of the firm, public utilities, principles, value and distribution theory, public finance, government and business, business cycles: Man, 33, married; M.A., University of Toronto, Ph.D., University of Wisconsin. Teaching since 1945; broad occupational experience, veteran, fellowships, articles in preparation. Desires teaching or position as economist for large firm. Available in June or September, 1955. E544

Public finance, price theory, national income analysis, social control, money and banking, economic principles: Man, 30, married; Ph.D., summer, 1955. Two years of experience in a large state university teaching mainly advanced courses; 2 years of experience as an economist specializing in the analysis of prices and national income for a research division of the federal government. Currently teaching. Desires teaching and/or research position. E545

Labor economics, industrial relations, economic analysis, money and banking: Man, 36, Ph.D., University of Chicago. Experience includes graduate and undergraduate teaching, top-level federal government position, university research, and industry. Interested in teaching and research. E549

Economic history, business history, insurance history: Man, 36, Ph.D., New York University. Fourteen years of governmental experience, including those of an advisory and administrative nature; 1 year of teaching experience. Has considerable counseling experience. Desires research, writing, or teaching position. Interested especially in collge or university teaching position. Of especial usefulness to life insurance companies as research assistant or historian. E553

Economics, statistics, corporation finance, investments, accounting, tax accounting, marketing: Man, 40, married; B.A., M.A., Ph.D. requirements completed except the dissertation. Ten years of teaching experience. Desires teaching or investment position. E557

Comparative economic systems, principles, corporation finance, public finance, labor, economic history, business law, constitutional law: Man, middle age; M.A., LL.B., and course requirements in economics for Ph.D. recently completed at a Big Ten university. Ten years of legal and business and 6 years of teaching experience, including 3 years at university level. Is primarily interested in the stimulating type of undergraduate teaching. Desires a teaching position. Available in June or September, 1955. E558

International trade, money and banking, investments, market research, labor economics: Man, married; Ph.D. expected this spring. Three years of university teaching numerous fields in economics; 7 years of government research experience in cost and statistical analysis, interindustry relationships, price studies, and labor relations. Interested in teaching position or opening in private industry in management, sales engineering, or foreign trade. Available immediately. E562

International trade, comparative economic systems, urban land economics, marketing, history of economic thought, public finance, money and banking, economic history of Europe: Man, Ph.D. Research fellowships; 7 years of university and college teaching; 4 years of research in federal government. Experience as consultant; multilinguist; extensive foreign travel. Desires teaching or research position. E563

Economic theory, statistics, accounting, money and banking, private and public finance, mathematical economics, international trade: Man, 35; B.S., M.A., Harvard, plus 2 years of graduate study on economic theory and statistics. Now assistant professor of economics and special lecturer of statistics; 6 years of successful college teaching experience. Other experiences include federal government position, university and industry research. Desires better teaching position or responsible statistical research position. E564

Economic history, history of economic thought, economic theory, money and banking, business cycles, international trade and economics, economic geography, corporation finance, investments, marketing: Man, 30, Ph.D., Rotterdam. Has some teaching, industrial, and marketing experience and excellent references. Desires teaching, research, or advisory position in California (San Francisco area) Arriving June, 1955. E565

Marketing research, salesmanship, retailing, business cycles, money and banking, principles of economics, principles of marketing, labor relations, personnel administration, business organization and management, American industry and economic geography, foreign trade: Man, 32, married; B.A., M.B.A., Ph.D. course and written requirements completed at New York University (Graduate School of Business Administration). President of small business 2 years; former assistant professor of economics at a large Southwestern college; 6 years of college and university teaching plus practical business background. Interested in position as teacher, in administration, or with industry. E568

Labor economics, industrial relations, advanced economic theory, monetary theory, history of economic doctrines, sociological theory, methodology: Man, 40, married, Ph.D. Twelve years of teaching experience on both the graduate and undergraduate levels; publications. Seeks teaching and/or research. Available in September, 1955. E570

Public regulation of business, public utilities, transportation, communication: Man, Ph.D. Teaching position desired in June or September, 1955. E571

Investment analysis, auditing, budgeting, business finance: Man, 51, J.D. Twelve years of experience in banking, credit and investment transactions; 5 years of experience in auditing large European organizations; 15 semesters of teaching experience as a professor in a fully accredited university in the U.S. Desires position as an investment analyst, controller, or treasurer. Also interested in teaching position. Available in June, 1955. E572

Beginning economics, economic geography, money and banking, credit, retailing, marketing, public utilities: Man, B.S., M.S., plus year of advanced study. Thirty years of experience in teaching and research work; 28 years of teaching in one institution. Being retired under faculty service ruling. Available for part-time, visiting, or supply instructor. Available in July or September. E573

Economic principles, money and banking, public finance, corporation finance, investments, business cycles, international economics: Man, 37, single; B.S., M.A., requirements for Ph.D. completed and dissertation in progress. Ten years of business experience in commercial banking and insurance underwriting; 2 years of teaching experience at outstanding midwestern schools; currently chairman of department of economics and business at a leading midwestern college. Desires a change to a better position offering greater opportunities for research and development. Stimulating teacher and public speaker. Partial to Southwest (Arizona) or West Coast location. Available in June, 1955. E574

Economics of Far East, underdeveloped areas, international trade, money and banking, principles, price and income theory, cycles: Man, 32, married; Ph.D. dissertation in progress. Eight years of teaching experience at state universities; 2 years as chief economist, stabilization agency; publications; journalistic background. Now teachng, but welcomes participation in research, teaching, or combination program with attention to Far East and underdeveloped economies. Available on short notice. E575

Business research: Man, 43, married; Ph.D. Industrial and university experience; publications; national convention speaker. Background in statistics, finance, economics, and business administration. Seeks either full-time research or research combined with teaching. E576

Principles, corporation finance, investments, money and banking, American economic history: Man, 56, married. Retired as officer of leading New York bank after 35 years of experience in investments and corporation finance; now completing studies for Ph.D. at Columbia University. Some teaching experience; extensive foreign travel; French and other languages. Desires fall-term teaching position. E577

Economic theory, international trade, marketing, comparative economic systems, public finance, investments, corporation finance: Man, 42; Ph.D. Wide experience in teaching, high-level government service, and private industry. Interested in teaching, research and/or administration. E578

Economic principles, comparative economic systems, labor, economic thought, economic history, corporation finance, money and banking: Man, 29, married; Ph.D. course requirements completed. Two years of research experience; 2 years of teaching; now teaching in midwestern college; several European languages. Available in June or September, 1955. E579

Economic theory and principles, history of thought, public and private finance, and other subjects: Man, under 40, prewar Ph.D. Experience in banking, research, government service. Taught 17 years at every level through Ph.D. program, including most fields in economics and business curriculum, specializing in economic theory; past 7 years at large state university, with permanent tenure. Original contributions to scholarly and popular journals in economic theory, finance, and other fields; pioneering book to be published this summer; three others, including textbook, in progress. Minimum: full professorship. Please state salary. Available immediately. E580

Economics, business administration: Man, 51, married; B.S., M.A., near Ph.D., Chicago. Nineteen years of university and college teaching, much of the time as head of departments of economics and business administration; 5 years of responsible government work as economist, business analyst, or administrative assistant. Wide business experience, selling, sales management, accounting and tax fields; now associate professor of management, California college. Primarily interested in teaching position West or Northwest (preferred). Available in June or September, 1955. E581

"What! No Kitchen Telephone?"

Of all things, Mr. Bridegroom! Surely you don't expect that lovely new bride to get along without a telephone in the kitchen!

Maybe there was a time when one telephone seemed enough, just as one radio and one bathroom and one car seemed enough.

But everybody is used to more comfort and convenience these days. And there's nothing that makes life so much easier as telephones around the home.

In the living room, of course. In the kitchen, conveniently hung on the wall. In the bedroom, to save steps and for added peace of mind both day and night. For the son and daughter who'd like telephones of their own, with separate listings.

Would you like to know more about complete telephone service and how surprisingly little it costs? Just call the business office of your local Bell telephone company.

BELL TELEPHONE SYSTEM

A book that documents the full power and promise of our American economic system

America's Needs and Resources

A NEW SURVEY

A Twentieth Century Fund study by J. Frederic Dewhurst and Associates

▪ Hailed in its original version by *Time Magazine* as "monumental," this completely new survey of America's Needs and Resources is "even more than its predecessor, a basic source book on the American economy . . . a complete and many-sided view." *N.Y. Times Book Review.*

Now this new survey brings up to date, in comprehensive figures, the vast panorama of our past achievements; assesses our present strength; and provides an extremely well-informed look at our future potential to 1960.

▪ With a major focus on the postwar boom, the long range upsurge of the economy, and the significance for the future of our expanding economy, this new volume gives extensive attention to such new factors as technological advances, new products and techniques, welfare, and their effects on American productivity and the economy as a whole.

The present volume is completely revised and rewritten, and expanded by nearly fifty per cent. The result is a guide, source book and reference work that will prove invaluable to every businessman, industrialist, economist, sociologist, political scientist—anyone interested in America's economic strength and economic future.

new books from the

UNITED NATIONS

GROWTH and STAGNATION in the EUROPEAN ECONOMY

In this analysis Professor Ingvar Svennilson of the University of Stockholm examines in detail output, investment, exports, population changes, and market structure and their causal relations to the fluctuations in Europe's economic structure. The period covered—composed of two business cycles of some nine years each set in a long-term perspective—extends back to the beginning of the first World War and up to the outbreak of the second. Wherever possible, however, the data has been extended as far back as 1880 and up to 1950. Professor Svennilson devotes particular attention to what he considers the main reason for the stagnation between wars—the slowness with which Europe faced the need to make far-reaching transformations in its production and trade. 342 pp. Charts, Graphs, Subject Index. Cloth, $4.50.

ECONOMIC SURVEY of EUROPE in 1954

A concise survey which reconstructs the economic climate of western, eastern, and southern Europe 1953 through December, 1954, with consideration of more long-term issues. Chapter headings include: the economic upswing in western Europe and its background, recent changes in the economies of eastern Europe, economic development in the Soviet Union, problems of regional development in industrial location in Europe, and the structure of the French economy. 315 pp. Charts, Graphs. Paper, $2.50.

STATISTICAL YEARBOOK, 1954

The sixth issue of a comprehensive and authoritative collection of international statistics presented in 179 tables, most of which cover a twenty-year period ending in 1953 and some of which have been brought up to the middle of 1954. The data included covers such topics as: population, manpower, agriculture, industrial production, manufacturing, and internal trade. Tables of conversion factors and alphabetical subject and country indexes are provided. 594 pp. Paper $6.00, cloth $7.50.

EDWARD ALSWORTH ROSS

Secretary of the American Economic Association, 1893

Edward Alsworth Ross was born at Virden, Illinois, on December 12, 1866. He died at Madison, Wisconsin, July 22, 1951. He was left an orphan at the age of eight. At fifteen, he entered the preparatory school of Coe College, Cedar Rapids, Iowa, was graduated from this College in 1886 (LL.D., 1911). After teaching school for two years, he went to Germany, spending a year at the University of Berlin. His next three years were spent at Johns Hopkins University, where he received his Ph.D. degree, with a major in economics and minors in philosophy and ethics. Thereafter he became a member of the faculty of Indiana University for a year, then another year at Cornell University, then seven years at Stanford. This was followed with a five-year professorship at the University of Nebraska. From there he was called to the University of Wisconsin in 1906, where he stayed until his retirement in 1937. It was here that he wrote most of his books and articles on sociology and became recognized as one of the pioneers in that field. He was one of the four sociologists to be elected for two successive terms as president of the American Sociological Society, 1914-15. Ross was elected Secretary at the annual meeting held August 23-26, 1892, at Chautauqua, New York. He was elected to succeed Richard T. Ely, who was at that time moving to the University of Wisconsin and who had delegated most of the secretarial work to Frederick C. Howe, acting as Assistant Secretary. Ross had moved from Johns Hopkins University to Cornell. In September, 1893, he wrote to Jeremiah W. Jenks from Stanford University that owing to illness, he was not able to formulate his Secretary's report and that he "was only too anxious to get rid of the burden of duties and responsibilities which though not heavy in themselves felt rather heavy to [him] then."

FINANCIAL ASPECTS OF ECONOMIC DEVELOPMENT

By JOHN G. GURLEY AND E. S. SHAW*

Economic development is commonly discussed in terms of wealth, the labor force, output, and income. These real or "goods" aspects of development have been the center of attention in economic literature to the comparative neglect of financial aspects. Yet development is associated with debt issue at some points in the economic system and corresponding accretions of financial assets elsewhere. It is accompanied, too, by the "institutionalization of saving and investment" that diversifies channels for the flow of loanable funds and multiplies varieties of financial claims. Development also implies, as cause or effect, change in market prices of financial claims and in other terms of trading in loanable funds. Development involves finance as well as goods.

In the first section below we review briefly the financial manifestations of income generation, spending and saving, investment, and the accumulation of wealth. The second section is concerned with the role of financial institutions or intermediaries in transmitting loanable funds between spending units. The third section suggests that conventional theories of income, interest, and money have given insufficient attention to important reciprocal relationships between real development and financial development, and proposes some theoretical adaptations. The final section is concerned with illustrative implications of our analysis for some aspects, especially the monetary, of economic policy and regulatory techniques.

I. *Finance in the Social Accounts*

Analysis of economic change and development has customarily relied on an abbreviated set of social accounts. This set of accounts reports

* The authors are, respectively, associate professor of economics at the University of Maryland and professor of economics at Stanford University. Both are currently engaged on a research project for the Brookings Institution.

the net worth items of income, consumption, and saving as well as the asset item of investment or wealth accumulation. The accounts omit the financial side of change and development, that is the accumulation of debt and financial assets in their various forms. They are not a complete social balance sheet. One result is that financial analysis, left to its own devices, has been difficult to coordinate with analysis "on the side of goods." Another result, we suspect, is an inadvertent undervaluation by economists of the role that finance plays in determining the pace and pattern of growth.

A. *Deficits, Surpluses, and Balanced Budgets.* It is not difficult, in principle, to design a set of social accounts that does incorporate finance. Final buyers of output, or spending units, may be divided into three groups:

Spending units with *balanced budgets* keep their spending—on consumption, investment, or government goods and services—precisely in balance with income. If they save, they invest a like amount, so that their financial assets do not change relative to outstanding debt including equity claims other than earned surplus.[1] Spending units with *surplus budgets* have an excess of income over spending on goods and services. If they save, their saving exceeds their own investment, so that their financial position improves. Their financial assets increase more or decrease less than their liabilities, and they are thereby suppliers of loanable funds. Spending units with *deficit budgets* permit spending to exceed income.[2] They demand loanable funds, releasing financial assets or issuing debt, so that their financial assets decline relative to the sum of their liabilities and equity other than earned surplus. A complete set of social accounts would report the flows of loanable funds between spending units and the corresponding changes in financial status.[3]

There are financial corollaries following from the *ex-post* identity of receipts and expenditures, of saving and investment, and of surpluses and deficits for the aggregate of spending units. First, loanable funds supplied equal loanable funds acquired. Second, the increase of net

[1] By "debt" and "liability" we mean both the creditor claims and the equity claims that are instrumentalities of external financing.

[2] In 1939 Walter S. Salant proposed that spending units be classified as we propose, so that real change could be explicitly related to financial change. National Bureau of Economic Research, *Studies in Income and Wealth*, Vol. III (New York, 1939), pp. 305-11. Mr. Salant has been most helpful in discussions of this article, but no guilt attaches to him for the consequences.

[3] It may be helpful if our definitions are put more succinctly. Let R be receipts on income account, E expenditures on income account, D any increment in debt, and FA any increment in financial assets. Subscripts b, s, and d refer to type of spending unit (balanced-budget, surplus-budget, and deficit-budget). Then, for any spending unit:

$$E - R = D - FA$$

financial assets for surplus spending units equals the increase of net financial liabilities for deficit spending units. The rise of income and the accumulation of wealth are one aspect of growth: the corollary, where budgets are unbalanced, is the accumulation of debt and financial assets.[4]

An *ex-ante* balance between income and spending, saving and investment, and surpluses and deficits implies *ex-ante* balance between offers of and bids for loanable funds, offers of and bids for financial assets, willingness to incur debt and willingness to hold debt instruments. An equilibrium level of income and wealth is associated with an equilibrium level of debt and its counterpart in financial assets.

B. *Relative Change in Debt, Income, and Wealth.* Accumulation of debt is part of the growth process, but the rate of accumulation is not related by a simple constant to the rise of wealth and income.[5] The proportion of the stock of debt to a community's income appears to depend on three complex factors: (1) the ratio of borrowing to deficits; (2) the ratio of deficits to income; (3) and the rate of change in income. To the degree that the income-wealth ratio is stable, the proportion of the stock of debt to community wealth depends on these same factors. Any variation in the income-wealth ratio becomes a fourth factor affecting the debt-wealth relationship.

The ratio of borrowing to deficits is affected by the manner in which deficits are financed, as we shall see in the next section. It is affected, too, by the desire of spending units to incur debt for other purposes than finance of deficits. These purposes may include acquisition of claims on banks and other financial intermediaries, of claims that give managerial control over other spending units, or of claims that have speculative interest.

The ratio of deficits to income depends in part on such institutional factors as the chronic concentration of investment in some sectors, say

Spending units may be classified as follows:

Balanced-budget	$D_b = FA_b$
Surplus-budget	$D_s < FA_s$
Deficit-budget	$D_d > FA_d$

The flow of loanable funds is $FA_s - D_s = D_d - FA_d$

[4] We neglect various complexities in accounting for finance. For example, we overlook nonuniformity in accounting practices and the resulting imbalance between the records of debtors and creditors. We omit, too, the possibility of transfers of existing real assets, rather than securities, between deficit spending units and surplus spending units.

[5] A particularly helpful discussion of wealth-debt relationships may be found in R. W. Goldsmith, *Financial Structure and Economic Growth in "Advanced" Countries*, (mimeo.), a paper presented to the Conference on Capital Formation and Economic Growth, National Bureau of Economic Research (New York, 1953).

the corporate, and of saving in others, such as the personal sector. Institutional or technical factors that alter the division of labor between savers and investors must affect the proportion of debt to income and wealth. The ratio of deficits to income evidently depends, too, on disturbances in the propensity to spend, by spending units with access to borrowing facilities, on goods regarded by creditors as a suitable basis for lending.

However stable may be the proportion of borrowing to income in any period, the proportion of accumulated debt to income depends on how rapidly income is growing. It is relatively low if income is gaining swiftly, high if income growth is sluggish. The stock of debt changes slowly enough so that variations in the growth rate of income can significantly affect the debt-income relationship.

Whatever the ratio of debt to income, the ratio of debt to wealth reflects variations in the income-wealth ratio. These variations may occur for any of several reasons. For example, income and debt may rise on a wave of spending that does not result forthwith in capital formation.[6] Again, technological factors may alter the capital coefficient at full employment of productive capacity. Or, because of variations in effective demand, productive capacity may be exploited more or less intensively.

II. *Finance and Financial Intermediaries*

A. *Self-Finance, Direct Finance, and Indirect Finance.* Expenditure is self-financed by spending units with balanced budgets. Their consumption is financed from income, their investment from internal savings. If their financial assets and debt do change, the changes are equal. Self-finance continues to be important in the most sophisticated economic system, say in the form of investment out of retained corporate earnings. But over the very long term, the trend has been away from self-finance. Government, business, and consumers alike have come to lean more heavily on external finance.

External finance may take either of two forms, direct finance or indirect finance. Direct finance involves borrowing by deficit spending units from surplus spending units. The former issue debt of their own, *direct* debt. The latter buy and hold financial assets in the form of these direct securities. If spending on capital formation is directly financed, debt tends to accumulate *pari passu* with wealth.

Economic development is retarded if only self-finance and direct

[6] Debt to finance exhaustive spending is sometimes called "dead-weight" debt. We have avoided this term because it suggests, improperly in our view, that such debt is necessarily obstructive in the growth process in contrast with debt that finances expansion of productive capacity.

finance are accessible, if financial intermediaries do not evolve. The primary function of intermediaries is to issue debt of their own, ***indirect*** debt, in soliciting loanable funds from surplus spending units, and to allocate these loanable funds among deficit units whose direct debt they absorb.

When intermediaries intervene in the flow of loanable funds, the accumulation of financial assets by surplus spending units continues to equal the accumulation of debt by deficit units. The rise of intermediaries—of institutional savers and investors—does not affect at all the basic equalities in a complete social accounting system between budgetary deficits and surpluses, purchases and sales of loanable funds, or accumulation of financial assets and debt. But total debt, including both the direct debt that intermediaries buy and the indirect debt of their own that they issue, rises at a faster pace relative to income and wealth than when finance is either direct or arranged internally. Institutionalization of saving and investment quickens the growth rate of debt relative to the growth rates of income and wealth.[7]

B. *Commercial Banks and Competitive Intermediaries.* A monetary system, and especially its commercial banking component, has commonly been the first significant financial intermediary to complicate the simplicity of self-finance and direct finance. Even as late as a half-century ago in this country, the commercial banks offered the predominant escape from self-finance and direct finance.

The role of the banks has been, first, to borrow loanable funds from spending units with surpluses, issuing indirect securities in exchange. These securities have been the currency and deposits that spending

[7] In terms of definitions in note 3 above: Total expenditures (E) = Total finance $(R + D - FA)$. Then self-finance is $R - FA$ and external finance is D, which may be rewritten as D^p to distinguish the debt of spending units from D^i, the debt, aside from equity claims, of financial intermediaries. D^p is direct debt, while D^i is indirect debt. Financial assets, too, may be classified into FA^p, balances in the form of direct debt issued by other spending units, and FA^i or balances in the form of nonequity claims on financial intermediaries. Assuming that no borrowing is done simply to finance accumulation of financial assets, we may describe direct finance in this fashion:

For surplus units FA_s^p = budget surplus
For deficit units D_d^p = budget deficit
For all units combined $FA_s^p = D_d^p$ = budget deficit

And the description of indirect finance is:

For surplus units FA_s^i = budget surplus
For deficit units D_d^p = budget deficit
For financial intermediaries $FA_f^p = D_f^i$
For all units combined $D_d^p + D_f^i = FA_f^p + FA_s^i = 2$ (budget deficit)

In the latter case, total debt rises twice as rapidly as cumulative deficits or surpluses. This case, of course, is a very simple one, and the multiplicative factor of 2 is only illustrative.

units would prefer over real assets or the direct security issues of ultimate borrowers. The role of the banks has been, second, to transmit the borrowed funds to spending units with deficits, receiving in exchange direct securities for their own portfolios. Finally, the banks have exchanged direct securities with spending units that wish to adjust their relative holdings of securities in direct and indirect form.

When banks are the only intermediary, surplus spending units may choose to accumulate real wealth, direct securities, or deposits and currency. Deficit spending units may finance themselves by retained earnings, by issues of direct securities to surplus units, or by issues of direct securities to banks. The degree to which debt is absorbed by banks, and, hence, the degree to which financial-asset accumulation is in deposit or currency form expresses the preference of spending units for the asset that is fixed in price (as distinct from value).

Before financial intermediaries other than the monetary system assume importance, monetary theory in the sense of theory about the supplying of and the demand for money relative to the supplying of and demand for direct securities ("bonds") is a perfect balance-sheet counterpart for income theory, saving-investment theory, or surplus-deficit analysis. In so simple a financial system the disposition of surpluses and deficits is accounted for completely by accumulation of direct debt and of indirect debt in money form. Economic theory can appropriately limit its attention to goods, bonds, and money as long as the institutionalization of saving and investment is confined to the monetary system.

In this country, especially since 1900, the innovation and growth of other financial intermediaries have greatly diversified the channels through which loanable funds can flow, the types of financial assets that surplus units may acquire, and the markets on which deficit spending units may sell direct securities. Prior to 1900 the commercial banks shared the field of intermediation with mutual savings banks, savings and loan associations, insurance companies, and a few lesser competitors. To these competitors have been added, since 1900, the Federal Reserve banks, public and private pension funds, governmental insurance and lending agencies, postal savings, credit unions, private investment companies and others. Each of these intermediaries issues its distinctive form of indirect debt—for example, savings deposits, savings and loan shares, pension claims—and thus provides a distinctive package of financial services as a financial asset for spending units to accumulate in substitution for direct debt or money. They compete among themselves, with banks, and with direct finance, for the direct securities that emerge from deficit units. Institutionalization of saving and investment has amounted to differentiation of product in the field of finance.

How nonmonetary financial intermediaries fit into a complete set of social accounts is clear. In the process of economic change and development spending units with surpluses accumulate financial assets, direct and indirect, with the indirect assets taking more variegated form. Spending units with deficits accumulate indebtedness, with the debt outstanding to more diversified bodies of creditors. Aggregate debt rises at a faster pace relative to wealth if deficits and surpluses rise relative to income, if income rises relative to wealth, and if an increasing proportion of direct debt moves into the portfolios of financial intermediaries.

The familiar trichotomy in theory of goods, bonds, and money does scant justice to this complex pattern of real and financial change. By implication financial intermediaries other than the monetary system are netted out of the social accounts, their holdings of direct debt attributed to their creditors.[8] We argue that any domestic debt can be netted out—direct debt and money too—if one pursues far enough the doctrine that "after all we owe the debt to ourselves." We will argue in the next section that elimination from the social accounts or from economic reasoning of any significant body of debt conceals determinants of economic behavior on the part of spending units.

We are deviating from conventional doctrine in regarding the banking system as one among many financial intermediaries, sharing with the others the functions of indirect finance. We take exception to the view that banks stand apart in their ability to create loanable funds out of hand, while other intermediaries in contrast are busy with the modest brokerage function of transmitting loanable funds that are somehow generated elsewhere.

Neither banks nor other intermediaries create loanable funds. That is the prerogative of spending units with surpluses on income and product account. Both banks and other intermediaries have the capacity to create special forms of financial assets that surplus units may accumulate as the reward for restraint on current or capital spending. Banks alone have the capacity to create demand deposits and currency, to be sure, but only savings and loan associations can create savings and loan shares: both "create credit," both transmit loanable funds, both enable spending units to diversify their portfolios.

Banks do have a virtual monopoly of the payments mechanism, and only claims upon monetary intermediaries embody the privilege to use this mechanism. The fact that other intermediaries make use of the payments mechanism, which the banks administer, has sometimes been

[8] Even the monetary accounts are too rarely retained explicitly in the accounts. For an unusual and interesting experiment in keeping the income accounts and monetary accounts together see Henry K. Heuser, "Recent Financial Changes in Western Germany," *Fed. Res. Bull.*, Oct. 1954, XL, 1041-50.

interpreted to mean that other intermediaries have the inferior role of brokerage in loanable funds while the banks have the superior role of creation of loanable funds. Both types of institution, on the contrary, are loanable-fund brokers. Both create credit. Whether it is the banks or others which create credit in any period depends not on the banks' role in administering the payments machinery but instead on the preference of spending units for deposits and currency to hold as against other financial assets to hold.

C. *Financial Trends in the United States.* Table I itemizes some rough measures of change over the past half-century in this country's aggregate debt structure. National financial assets have risen by half again as much as wealth. Financial assets owned by intermediaries, in turn, have risen by half again as much as national financial assets: indirect debt has been a growing proportion of total debt. Self-finance and direct finance have accounted for a diminishing proportion of flows of loanable funds.

TABLE I—ACCUMULATION OF FINANCIAL ASSETS, 1900–1949[a]
(percentages)

	1900	1929	1949
Proportion of:			
1. National financial assets to national wealth	82.1	123.2	124.9
2. Financial assets of financial intermediaries to national financial assets	25.5	28.6	38.5
3. Financial assets of commercial banks to national financial assets	13.9	12.2	14.0
4. Financial assets of commercial banks to financial assets of all other financial intermediaries	119.7	75.0	57.3
5. Financial assets of commercial banks to financial assets of other private financial intermediaries[b]	120.5	83.7	94.7
6. Financial assets of commercial banks to national wealth	11.4	15.1	17.5
7. Financial assets of commercial banks to gross national product	53.9	63.8	60.1
8. Money supply to financial assets of financial intermediaries other than commercial banks and Federal Reserve banks[c]	66.5	31.9	16.8

[a] R. W. Goldsmith, *The Share of Financial Intermediaries in National Wealth and National Assets, 1900–1949*, p. 97. Data from this source have been adjusted in Table I for improved estimates that Goldsmith will publish in subsequent studies.

[b] "Other private financial intermediaries" exclude Federal Reserve banks, government lending institutions, government insurance and pension funds.

[c] The money supply in this case includes adjusted demand deposits and currency outside banks.

The commercial banks' share of all securities has been nearly constant, in the range of 12-14 per cent. But the proportion of their holdings to those of other intermediaries fell by more than half in 1900-1949, from 119.7 per cent to 57.3 per cent. Their relative participation in indirect financing has declined. As comparison between items (3)

and (5) in Table I indicates, a little less than half of their loss in status can be traced to the rise of the Federal Reserve and of government financial institutions, while a little more than half is attributable to gains made by financial intermediaries of a private character. The commercial banks have grown at a faster pace than national wealth and national income, but they have lagged behind the pace of general financial development. To a smaller degree, as item (8) suggests, creation of money by the monetary system as a whole has lagged behind creation of indirect financial claims by other financial intermediaries.[9]

III. *Output Growth, Interest, and Finance*

For nearly two decades analysis of income, interest, and money has conformed to the Keynesian model. This model is not an efficient instrument for studying economic development in either its real or its financial aspects. On the side of goods, the model is inefficient because it does not allow for the effects of investment and of growth in the labor supply on output capacity. Once these effects are admitted, as in the Harrod and Domar growth models, investment appears in a dual role. As an element in effective demand, it is an economic stimulant, but as an increment in capacity its effects may be depressing.

On the side of finance, the Keynesian model is inefficient because it does not allow for the effects of spending and deficits on debt and on financial capacity of spending units to sustain their spending. Deficits, like investment, leave an economic residue. In the case of investment, the residue is output capacity. In the case of deficits, the residue is debt and a change in financial capacity.

A. *The Liquidity-Preference Model.* The Keynesian or liquidity-preference model embraces so short a time period that current expenditures, including investment, cannot lead to an increase of wealth or of direct debt.[10] The model appears to exclude borrowing, so that loanable funds cannot flow and cannot affect the rate of interest. However, in

[9] For an exhaustive listing of financial intermediaries, the reader is referred to various writings of R. W. Goldsmith. These include: *The Share of Financial Intermediaries in National Wealth and National Assets, 1900-1949*, National Bureau of Economic Research, Occas. Paper 42 (New York, 1954); *Financial Structure and Economic Growth in "Advanced" Countries, op. cit.; A Study of Saving in the United States* (Princeton, 1955)

Goldsmith has classified intermediaries as follows: (1) The banking system (Federal Reserve banks, commercial banks, savings banks, the Postal Savings system); (2) Other depository organizations (saving and loan associations, credit unions); (3) Insurance organizations (private life insurance, private pension funds, government insurance and pension funds, property insurance companies); (4) Other financial intermediaries (investment companies, Land Banks, mortgage companies, finance companies, security brokers and dealers, government lending institutions, personal trust departments, commercial paper and discount houses, acceptance dealers, foundations, title guaranty companies).

[10] Short-period, self-liquidating "finance" was an afterthought which Keynes apparently did not regard as a deviation from the initial form of his model. It was a temporary rise in direct debt, shortly to be liquidated.

Keynesian dogma, the rate of interest does depend on *past* flows of loanable funds though it does not depend on current flows. Past flows have left the heritage of a stock of direct debt or bonds. The distribution of past flows between direct channels of finance and one indirect channel, the monetary system, has affected the allocation of bonds between spending units and the monetary system, and as a result, the proportion of bonds to money in the portfolios of spending units.

Though the stock of bonds cannot rise in the Keynesian short period, the historic distribution of bonds can be changed, according to the dictates of monetary policy, by monetary techniques. The function of monetary techniques is, in fact, to transfer bonds between the banking system and spending units and, if fortune smiles upon the authorities, to change in the desired direction the marginal rate of preference by spending units for bonds against money.

To the degree that bonds are held by banks, spending units hold money created by the banks. An ample supply of money implies in the Keynesian model that the taste for liquidity is relatively sated.[11] With bonds in short supply to spending units, the taste for interest is relatively unsated, and the price of bonds in terms of money is high. If bonds are held not by banks but by the public, money and liquidity are in short supply. Then the taste for interest income is relatively sated, bond prices are low in terms of money, and the interest rate is high.

Given factors that affect the intensity of demand for liquidity and money—income, speculative anticipations, and precautionary needs—the price of bonds depends on where bonds are, whether in the portfolios of banks or in the portfolios of spending units. In static equilibrium, the distribution of bonds must yield that rate of interest at which, given the level of income, *ex-ante* surpluses and deficits are equal and spending units are content with the division of their financial assets between bonds and money.

This Keynesian model is inappropriate to financial aspects of growth analysis for two reasons. First, it does not permit direct debt to accumulate and affect financial determinants of spending. Second, it admits only two kinds of financial asset, money and bonds, on the assumption that the stock though not the location of bonds is fixed. The model is not hospitable to the financial intermediaries whose development in recent decades has diversified indirect finance and marked commercial banking as a relatively declining industry. Briefly, the financial aspects of the Keynesian model ignore the long-period ac-

[11] Keynes, it will be remembered, had his doubts about equating money and liquidity if money is defined in some narrow way. See, *General Theory of Employment Interest and Money*, p. 167.

cumulation of securities and the secular institutionalization of saving and investment.

B. *Debt Accumulation and Interest Rates.* The Keynesian model may be adapted, first, by extending the time period to permit loanable funds to flow and debt to accumulate. We may continue to suppose, for the time being, that debt and financial assets consist of bonds and money. The revised model needs to be a dynamic one in which divergent rates of growth in wealth, income, and debt influence the willingness of spending units to incur deficits and debt and to accumulate financial assets.

Suppose, for the moment, a given level of national income and of demand for transactions balances of liquidity.[12] Suppose, also, a given disposition on the part of spending units to incur deficits and to finance them by borrowing. Then, if loanable funds take only the direct route with none flowing through the banking system—if the supply of money is fixed— accumulating bonds accrue to surplus spending units, and deficit units incur an increasing bulk of debt. The effect on both types of spending unit may well be such as to disturb an initial aggregative equilibrium.

The portfolios of surplus spending units deteriorate, as bonds or illiquid assets gain relative to liquidity in money form. This decline in the liquidity index of their portfolios may induce surplus units to express a *diversification demand* for additional money balances that does not depend on the speculative and precautionary considerations of Keynesian short-run liquidity preference. With the supply of money given, the diversification demand may bring about a rise in interest rates that can depress national income below its initial level.

Surplus units, then, may absorb an increasing stock of bonds only at a rising discount. Meanwhile, the propensity of deficit units to spend may decline as debt accumulates over a succession of periods and as debt charges gain on income. A fall in interest rates, or a general easing in credit conditions, may be needed to prevent suppression of spending. A growing disinclination on the part of deficit units to issue debt at given interest rates may accompany the rising diversification demand for money relative to bonds on the part of surplus units.

Because of debt accumulation, equilibrium at the given level of income is threatened. Just as investment may add to output capacity and so jeopardize the level of national income, the issue of debt through the

[12] Our purpose, in assuming national income constant at the first step of the analysis, is to isolate the accumulation of debt as an independent determinant of the demand for money or its substitutes. Debt can and does accumulate even when income is falling as well as when it is constant or rising. So a monetary authority cannot safely adopt the rule that demand for money increases only as income grows—or only as conventional speculative demand rises.

channels of direct finance may have its deflationary impact through the responses of both deficit and surplus units.[13]

To protect the processes of growth from this deflationary impulse, the monetary authority would need to permit an expansion of the money supply. It would recurrently ease the position of banks so that some increasing share of loan funds would flow indirectly, and so that money would be sufficiently plentiful in the total of financial assets to maintain or even reduce the level of interest rates. For the ease of mind of the economy, the monetary authority should announce that it would underwrite expansion of the money supply at the annual rate of x per cent even if national income were to remain constant. If the authority did not act, deficit spending units would be forced into direct finance and ultimately to self-finance on a falling level of national income.

The optimal rate of increase in the money supply, at a given level of income, would vary according to the illiquidity of bonds that the banks would buy. The rate could be relatively low if the banks were, for example, to lend long and leave to the public the more liquid short-term assets. The rate would be high if the public were left with a scant supply of more or less close substitutes for money. The optimal growth in the money stock, at a given level of income, depends then on the accumulation of debt, the effect of indebtedness on deficit spending, the asset preferences of surplus units, the maturity structure of the debt and its other qualities, and the character of the banking system's portfolio.

If income rises, too, along with output capacity and debt, the pressure on interest rates is even more emphatic. The rise in income intensifies the transactions demand for liquid balances. If steady growth in output requires stability in interest rates and other terms of lending, monetary policy must induce expansion in the money supply to satisfy the diversification and transactions demands for money that result from rising debt and rising income. The banking system must be permitted to grow so that the portfolios of surplus units will not be oversupplied with bonds and undersupplied with money.

How fast the money supply must rise, to stabilize terms of lending when income is rising, depends partly on the rate of increase in income. Evidently the money supply must keep in step with demand for money balances. The diversification demand depends on the stock of debt, which falls in proportion to income the more rapidly income gains. While the diversification demand may become smaller in proportion to income, as the pace of growth in income increases, the transaction demand may grow proportionally with income. The sum of these demands,

[13] Joan Robinson, "The Concept of Hoarding," *Econ. Jour.*, June 1938, XLVIII, 235.

then, lags behind income as income gains at a faster pace. It follows that the ratio of increments in the money supply to increments in the income level can be reduced as income gains at a faster pace. The marginal velocity of money may rise, without strain on credit conditions, if income is sufficiently buoyant.[14]

C. *Interest Rates, Money, and Other Financial Assets.* In the standard model the rate of interest depends on the proportional allocation of bonds between spending units and the financial institutions that create credit in the form of money, or "pure" liquidity, for spending units to hold as a substitute for bonds. In so rigid a form, nonbank financial intermediaries are neglected. There have been desultory efforts to correct this rigidity.[15] The definition of money has been widened at times to include time deposits, and the point is sometimes made that still other financial assets have the quality of liquidity only a little diluted. They, too, it is implied, should be added to the liquid things that the public may choose over bonds, and the institutions that issue them should somehow be attached peripherally to the monetary system. Then, presumably, the rate of interest can depend on the distribution of bonds between the public and this expanded "monetary" system.

A more decisive break with liquidity-preference theory seems advisable. Liquidity is not the only characteristic that distinguishes bonds from alternative financial assets. Each financial intermediary offers its own differentiated product for the public to hold. This product is competitive with bonds. It may be more or less liquid than bonds, but it embodies a service, perhaps insurance, that bonds do not. The product is also competitive with money narrowly defined, offering less in liquidity perhaps but offering as well security, interest, insurance, and other services. In view of the increasing variety of financial assets, it does seem appropriate to abandon liquidity as the pivotal factor in

[14] Suppose that spending units issue debt in a proportion of their deficits which, in turn, are b proportion of national income Y. For present purposes, we may assume ab is constant. The issue of direct debt in any period is abY. Spending units may choose, at given interest rates, to hold only e proportion of direct debt issues abY, and may express an incremental diversification demand for money balances of $(1-e)\,abY$. Incremental transaction demand for money balances is $t\,\Delta Y$, so that total incremental demand for money is $(1-e)\,abY + t\,\Delta Y$. Equilibrium requires that the increase in the money supply ΔM should equal demand:

$$(1)\quad \Delta M = (1-e)\,abY + t\,\Delta Y$$

Dividing by ΔY, it follows that:

$$(2)\quad \frac{\Delta M}{\Delta Y} = (1-e)\,ab\,\frac{Y}{\Delta Y} + t$$

Hence, the higher ΔY for a given Y, the lower may be ΔM for a given ΔY and the higher may be marginal velocity or $\Delta Y/\Delta M$

[15] John Lintner, "The Theory of Money and Prices," *The New Economics*, ed. by Seymour E. Harris (New York, 1947), pp. 516-23.

interest theory. The price of bonds, we may say, depends on where the bonds are and on the pattern of preference among spending units for the increasingly rich and variegated menu of financial services attached to financial assets.

A simple exercise in short-period static analysis may suggest the effects of bringing these other financial assets than bonds and money into interest theory. We suppose that the availability of these financial assets does not affect the propensity of spending units to spend on output. The period we consider is Keynesian, and the supply of money and direct bonds is given. In one static position, only bonds and money are available and demanded, and an interest rate is determined. In the comparative position, other financial assets may be supplied and demanded. The difference between interest rates on direct bonds, in these comparative positions, depends in general on the degree to which the other financial assets are substitutes for bonds or substitutes for money.

We assume that supply of the nonmonetary indirect financial assets is infinitely elastic, and that the demand by spending units for these assets brings about a roughly equivalent demand for bonds by nonbank intermediaries. If these other assets are substitutes for the given stock of money in the portfolios of spending units, a demand for them brings nonbank intermediaries to the bond market to compete for bonds with spending units. Then the price of bonds must be higher and the interest rate lower than when banks are the sole intermediaries. The price of bonds rises because the total demand for bonds exceeds the fixed supply at the price which would prevail if only bonds and money were supplied and demanded, or because the demand for money by spending units falls short of the fixed supply at the interest rate that would be appropriate if only bonds and money were available.

If, on the other hand, nonmonetary indirect financial assets are substitutes for bonds in the portfolios of spending units, the price of bonds may be the same in our two static cases. In this situation, the demand for bonds by nonbank financial intermediaries displaces demand by spending units. If nonmonetary indirect financial assets, finally, are substitutes for both bonds and money, their effect must be a fall in the interest rate of smaller magnitude than we expect when only the demand for money is affected.[16]

D. *Suggestions for a Financial Theory of Growth.* A theory of interest and income which allows for accumulation of debt and for the

[16] The analysis in the text may be illustrated by a diagram adapted from Lerner. In the diagram L is the demand for money, and S is the supply of money. A is total financial assets of spending units, increasing as the value of the fixed stock of bonds rises with falling interest rates. The horizontal distance, at any interest rate, between L and A is the

growth of nonmonetary financial intermediaries is a more useful tool than short-period liquidity-preference theory for analysis of economic development. Such analysis of development on the side of finance should, of course, be integrated with analysis of development in real terms.

The investment component of national income, together with growth in the labor supply, raises output capacity. Given the consumption function, investment must rise, from period to period, to generate the

---

demand for bonds. The horizontal distance, at any interest rate, between S and A is the supply of bonds. The equilibrium rate of interest is OR, because at that rate there is equality between supply and demand for both money and bonds.
Assume now a demand by spending units for other financial assets. Assume, too, that they are substitutes for money. The demand for them at OR is NP, so that the demand for money is shifted to L' from L. NP measures also the excess supply of money at interest rate OR and the demand for bonds by nonbank intermediaries. Since at OR there is both an excess supply of money and an excess demand for bonds, the rate of interest must fall to MP'.

Assume, next, that the new financial assets are substitutes for bonds. A rise in demand for them does not affect the demand for money which remains at L. At OR rate of interest, the public's PN' demand for other financial assets than bonds is replaced by new institutional demand for bonds. The rate of interest is not affected.

If the other financial assets are substitutes for both bonds and money, the L curve shifts somewhat to the left, yielding an interest rate between MP' and MP. There are still other possibilities. For example, the financial assets other than bonds and money may be substitutes for money but complements of bonds. Then the interest rate must fall very sharply to accommodate the increase in demand for bonds by both spending units and nonbank intermediaries. If the other financial assets are complements of money but substitutes for bonds, evidently the rate of interest must rise. Both of these cases would appear to be unrealistic.

The analysis of multidimensional asset choice does not fit comfortably into the diagram's conventional geometry of liquidity preference. The NP demand for financial assets other than bonds or money is not solely a demand for liquidity. It is also a demand for security, income, insurance, and other services. Since, over the past half-century, NP has grown relative to an expanding RT, "liquidity preference" has come to be less and less relevant to determination of the rate of interest.

demand that is compatible with expanding capacity to produce. Otherwise some capacity lies idle, and the excess jeopardizes growth. If investment is accelerated by change in income, there is some rate of income growth that equates *ex-ante* saving and investment, or surpluses and deficits, at full-capacity output.

At this warranted rate of growth in income, with deficits and surpluses equal *ex-ante*, planned issues of debt by deficit spending units are equal to planned additions to financial assets by surplus spending units. Still the plans of deficit units and surplus units may be incompatible on financial grounds. At terms of lending which are appropriate to the warranted path of investment, surplus units may be disinclined to buy the entire direct debt issue of deficit units. Apart from changes in the speculative outlook for securities, surplus units should be expected to express a diversification demand for indirect financial assets and, in addition, a transactions demand for money to keep active balances in step with the rising level of income. If the warranted rate of growth in income is to be achieved, there must be some way of satisfying the demand for indirect financial assets that arises out of the rise in income, and the rate of interest that is relevant to it.

At the warranted rate of growth in income, illiquidity accumulates in the form of direct debt and exerts an upward pressure on interest rates that may inhibit income growth. Also, if income grows at its warranted pace, the demand for indirect financial assets, which deficit spending units cannot supply, also grows at some specifiable pace. Any complete growth model must reconcile the accumulating stock of illiquidity with the growing aversion to illiquidity at terms of lending that are suitable to the investment component of warranted income levels. The reconciliation evidently involves growth of financial intermediaries to absorb illiquid direct debt and to issue indirect debt according to the preference patterns of surplus spending units. Even if the warranted rate of growth in income were zero, direct debt would continue to grow and some portion of it would need to find its way into portfolios of intermediaries.

The need for indirect finance to hold interest rates on their optimal trend does not necessarily imply a high rate of growth for banking assets and the money supply in a buoyant economic system. Indeed the banking system may stagnate, without ill effects on the growth rate of income. In the growth process, spending units may choose to diversify their portfolios by adding to their holdings of nonmonetary indirect financial assets. Then, nonbank intermediaries absorb the requisite share of direct debt at the appropriate price. The growth of nonbank intermediaries relative to the banking system may imply

even downward pressure on interest rates at the very time when the growth of income is leaving the money supply far behind.[17]

In long-period analysis, it is a mistake to suppose that the optimal growth of the money supply is some simple function of trends in income or even of income and debt. The necessary growth in the money supply may be high or low, positive or even negative, depending on the growth of income, the share of spending that is externally financed (especially by long-term securities), the growth in demand by spending units for direct relative to indirect financial assets, and on the development of financial intermediaries whose indirect debt issues are competitive with money.

The complexities of a growth model that incorporates the financial as well as the real conditions of growth appear, for the present at least, to defy simple or even systematic formulation. The Keynesian short-period model is certainly inadequate, for the reasons we have mentioned and for others too. For example, its money markets are competitive markets where a host of deficit units meet a host of surplus units under the watchful supervision of the central bank. Rates on these markets may vary sharply in short periods. The rise of indirect finance implies that relatively few and relatively large intermediaries are interposed between ultimate lenders and ultimate borrowers. The result is that capital rationing becomes a more important allocative device, with the rate of interest tending to stabilize about its trend line.

Again, in the Keynesion model, "the" interest rate may fall to a floor that is established by absolute liquidity preference on the part of spending units. One apparent effect of indirect finance, of the institutionalization of saving and investment, is to reduce this irreducible minimum. Nonbank intermediaries may drive bond prices high both because funds must be invested to cover operating expenses and because, while the intermediaries are growing, the continuous net receipts of new funds make asset liquidation unnecessary. Growing intermediaries are "firm hands" that may acquire and hold both bonds

[17] This point may be put more concretely in terms of a modified form of equation (2) in note 14. It is necessary only to take into consideration the fact that part of the diversification demand for indirect financial assets (which in note 14 took the form solely of a demand for money balances) may in fact be satisfied by nonmonetary indirect financial assets. If, as before, the incremental diversification demand for indirect financial assets is $(1-e)abY$, suppose that $m(1-e)abY$ is the share of this incremental diversification demand that is satisfied by currency and deposits Then it appears that the rise in demand for money as income grows is affected by the rate of income growth $(\Delta Y/Y)$, the course of deficit finance (b), the issue of direct debt (a) to finance deficits, the demand for indirect financial assets $(1-e)$, the share of this demand which can be satisfied by nonmonetary indirect financial assets $(1-m)(1-e)$, and the intensity of the transactions demand for money (t).

and equities at prices which would be unreasonably high in a more primitive financial system.

An additional complexity is that development of financial institutions, including nonbank intermediaries, is both a determined and a determining variable in the growth process. The accumulation of assets and the secular rise in incomes stimulate the demand by spending units for financial services in increasing variety. The income elasticity of demand apparently is high not just for liquidity but for financial services in general, and the result in this country is that indirect finance has gained more rapidly than income, wealth, and direct debt. Moreover, any rise in interest rates brought about perhaps by a combination of restrictive monetary policy and accumulating debt creates the opportunity for nonbank intermediaries to offer more expensive attractions to creditors and hence to compete more actively with banks.

A shifting pattern of deficits and surpluses in the growth process may create opportunities for some intermediaries and destroy opportunities for others. All deficit spending units are not equally congenial borrowers for banks and for other intermediaries. All surplus units do not have the same complex of preferences among the financial issues of banks and other intermediaries. This financial incompatibility of spending units and intermediaries may give rise to "matching" problems, in which a shifting distribution of surpluses between spending units favors certain intermediaries that cannot, by law or custom, purchase the concurrent direct issues of deficit spending units. Then there is pressure to change the law or custom, the composition of direct debt, or preferences for financial assets among surplus units. Matching problems that stimulate financial innovation may arise in many other ways, for example from changes in the form of investment or in the geographic location of economic activity. The process of growth conditions, in these and other ways, the relative development of indirect finance in comparison with self-finance and direct finance, and the share of indirect finance that flows through banks and their competitors.[18]

[18] The processes of growth affect and are affected by other financial institutions than intermediaries. The stock market is a case in point. Bullishness on the market may increase the attractions of direct finance, reducing the rate at which intermediaries must grow in order to achieve an optimal trend in security prices. Bearishness may depress direct finance and require more rapid growth by intermediaries. In long periods the volume of dealings on the market, the behavior of its prices, and their importance to income levels are influenced by trends in methods of finance. When self-finance predominates, the market is a subsidiary element of the financial system, and even wide swings in its prices may affect investment negligibly. With development of direct external finance, price behavior on the stock exchanges should exert significantly greater influence on spending. Once indirect external finance has gained stature, financial intermediaries as large purchasers of direct securities may steady the market, reduce the frequency of wide price fluctuations, and moderate the influence of price fluctuations on deficit spending.

E. "MV" *and Financial Theory*. Conventional short-period doctrine about money and interest can be phrased in terms of the velocity of money. Velocity rises as the proportion of transactions balances (with positive turnover) gains relative to speculative balances (with zero turnover). This proportion is raised by an increase in income, given the money supply, or by a decline in the money supply, given the level of income. Since an increase in income or a decline in the money supply increases the interest rate, the interest rate is positively correlated with velocity.

Various exceptions to this relationship are familiar. Velocity may vary, with the interest rate given, if liquidity preference is infinitely elastic. The interest rate may vary, with velocity unchanged, if liquidity preference has zero elasticity. A shift in liquidity preference may disturb the relationship. Again, if both the money supply and income are variable, the relative behavior of velocity and interest rates depends on the elasticity of liquidity preference and marginal efficiency, and on the consumption function. For example, with liquidity preference inelastic, marginal efficiency highly elastic, and with a high marginal propensity to consume, one might expect a fall in interest rates simultaneously with a rise in the marginal velocity of money. The outcome for average velocity would depend, of course, on its initial level prior to the adjustment. The relationship of velocity to interest rates may be changed, too, by shifts in the spending functions.

The relationship between velocity and interest rates is still more attenuated when one allows not only for the complications listed above but also for the diversification demand for money and for the substitutability between money and other indirect financial assets. The diversification demand depends on the level of income, so that marginal and average velocity can vary according to rates of change in income without corresponding changes in interest rates. If other financial assets are available to satisfy the diversification demand, as substitutes for money, the money supply may fall and interest rates simultaneously decline as a reflection of the public's growing preference for these money substitutes. While income and debt are growing, the public may reject money balances in favor of insurance reserves, pension funds, or perhaps savings and loan shares. Because money becomes a smaller share of total financial assets, velocity becomes a less reliable index of interest rates.[19]

[19] In the 1920's nonbank intermediaries gained on banks at an especially rapid rate. The ratio of their assets to assets of banks rose from .77 in 1922 to 1.14 in 1929. In the same period income velocity of money with money narrowly defined, rose from 3.4 to 3.9 while long-term bond rates fell from 4.71 per cent in 1922 to 4.05 per cent in 1928 and 4.42 in 1929. Various reasons for the opposing movements in velocity and bond rate may be alleged, but one of them must have been the unprecedented growth of nonbank intermediaries.

As money becomes a smaller proportion of financial assets and as the demand for it comes to be related in a more complex fashion to interest rates and income, the "money approach" to analysis of interest rates and income loses precision. To make use of MV, one necessarily puts a more and more severe strain on the velocity component, or on the money component by including every financial asset. The strain may be too much to bear since a rise in V, with the narrow definition of money, may mean either that all credit expansion including that of banks is restricted, so that interest rates are rising, or that the flow of loanable funds is bypassing banks at falling rates of interest. If a rise in V is compatible both with credit ease and with credit tightness, one is tempted to conclude that time and financial evolution are outmoding V as an analytical tool. The allied concepts of hoarding and dishoarding necessarily fare no better.

If the MV approach to accounting for security prices and flows of income is ambiguous, so too is the monetary approach to explaining the level of prices for commodities. Prices of goods may rise because loanable funds are accessible too easily and cheaply through the intermediation of the monetary system. They may also rise because other indirect finance is too ample, given the flexibility of supply in real output. Prices may fall because deficits are depressed not only by "tight money" but by "tight savings deposits" or "tight insurance." As financial evolution proceeds, one salvages conventional quantity theory by so extending the concepts of M and V that they bear little resemblance to "means of payment" and "turnover of means of payment."

IV. *Financial Controls in a Growth Context*

Principles and techniques for regulating flows of loanable funds that are optimal in terms of short-period models, with money as the only indirect financial asset, may not be optimal in a growth context, with diversity of indirect financial assets. This is not the occasion to explore carefully how growth analysis may affect one's perspective on financial controls, but we do wish to point out a few illustrative leads.

A. *Monetary Control.* In the conventional short-period model, monetary controls shift direct debt between the central bank, the commercial banks, and the public. The effect is to change the money supply and the valuation of direct debt in terms of money to a degree that depends on speculative, precautionary, and transactions demands for money balances. This adjustment in the interest rate affects, perhaps, expenditures of spending units, their deficits, and so the flow of loanable funds.

There have been many proposals regarding the policy that should guide monetary controls in the long run; for example, that the money

supply should be induced to grow at a constant rate, or at the same rate as income, or at a rate higher than income to accommodate, say, the rising demand for liquidity that might result from gains in income or wealth per capita. One recalls, of course, the policy prescription that money should accummulate fast enough to keep the interest rate at its presumed irreducible minimum. None of these prescriptions seems to account adequately for effects on terms of lending of changes in growth rates of income and debt, in the structure of debt, in the variety of financial assets, and in relative demands for competitive varieties of financial assets.

Suppose, for the moment, that banks are the only intermediaries. We have seen previously that the behavior of national income cannot properly be the sole criterion of monetary policy. Growth in stocks of debt and output capacity may require growth in the stock of money even with the flow of income constant. But the monetary expansion associated with any growth curve of debt may be reduced if the direct debt itself can satisfy the diversification demand for financial assets. So short-term public debt may displace money, and debt management may displace monetary controls. In general, public-debt management and monetary controls should have identical goals, of satisfying the complex demand of spending units for financial assets at given terms of exchange between direct debt and money. There should be no opportunity whatever for them to work at cross-purposes.

At rising income levels there can be no simple formula of monetary expansion, even when money is the only indirect financial asset. To satisfy the transactions demand for balances, money may need to grow as fast as or faster than income. To satisfy diversification demand, at given interest rates, it may lag behind income. To offset the effects of growing output capacity and growing debt on propensities to spend, it may need to run ahead of income. How speculative and precautionary demands for balances vary as income rises is not apparent. For any rate of gain in income, the optimal growth of money cannot be determined independently of the specific growth context.

Growth of the money supply implies growth of the monetary system, especially of the central bank and the commercial banks. If the latter's reserve requirements are stable, they and the central bank must grow at about equal rates, each continuously absorbing direct debt of deficit spending units. With varying reserve requirements, commercial banks and central bank may grow at different rates. If reserve requirements rise for member institutions, the central bank acquires direct debt and supplies new money balances. If reserve requirements fall, the commercial banks do the job of indirect finance.

In view of its portfolio limitations, the central bank can grow most

readily when deficits are in the government sector. Relative growth of the central bank when government debt is a fixed stock has the disadvantage of withdrawing from the markets government securities that may be more or less close substitutes for money. In this case, to maintain interest rates, the money supply may need to grow faster if it is provided by the central bank than if it is supplied through purchases of private securities by commercial banks.

If accumulating direct debt is private debt and if the central bank is subject to customary restraints on the kinds of assets it may hold, monetary growth apparently should be concentrated in commercial banks, and their reserve requirements must take the downward trend. This prospect is disturbing on at least two counts. First, for reasons well known in banking theory, low reserve requirements for commercial banks increase short-period instability in the money supply. Second, the commercial banks can assume only at some risk the responsibility for supplying a rising share of indirect finance. As principal administrators of the payments mechanism, they must be solvent beyond doubt. As financial intermediaries, on the other hand, the commercial banks must underwrite the growth process with venture finance, buying securities from spending units that are taking the risk of innovation and expansion. In one role, the banks must minimize risk; in the other role, risktaking is necessary and proper.

Unless, then, there are government deficits in the growth process, the monetary system is not the ideal vehicle for financial growth. The direct securities that accumulate with real growth in the private sector do not tend to match the portfolio requirements of the central bank or of an indubitably solvent commercial banking system. This handicap can be counterbalanced if the central bank portfolio is liberalized or, say, if there are government guarantees of bank deposits and bank assets. It can also be aggravated by unimaginative bank management or such restrictive banking regulation as the ban on branch banking which keeps the lending capacity of individual banks from growing with the borrowing requirements of individual deficit spending units. The fact is, in this country, that the banking system has not been able simultaneously to keep solvent, to absorb even a constant share of the expanding supply of direct securities, and to keep pace with the expanding demand for indirect financial assets.

B. *Financial Control.* Inadequacy of the monetary system has at least two effects. It provides an incentive to self-finance, especially for large business firms. Second, it creates opportunities for competitive development of nonbank financial intermediaries. When monetary expansion is restrained, real growth supplies the direct securities at at-

tractive prices as well as the demand for indirect financial assets that other intermediaries can exploit.

These nonmonetary intermediaries have not been acknowledged generally in this country as competitors with banks, and as substitutes for them, in easing terms of external finance and hence of deficit spending. Regulatory techniques have not been evolved in any systematic way to cope with them as instruments of indirect finance. Their equivalent of the Federal Reserve Act is still to come.

The lag of regulatory techniques behind the institutional development of intermediaries can be overcome when it is appreciated that "financial control" should supplant "monetary control." Monetary control limits the supply of one financial asset, money. With a sophisticated financial structure providing financial assets, other than money and bonds, in increasing proportion to both, control over money alone is a decreasingly efficient means of regulating flows of loanable funds and spending on goods and services. Financial control, as the successor to monetary control, would regulate creation of financial assets in all forms that are competitive with direct securities in spending units' portfolios. "Tight finance" and "cheap finance" are the sequels of "tight money" and "cheap money."

A monetary authority which is tempted to stay within the bounds of its traditional controls because they are quantitative, general, and impartial, may find itself more and more out of touch with credit developments in critical growth areas where lending by nonbank institutions is predominant. Traditional controls are more appropriate to competitive loanable-funds markets than to markets that are dominated by a few large institutional lenders such as insurance companies. On imperfectly competitive markets, where a few nonbank institutional lenders are important market forces, capital rationing may become the critical medium for enforcing financial control.

Nonbank institutional lenders give rise to special problems in financial control because they are imperfectly competitive and also because they are specialized. Since they do buy a rather narrowly limited variety of assets and issue specialized varieties of indirect financial claims, there can be a credit impasse that is not characteristic of open and competitive markets for loanable funds. Intermediaries whose debt may be in demand by spending units may be inhibited by law or self-restraint from lending to sectors where demand for capital formation is most active. Traditional monetary controls do not solve this issue of debt incompatibility.

There are solutions. One is to relax legal restraints, say by permitting insurance companies to invest in mortgages and common

stocks, so that intermediaries become less specialized. The intermediaries themselves may venture into new varieties of asset and debt. Secondary intermediaries such as personal finance companies, may arise to assume risks that primary intermediaries avoid. Government institutions may hold securities not wanted elsewhere, may guarantee such securities, or discount them. Solutions for this problem of matching borrower and lender have been found. But they have been found with some delay, and it is not always apparent that they are the optimal solutions.

Central bank operations in long-term public debt may reverberate further through the financial system than operations in short-term debt. According to the doctrine of credit availability, such important intermediaries as insurance companies and savings banks are sensitive to change in bond prices or to uncertainty about bond prices. The liquidity of their portfolios is reduced by a rise in rates on Treasury bonds. To restore liquidity, intermediaries tend to buy still more government securities, possibly of shorter maturity. They tend also to contract direct lending on mortgages or industrial loans. The contraction of lending may mean a rise in interest charges to private borrowers, but its immediate and perhaps most powerful implement is credit rationing.

This availability doctrine acknowledges the parallelism between banks and other intermediaries. It imposes on the central bank responsibility for supervision over indirect finance generally rather than over indirect finance through banks alone. We cannot be sure that it is based on a sound estimate of intermediaries' portfolio practices, but we do regard it as a provocative step in the transition to theorizing about financial control as distinct from monetary control.[20]

Scott, Jr., *Monetary Policy, the Theory of Assets, and the Availability of Credit*, *passim* (doctoral dissertation, Harvard University, 1953); Robert V. Rosa, "Interest Rates and the Central Bank," *Money, Trade, and Economic Growth, Essays in Honor of John Henry Williams* (New York, 1951), pp. 270-95.

THE FACTOR PROPORTIONS PROBLEM IN UNDERDEVELOPED AREAS

By R. S. Eckaus*

The concepts "structural disequilibrium," "overpopulation," "technological unemployment" and "underemployment" appear frequently in the literature on underdeveloped areas and there is considerable discussion of the comparative desirability for use in such areas of relatively labor-intensive or capital-intensive techniques. This paper is intended to help clarify some of the underlying issues and to begin to provide a theoretical basis for their analysis.

Many of the underdeveloped areas of the world have large agrarian populations in which there is either persistent open unemployment or in which the marginal productivity of the working force is so low that it is commonly believed that withdrawal of a sizable fraction would not significantly affect output. This seems to be the case to varying degrees for much of Asia and the Middle East. Other countries, such as Italy, show persistent urban as well as rural unemployment or underemployment. It is a common feature of the unemployment in these countries that it fails to respond to fiscal policy measures designed to increase employment by stimulating effective demand. Use of conventional income-generating techniques appears in fact to create inflationary pressures and balance-of-payments difficulties long before full employment is approached.

This interpretation of the condition of many underdeveloped areas has led to the formulation of a number of alternative explanatory hypotheses which are presented in Section I. One of these hypotheses appears, at this stage of investigation, to be particularly fruitful in casting light on some of the outstanding characteristics of underdeveloped areas and is elaborated in Section II. Two approaches to the problems of empirical testing of the hypotheses are outlined in Section III.

* The author is assistant professor of economics, on leave of absence from Brandeis University, and presently research associate at the Center for International Studies, Massachusetts Institute of Technology He wishes to express his gratitude to the Center for International Studies, under whose auspices he did the work upon which this paper is based, to the seminar group of the Center for criticism and encouragement and especially to F. M. Bator and P. N. Rosenstein-Rodan. He is also indebted to P. A. Samuelson and R. Solow for their interest.

The hypotheses presented below suggest that the unemployment difficulties of underdeveloped areas are not basically due to lack of effective demand but stem from "market imperfections," limited opportunities for technical substitution of factors and inappropriate factor endowments.[1] The techniques of analysis of factor market imperfections are well known.[2] The implications of limited technical substitutability of factors were first analyzed by Abraham Wald[3] and more recently by the linear programming techniques.[4] Further development of the theoretical analysis in this paper consists mainly of an elaboration of geometrical techniques, which are used to apply the theory specifically to the problems of underdeveloped areas.

I. *The Factor Proportions Hypotheses*

The analysis which follows has grown out of the suggestion by C. P. Kindleberger that underdeveloped areas such as Italy are characterized by "structural disequilibrium at the factor level." This concept, formulated by Kindleberger and E. Despres, is identified as follows:

> Disequilibrium at the factor level may arise either because a single factor receives different returns in different uses or because the price relationships among factors are out of line with factor availabilities.[5]

This suggestion has been the starting point for two types of explanation of unemployment or underemployment in underdeveloped areas. The first type assumes that available technology would permit full use of the working force at some set of relative prices and finds the source of unemployment in various types of "imperfections" in the price system. The second type suggests that there are limitations in the existing technology or the structure of demand which lead to a redundancy of labor in densely populated, underdeveloped areas. The two types of hypotheses are combined in Section II to obtain a more general analysis.

[1] The hypotheses and analysis have come to be known at the Center for International Studies, M.I.T., as the "factor proportions" problem.

A. *The Market Imperfections Hypotheses*

In the accompanying figure the vertical axis represents the rate of real wages and the horizontal axis the amount of labor. The curves *DD'* and *SS'* represent the aggregate supply and demand relations for a typical industry if factor markets are competitive. Under competitive conditions the wage rate would settle at *E*.[6]

Suppose, however, that trade union pressures, immobility of labor, government social legislation or other factor-market imperfections maintain the wage rate at *W* rather than allowing it to fall to *E*. The effective labor supply curve would be *WS'*. At the higher wage rate the demand for labor would not absorb all the labor available and it could be said, as Kindleberger does, that, *ceteribus paribus*, the wage rate does not represent factor endowments.
FIGURE 1

To isolate the influence of various types of imperfections let us now consider a case in which factor mobility, or lack of it, is not important and continue to confine the analysis to a closed economy. If the system had become adjusted to a particular complex of rigidities there would be no need for factor mobility in the absence of changes in techniques or tastes.[7]

[6] Fixed supply and demand curves such as those in Figure 1, suppose, of course, constant resources, technology and consumer tastes.

[7] "If effective demand always moved up and down in the same well-worn channels, a supply of each type of labor would always be ready waiting to meet demand for it, when effective demand expanded, and the question of mobility would not arise." Joan Robinson, *op. cit.*, p. 30.

The comparative use of the factors of production, depending as it does on the factor-price ratios and technology, would, however, reflect the "true availability" of labor only if wages were kept at E in Figure 1. If wages are kept at W there is an "artificially" high ratio of the price of labor to the price of capital. Since we are explicitly assuming that factor substitution is, in fact, possible, a structure of production may result with a higher capital-labor ratio than otherwise. If the diagram were representative of large parts of an economy, as output increased full employment of the given labor force would require the use of more capital than if the structure of production were adjusted to a lower labor-capital price ratio, unless the substitution effects were offset by increasing returns to scale. In a country in which capital was scarce and unemployment of considerable magnitude, the attempt to achieve full employment by use of relatively capital-intensive investment would be more likely to lead to inflation and balance-of-payments difficulties, short of full employment, than if more labor-intensive techniques were used.

The development of social policy in economically underdeveloped areas frequently proceeds more rapidly than economic growth. Imitation of the techniques of more advanced countries is not confined to technology. Elaborate social security legislation and aggressive government-encouraged union movements are often found in densely populated, low per capita income countries which are just on the threshold of economic advancement. There is little or no scope for such devices for raising wages except in the relatively more advanced and well-organized sectors. Therefore, new industrial projects may face the prospect of wage rates quite different from those prevailing in the handicraft and agrarian sectors and thus may be compelled to use different factor proportions. These considerations suggest that the foregoing analysis may be quite relevant for underdeveloped areas.

The next step in the analysis is to abandon the assumptions of constant technology and consumer tastes and to investigate the effects of changes in the composition of demand for goods and factors due to such influences as changes in methods of production or in the directions or levels of demand as a result of changes in tastes or foreign competition. In this second case, as the level of aggregate effective demand rises, goods will be demanded in different proportions than formerly and the location and magnitudes of the demand for factors of production will shift. If labor is not mobile, or if it takes considerable wage increases to shift it, then factor disequilibrium such as depicted in Figure 1 for the preceding case of constant tastes and technology would develop in certain industries. An increase in the level of effective demand would push other industries to the limits of capacity relatively quickly in

this second case. Money wages and prices would begin to rise, not uniformly but in the "bottleneck" sectors, prior to the achievement of general full employment. New investment in these sections would tend to increase still further the substitution of capital for labor while offsetting tendencies in the relatively stagnant sectors would work slowly, if at all. The balance of payments under the pressure of growing domestic inflationary pressures and increased demand for capital imports would tend also to develop deficits at an earlier stage in the expansion of national income. This could all be superimposed upon and could aggravate the "factor disequilibrium" previously discussed. It would be distinguishable, however, as there would be evidence of excess capacity and stranded capital-goods resources indicating an original misallocation or a structural shift.

There is at least superficial evidence to suggest that the factors stressed in this hypothesis may be operative in some underdeveloped countries. For example, although Italy has a persistent unemployment of about 2 million in a population of around 47 million, there are also some sectors of the Italian economy, such as shipbuilding, in which there is persistent unused physical capital plant and equipment. Moreover, we would expect that in underdeveloped areas the working force would be even more bound by tradition, reluctance to change location and barriers to social as well as physical movement than is the case in more advanced, industralized countries; this would also contribute to the problems created by structural change.

Closely related to this second hypothesis is an explanation which locates the source of factor disequilibrium in barriers to the entry of new firms into profitable industries whose expansion is limited by various types of monopolistic restrictions. This and the other types of "imperfections" could aggravate the "factor disequilibrium."

One further related hypothesis remains to be considered here.[8] Suppose that, whatever the actual characteristics of the production function and degree of technical substitutability of factors, businessmen believe that they face a production function with constant coefficients, *i.e.*, no factor substitution is possible. Indian businessmen, for example, may believe that the "American way" of producing is the best and only way and that this always involves high ratios of capital to labor. Plant engineers accustomed to emulating "Western" technology may not be sensitive to the range of choice actually available in manufacturing processes and may impose unnecessary technical constraints on managers in underdeveloped countries. Thus in Figure 2, although the solid lines. x_1, x_2 . . . may represent the real contours of

[8] I am indebted to F. M Bator for the suggestion of this case.

the production function, businessmen may regard the dashed lines x_1', x_2' . . . as the ones along which they must move.

In this case the expansion path P would be independent of the factor-price ratios, and, therefore, of the supply curve of labor such as indicated in Figure 1. Expansion of effective demand would tend to run into the limits imposed by capital capacity prior to the achievement of full employment with consequent inflationary tendencies and balance-of-payments difficulties. This could take place even if Figure 2 were not characteristic of all sectors of industry.
FIGURE 2

B. *The Technological Restraints Hypothesis*

It is fairly common for observers to report finding modern, capital-intensive equipment and techniques used in underdeveloped areas where relative factor prices would suggest the use of more labor-intensive techniques. I should now like to suggest that the use of the "modern" techniques is not necessarily irrational emulation but the result of real limitations in the technological choices available, and that this, in turn, is a major source of labor employment problems in underdeveloped areas. At this point the exposition will be oversimplified to indicate in stark outline the nature of the argument. In the next section the hypothesis will be combined with some of the market imperfections hypotheses in an attempt to describe some of the major characteristics of underdeveloped and overpopulated areas by the use of a relatively simple theoretical framework.

The basic assumptions of the following analysis are: (1) in large sectors of an economy there are only a few alternative processes which can be utilized; (2) these processes are relatively capital-intensive.[9] There have been frequent comments which describe certain features of underdeveloped and overpopulated areas as essentially the result of limited variability in the coefficients of production. An example of this kind of comment is the frequently observed "underemployment" in agriculture, where this is taken to mean that, with agricultural techniques remaining unchanged, withdrawal of farm labor would not reduce output.

The Case of One Good, Two Factors and One Process. In the first, most simple case to be considered, suppose that only one good is produced in the economy, national product, which requires two factors,
FIGURE 3

capital and labor.[10] Assume also that only one process can be used to produce national product, *i.e.*, that the factors must be used in fixed proportions. This situation is represented in Figure 3, where the heavy

[9] A production "process" is a way of combining different factors of production whose *proportions* are determined by technology, although the *scale* of production and thus the absolute quantities of the factors used may be freely variable.

[10] Confining the analysis to only two factors is not essential but highly convenient for geometrical demonstrations.

black line represents national output, x_1 of 1 unit; the lighter lines represent higher outputs. Quite irrespective of relative factor prices, points *a*, *b*, *c*, etc., represent the combinations of factors which will be used to produce output and the slope of the line joining these points is equal to the constant, capital-labor ratio.

Only when the factors of production are actually available in proportions equal to the fixed capital-labor ratio is there the possibility that both can simultaneously be fully utilized. If the actual factor endowment is off the line *oabc*, for example, at point *E*, there must inevitably be some unemployment of labor which is not amenable to any fiscal or monetary policy for its alleviation. Labor is a redundant factor and only by increasing capital stock in the amount indicated by the length of the dashed line can the unemployment be eliminated.[11] Conventional compensatory fiscal policy would, in this case, only result in inflationary pressures. The persistent open and "disguised" unemployment in underdeveloped countries may be at least partially of this kind.

Two or More Processes. Suppose now that a second and a third relatively more labor-intensive process is developed for the production of the same good, national output, so that three processes are now available. This is represented in Figure 4 by the existence of two more right-angled constant-product lines for a unit of output and two additional expansion paths, *ocd* and *oef*.

In addition to the alternative combinations of factors which may be used to produce a unit of output represented by points *a* and *c* and *e*, the lines *ac* and *ce* also represent combinations of factors which will yield a unit of output. It is possible to be between *a* and *c* on line *ac*, for example, by using the first process and the second process in different combinations. If the resources are taken away from the first process, output would fall. But if these resources are then used in the second process, output would rise. It can be shown rigorously[12] and may be appreciated intuitively that there is some withdrawal of factors from process 1 and subsequent use in process 2 which will restore output to the unit level. Correspondingly the line *bd* represents combinations of process 1 and process 2 and of the two factors capital and labor which are optimal for the production of the x_2 level of output.[13]

[11] I recognize that it is stretching a definition considerably to call redundant factors "unemployed." However, since it is specifically the hypothesis of this paper that the labor called "unemployed" or "underemployed" in underdeveloped areas is redundant, I shall, with this warning, use the terms interchangeably.

[12] *Cf.* Dorfman, *op. cit.*, pp. 39-41.

[13] It can be seen by drawing a line from *a* to *e* that, for any output, any combination involving processes 1 and 3 would require more of at least one factor than a combination of processes 2 and 3.

In this second case where several processes are available the proportions in which the two factors can be used are not confined to either the expansion path of the first process or the expansion path of the second process, or both, but may be any place within the area bounded by *oab* and *oef*. Thus the factor endowment E_1, while inevitably implying some unemployment of labor when only the first process was available, can now be fully utilized by using the first process on a smaller scale and switching some of the capital to the second process. If, however, the factor endowment should be outside the area bounded by the
FIGURE 4

two expansion paths, at E_2 or E_3, for example, structural unemployment of capital capacity or of labor would ensue in exactly the same manner as in the preceding case of one process, regardless of factor-price ratios or fiscal policy.

If more than two processes are available to the economy, full employment of all factors will be *possible* at a nonzero wage so long as the proportions in which factors are endowed fall on or within the limits set by the processes with the most extreme factor-use ratios. This suggests an observation which is, by now, almost trite: reduction of underemployment in overpopulated areas requires the addition of scarce factors. This may, however, be accomplished in a variety of ways, such as the use of dry farming methods and drought- and heat-resistant hybrids which increase the land available for farming.

In the case in which just one process is available, changes in relative factor prices can not affect the proportions in which factors are used. This is not true when there are two or more processes available. In this case factor proportions employed will, in competitive markets, vary with factor prices and the achievement of full employment, if technologically possible with the given factor endowment, will depend on factor prices. In Figure 4, r_1, r_2 and r_3 are constant-expenditure lines illustrating three possible sets of factor prices. The line r_2 has the special feature that its slope is equal to that of the constant-product curve between points a and c.[14]

If the price ratio of factors were of the r_1 or r_3 types only one process and one ratio of factors would be used. To employ completely each of the factors in an endowment like E_1, the very special factor-price ratio r_2 would be necessary. A factor-price ratio slightly different from r_2 would be sufficient to move factor use ratios away from E_1 to one of the isoquant vertices. Moreover, having reached a vertex of an isoquant it would be possible for large changes in relative factor prices to occur without leading to factor substitution.

Two Goods and Two Factors. An interesting question is whether the restriction of the analysis to only a single good is responsible for the character of the conclusion. By use of an Edgeworth-Bowley type box diagram we can continue to have the advantage of graphic techniques without loss of simplicity and extend the analysis to the case of two goods.

Let us now assume that we have two goods x_1 and x_2, each of which can be produced by two, fixed-proportions processes, and that constant returns to scale prevail;[15] only two factors, capital, K, and labor, L, are used. Figure 5a shows a few of the infinity of equal-product lines which could be drawn for different outputs of the two goods. The solid lines refer to product 1, the dashed lines to product 2. In Figure 5b, these isoquants are used to construct a box diagram. The dimensions of each side of the box represent the total amount of factors available. Any point within the box simultaneously represents four quantities: the amount of capital and the amount of labor used in producing x_1 which is determined by measurement from the lower left-hand corner, and the amount of capital and the amount of labor used in the x_2 industry, measured from upper righthand corner.

Figure 5b provides the basis for the derivation of the "efficiency

[14] Constant expenditure lines r_4 and r_5 could be drawn analogously to r_2 and r_1, with a slope equal to that of ce, and less than that of ce, respectively.

[15] The assumption of constant returns to scale is, of course, maintained not because it is considered the best description of reality but for its analytical convenience. Some comments on the effects on the analysis of dropping this assumption are made below, p. 556.
FIGURE 5A
FIGURE 5B
FIGURE 5C

locus" for the two goods x_1 and x_2 If production takes place at any point off this locus, it is possible by recombination of factors to produce more of one good without diminishing the output of the other. If along the efficiency locus corresponding amounts of the two goods are read off and plotted on a chart as in Figure 5c, the transformation or production-possibility curve between x_1 and x_2 is obtained.

To locate a point on the efficiency locus we must specify a particular amount of x_1 to be produced and find the maximum of x_2 which can simultaneously be produced. Graphically, we must move along the specified x_1 isoquant crossing x_2 equal-product lines until we reach the highest x_2 isoquant obtainable. The optimum positions achieved will thus be located at tangencies of the x_1 and x_2 equal-product lines where the lines just touch without crossing. Since, in the present case, each equal-product line is made up of segments of straight lines, the optimal

positions will be corner tangencies. By repetition of this maximizing process for a series of points the entire efficiency locus can be determined.

Since in the present case the efficiency locus for the two goods is a rather complicated succession of line segments we shall trace it out carefully. Starting at O_1, zero output of x_1, the maximum output of x_2 obtainable is indicated at point A and could be computed by dividing O_2A by the scale factor applicable to process x_2'. If output of x_1 is now increased relative to x_2, it will be most efficient, at first, to use process x_1' and for x_2 to be produced with process x_2'; production of x_1 would then move along the expansion path O_1B and x_2 should decrease along the expansion path x_2' to point B. In this first stage capital is a redundant factor and labor is relatively scarce. The economic system adjusts to this condition by directing the use of the most capital-intensive processes to be used for the production of both goods.

As production of x_1 is expanded beyond point B it would be best now to use both process x_1' and process x_1'' in combinations indicated by the intersection of O_2A with the constant-product lines for commodity x_1 as long as these intersections lie between the expansion paths of x_1' and x_1''; production of x_2 should continue to be by means of process x_2' alone, however. This second stage is indicated by the points on the segment BC which belong to both the combination of x_1' and x_1'' and process x_2'. By tracing along an x_1 isoquant between B and C it can be seen that shifting to the expansion path O_2A makes possible a larger production of x_2 for the particular output of x_1 than if we had remained on the path O_1B. As production of x_1 is expanded in this stage and production of x_2 is decreased, capital becomes more scarce relative to labor due to the relatively high labor-capital ratio of the resources released by the decrease in production of x_2.

In the third stage, as output of x_1 is farther increased, it is most efficient to use only process x_1''. But now for any given output of x_1, the maximum amount of x_2 can be obtained by use of the more labor-intensive process x_2'' in combination with process x_2'. The third stage on the efficiency locus is indicated by line CD.

Finally, still further expansion of production x_1 continues to be best done along the expansion path of process x_1'' until, at point E, x_1 is being produced to the complete exclusion of x_2. In this fourth and final stage the output of x_2 should be produced only by process x_2''.

Only in the fourth stage and the first stage of the efficiency locus would optimum allocation imply some unemployment of one of the factors. In the first stage the unemployment of capital for different outputs of x_1 and x_2 is indicated by the vertical distance between lines AB and O_1B. In the final stage the unemployment of labor is measured by the horizontal distance between lines DE and DO_2.

Actually the occurrence and qualitative significance of any of the stages depends on both technology and factor endowments. If process x_1'' were relatively more labor-intensive than is shown, its expansion path would pivot to the right and stage 2 in Figure 5b would be prolonged. As common sense would suggest, development of a sufficiently labor-intensive process for x_1 could cause stages three and four to disappear entirely and with them the possibility that there could be an "optimal" configuration which involved unemployment of labor. A similar effect would result from a decrease in the amount of labor endowment. This could be depicted by squeezing together the left- and right-hand sides of the box in Figure 5b. Increasing the labor supply would mean stretching the box horizontally. This would not only increase the range of outputs associated with stage 4 but also, if pushed far enough, first eliminate stage 1, the capital unemployment stage and then stage 2.

The points *ABCDE* on the technical transformation curve in Figure 5c correspond to the similarly lettered points on the efficiency locus in Figure 5b.[16] At first when only a little x_1 is produced and, relatively, a lot of x_2, we should move along the segment *AB* using process x_1' and x_2'. Unemployment of capital associated with this segment on Figure 5b will be reduced as we approach *B*. Relative labor scarcity is limiting along this segment and the slope of the line segment *AB* will depend on the ratio of the labor inputs of output of x_2 to x_1. The relative labor intensity of process x_2' compared to process x_1' as drawn on Figure 5a accounts for the steepness of the segment.

The line segment *ED* on Figure 5c has an exactly analogous justification to that for the segment *AB*. Labor unemployment will be reduced as *D* is approached from point *E*. Capital is the only scarce factor and the relative capital intensity of process x_1'' as compared to process x_2'' accounts for the flatness of *ED*.

Point *C* is located conveniently relative to points *B* and *D*. More of x_1 is produced at *C* than at *B*, though not so much more as produced at point *D*. Likewise less x_2 is produced at *C* than at *B* though not as much less at *D*. The segments *BC* and *CD* will be straight lines as can be verified by noting in Figure 5b that, due to the assumption of constant returns to scale in all processes, there must be a constant ratio between changes in output of x_2 along the line O_2A between *C* and *B*, for example, and changes in output of x_1.

It was pointed out with regard to the efficiency locus in Figure 5b that changes in factor endowment and technology could shorten, extend

[16] In the constant-returns-to-scale case, only relative factor endowments are important in determining the *shape* of the transformation curve. If the absolute factor endowments were changed while relative factor endowments remain constant, it would amount to sliding the northeast and southwest vertices of the box on the connecting diagonal.

or even completely eliminate various stages of the efficiency locus. This applies also to the separate segments of the technical transformation curve. The technical transformation curve of Figure 5c illustrates all the possible stages which could be produced by this simple case, from unemployment of capital to unemployment of labor. It should not be presumed that this range of possibilities will actually exist in a particular system at any one time. Rather, it is the hypothesis of this paper that technology and factor endowments in underdeveloped areas are such that a segment like *DE*, in which labor is redundant, is important in their transformation curves.

To demonstrate the importance of demand conditions for employment when the conditions assumed in the present hypothesis exist, we shall draw a transformation curve in Figure 6 consisting only of stage
FIGURE 6

CD, along which there is full employment of both capital and labor, and the labor-redundant stage *DE*. This can be envisaged as the result of a high rate of population growth which has stretched the labor axis very far. We can now see that actual achievement of full employment depends on the relative demands for the two goods. Market baskets whose composition falls along *CD* will allow full employment; along *DE* labor will be redundant. A geometrical demonstration which is suggestive, though lacking in rigor can be given. Suppose that the lines i_1 and i_2 represent two different possibilities for the community's indifference curve for the two goods. Only in the case in which the in-

difference curve is tangent along *CD* will optimal output imply full employment. The community must face a conflict in goals between full employment and maximum value of output if i_2 is in fact its indifference curve.[17] Extending the analysis to include many goods would widen the range within which factor endowments could vary without unemployment of one or more factors resulting. There would, however, still be no guarantee that the composition of goods demanded would always hit on a full-employment point.

It may also be observed that if it is possible to buy and sell in foreign trade at price ratios between the slopes of *CD* and *DE,* full employment would again be possible though not necessary. To determine whether or not it would result, it would be necessary to know the reciprocal demands for exports and imports.

It would be possible to elaborate this model now by investigating the implications for the analysis of market imperfections such as were considered in the previous section. This extension will be postponed to the following section, however, and applied to a model of underdeveloped areas designed to be somewhat more realistic. As it stands the present analysis gives us, I believe, important insight into the problems of underdeveloped areas. It presents a hypothesis which helps account for the inflationary tendencies of underdeveloped areas under the impact of programs designed to raise effective demand, and for the stubbornness of unemployment in such areas.

The analysis of this section also provides a more precise definition for the "technological unemployment" mentioned in *Measures for the Economic Development of Underdeveloped Countries.*[18] Technological unemployment may be a real problem for underdeveloped areas if it is defined, as in this section, as redundant labor arising from resource and technological restraints and the structure of demand.

II. *A Model of Underdeveloped and Overpopulated Areas*[19]

Though the analysis of the previous section is suggestive, it is hard to believe that all of the unemployment and underemployment in underdeveloped areas represents literally uselss labor. Moreover, the assumption of only a few alternative processes and a quite limited range for

[17] A major qualification to this analysis, still on the static level, is the possibility that the shape and position of the community indifference curves might not be independent of the particular processes or combinations of processes which are used To handle this difficulty it would be necessary to determine the shifts in income distribution which result from changes in factor prices and to explore the differentials in tastes of the recipients of the different types of income.

[18] United Nations, Department of Economic Affairs (New York, 1951).

[19] I am particularly indebted to P. N. Rosenstein-Rodan for discussion of the issues raised in this section.

substitution of factors does not seem to fit well the technological characteristics of a number of important industries, as, for example, agriculture. I shall attempt therefore to move toward greater realism by use of a two-sector model (one section with fixed, and one with variable coefficients of production), and investigation of the effects of market imperfections in such a system. To the assumption of limited opportunities for substitution in some industries is added the hypothesis that in many other industries there is a considerable range of variability in the proportions in which factors can be used.

It will be useful to initiate the discussion under the assumption that each of the two sectors produce the same product. Suppose that in Figure 7 the constant-product lines of the fixed-coefficient industry are represented by the lines x_1, x_2, ...[20] and the constant-product lines of the variable coefficient industry by the lines x_1', x_2' . . . .

The output x_1 could be produced by the factor combination and technique represented by point 1 or any of the factor combinations using the variable proportions technique represented by the line x_1'. Moreover, following the reasoning on page 546 above, it is also possible to produce x_1 by simultaneously using both the fixed-coefficients and variable coefficients techniques. All of the lines which could be drawn from point 1 to line x_1' represent a *combination* of methods which would produce output x_1: all such lines fall between the lines 1*a* and 1*b* which are drawn from point 1 just tangent to line x_1'.[21] The "efficiency locus" for specified outputs can be traced out by determining, for given amounts of one of the factors, the minimum amount of the other factor necessary to produce the output. If this is done for output x_1 when very little labor is available it is best to produce by the use of the variable coefficients process alone, a representative factor use for this case is at point *p*. As more labor becomes available the minimum amount of capital required to produce x_1 is found by sliding down the variable coefficients constant-product line to point *a*. Line *a*1 represents different combinations of the variable-coefficients technique located at *a* and the fixed-coefficient process. When the labor available is further increased, the minimum amounts of capital necessary to produce x_1 are found by moving along line *a*1. As labor available is still further increased the line 1*b* is the next segment of the efficiency locus used, for reasons analogous to those given for the use of segment *a*1. Finally, when labor

[20] Although the constant-product lines for the fixed-coefficients sector are drawn in Figure 7 as if only one process is available, the demonstration is perfectly general and its implications are applicable when more than one process is available for the fixed-coefficient industry

[21] I am indebted to R. Solow for the criticism of a previous paper which led to this formulation.

is increased beyond the amount available at point b, again only the variable coefficients method should be used to produce x_1.

Output x_1 could also be produced by process combinations and amounts of factors which do not lie on the efficiency locus, of course. Line $p1$ represents a series of such combinations, using in varying proportions the variable coefficients techniques located at p or n and the fixed-coefficient process located at point 1. Any combination of methods along $pn1$, however, would result in higher costs for x_1 than a method found on the efficiency locus; methods along $pn1$ could also be used to
FIGURE 7

produce larger amounts than x_1. Of course, many lines like $pn1$ could be drawn between $a1$ and the vertical portion of the fixed-coefficient x_1 isoproduct line and, analogously, between $1b$ and the horizontal portion of the fixed-coefficient isoproduct line. Lines like $1m$, of which many could also be drawn, represent combinations of methods which would also produce x_1, but require more of *both* labor and capital than points on the efficiency locus. The boundaries of lines such as $1m$ are the vertical and horizontal portions of the fixed-coefficients x_1 isoproduct line.

Figure 7 embodies the constant-returns-to-scale assumption for both the fixed-coefficients and variable-coefficients method. This is not necessarily the most realistic or relevant assumption, however, nor does the relative position of the two types of curves, or the shape of the variable-coefficients isoquants necessarily correspond closely to reality. It is

useful to recognize other, special cases which may have important empirical significance. In Figure 7, for example, only the extremes of the isoproduct curves of the variable-coefficients technique were a part of the efficiency locus for any particular output, and, as drawn, relatively little substitution was possible at such extremes. It would, of course, be possible to draw figures in which the "efficient" isoproduct ridge lines follow the variable-coefficients lines so as to allow substitution of factors over a considerable range.

The effect of divergent rates of return to scale on the shape and slope of the constant-product ridge lines is illustrated in Figure 8 for
FIGURE 8

one possible set of relations. In the fixed-coefficients process it is assumed that there are increasing returns to scale (shown by decreasing distances between x_1, x_2, x_3, along any ray from the origin). In the variable-coefficients method constant returns to scale are the rule (shown by constant distances between x_1', x_2', x_3', along a ray from the origin). In this example, the efficient isoproduct lines change their shape as output is increased. For output x_1 only the variable-coefficients constant-product line is relevant. For output x_2 the "efficient" isoproduct ridge line involves use of both the fixed and variable-coefficient techniques. Finally, for output x_3, only the fixed-coefficient technique is "efficient" and the ridge lines involving the variable-coefficient method necessarily have a positive slope.

Figure 8 provides the formal basis for some useful deductions. Changes in factor prices which might at one scale of output induce shifts in the proportions in which factors are used, may not induce such shifts at another scale of output or may only produce smaller shifts. Likewise techniques of production not feasible at one scale of production may become mandatory for efficiency at another scale.

In Figures 6, 7 and 8 it is particularly clear that in order for the system to travel along its most efficient production isoquant it is necessary that factor prices be flexible. Factor price rigidities would make parts of the efficient constant-product lines unattainable for profit-maximizing businessmen.

We can now go rapidly through an analysis of the two-sector model hypothesis assuming that each sector produces a different commodity. The geometrical representation of this, using the box diagram technique introduced in the previous section, is provided by Figure 9a. The assumption that for x_1 only two alternative processes are available is maintained for convenience; the resulting production-possibility curves for x_1 are shown by the solid lines. The assumption of variable-coefficients in the production of x_2 is limited to the sector between its ridge lines because at these ridge lines the marginal productivity of one of the factors becomes zero and further input of this factor would have no effect on output.[22]

The production functions for x_1 and x_2 are reproduced in the box diagram in Figure 9b: the dimensions of the box are determined by the factor endowments.[23] Using this box diagram we can trace out the efficiency locus for the two products by repeatingly asking the question, "For a given amount of x_1 what is the maximum amount of x_2 which can be produced?" In the process of tracing out the efficiency locus, the transformation curve can be drawn for the two goods.

Starting at O_1, zero output of x_1, the maximum amount of x_2 producible is given by O_2A. If the output of x_1 is increased relative to x_2, it would be most efficient at first to use process x_1' for x_1 and to produce x_2 by traveling along its most capital-intensive ridge line, O_2A. This represents optimal behavior up to point B. In this stage although both products are being produced capital is a redundant factor. This results in spite of the variability of coefficients in production of x_2 because outside the upper ridge line of x_2 capital has zero marginal productivity. Stage 1 is represented on the transformation curve in Figure 9c as segment AB.

[22] It is assumed that there is no disposal problem and, thus, that the production isoquants do not bend back on themselves.

[23] Again only the ratio of the factor endowments is important as long as constant returns to scale is assumed.
FIGURE 9A
FIGURE 9B
FIGURE 9C

The efficiency locus from B to C is traced out by finding the succession of points at which the x_1 constant-product curves touch the highest x_2 constant-product curves. In this stage process x_1' will be used for x_1 and a varying combination of factors for x_2. The segment of the transformation curve for this stage, BC, will be curved as equal increases in production of x_1 along x_1' will not result in constant changes in output of x_2. Only along rays from the origin O_2 will equal distances imply equal differences in output of x_2. BC will be concave to the origin as is "normal" for transformation curves; graphically it can be seen that smaller and smaller changes along x_1' are needed in order to move across equal changes in output of x_2. As production moves from B to C the points at which x_1' corners touch the x_2 isoquants will be characterized by smaller and smaller slopes on the x_2 isoquants, corresponding to the

decreasing capital-labor ratio used in the production of x_2. At some point, C, the capital-labor ratio in x_2 will become equal to the capital-labor ratio represented by the negatively slanting portion of the x_1 isoquants. A ray from the origin O_2 to point C will intersect every x_2 isoquant at a point with identical slopes. Thus CD, the third stage of the efficiency locus and the transformation curve, will be the series of tangencies of the negatively slanting portion of the x_1 isoquants, representing combinations of processes x_1' and x_1'' and the x_2 isoquants along the ray O_2C. The segment of the transformation curve corresponding to CD lies on a ray from O_2 and thus the equal jumps across the x_1 isoquants will mark out constant changes in production of x_2.

At point D and for further increases in output of x_1 relative to x_2 it would be best to use only process x_1'' for production of x_1. The segment of the transformation curve, DE, corresponding to DE on the efficiency locus, is curved for reasons similar to those which created the curvature of segment BC.

The final stage of the efficiency locus is the labor unemployment stage. The marginal productivity of labor has fallen to zero in the x_2 sector and in a perfect factor market wages would fall to zero. EF represents this final stage on the transformation curve in Figure 9c.

ABCDEF in Figure 9c is the full transformation curve for this case. There are now curved as well as straight-line segments, and the kinks characteristic of the previous transformation curves have disappeared.[24]

In Figure 9b, as in Figure 5b, it is possible to visualize the effects of structural changes by altering the shape and position of the production isoquants for each product and the dimensions of the box.

The box diagram approach helps to clarify the implication of the differences in substitutability in the fixed-coefficient and variable-coefficient sectors. It is clear that the outputs at which one or another factor becomes redundant will be determined by the limits of substitution in the variable-coefficients sector and the most extreme labor- and capital-intensive processes in the fixed-coefficient sector, not by the discontinuities of the latter sector. These have other important effects, however.

Suppose that the respective demands for output are such that a large part of the available capital is drawn into the capital-intensive and fixed-coefficient sector. The amount of labor which can be absorbed in these sectors is dependent on the amount of capital available. Since capital is a scarce factor, labor employment opportunities in this sector are limited by its availability rather than by demand for output.

[24] Being off the efficiency curve, it may be noted is like being on an isoquant **1m** in the single-good case *Cf* Figure 7 above.

The relatively plentiful labor supply is then pushed into the variable-coefficient sector and absorbed there as long as the marginal value productivity of labor is higher than the wages it receives.

In this case, as in the models of the preceding sections, unemployment is not due to lack of effective demand and as a result cannot be relieved by conventional contracyclical economic policy designed to stimulate spending. If employment opportunities in the fixed-coefficient sectors were limited by capital scarcity or some other resource bottleneck, an increase in demand rather than stimulating additional output would only create inflationary pressures. Likewise, in the variable-coefficient sectors if the marginal productivity of labor were zero, the first effects of an increase in demand for output would be an increase in prices without an increase in production. If more of the scarce factors were made available to the fixed-coefficient sectors, more labor could then be employed and would be used, if there were an effective demand for its output. Additional amounts of the scarce factors in the variable-coefficients sector would also increase labor productivity and output if demand were adequate.

It is possible in this case of two sectors, one of fixed and one of variable coefficients, for a divergence to exist between the full-employment output and the output with maximum value, just as in the case of fixed-coefficient processes for each of two goods, as depicted in Figure 6 above. This could result even if there were no market imperfections. If, in Figure 9c, the community indifference curves were like i_1 rather than i_2 so that the tangency occurred in the capital-scarcity, labor-surplus stage, the divergence could exist. On the other hand, community indifference curves shaped like i_2 would mean that it would be possible for full-employment output and maximum-value output to be identical. This demonstration is subject to the same qualifications applied to the one-good case.

Without empirical knowledge, it is not possible to evaluate certainly the relative importance of each of the stages of the transformation curve 9c. However, according to the hypothesis advanced here the transformation curve for underdeveloped areas would consist mainly of the high labor-intensity and labor-unemployment segments such as *DE* and *EF*.

We have thus far in this section assumed the existence of competitive markets and profit-maximizing entrepreneurs. We have shown that, even under such assumptions, technology, factor endowments and final demands may combine in ways which make it very difficult for underdeveloped areas to solve their problems of unemployment and underemployment. It is possible now to broaden the analysis by combining it with the analysis of the effects of market imperfections discussed in

Section I to determine what further problems are created when some of the assumptions of competition are dropped.

Behind the transformation curve lie many fine adjustments as factors are shifted from one industry to another and recombined in varying proportions to obtain the maximum output from one industry for given outputs of the other industry. It has been assumed in deriving the transformation curve that the necessary adjustments would be accomplished as they would be in a perfect factor market. But flexibility within wide limits is required to achieve every possible position on a transformation locus such as that in Figure 9c. When imperfections and rigidities of various types obstruct the movements of factors and prices, the system will not be able to achieve its optimum transformation curve but will instead do no better than to move along some other, less than optimal curve. Limited factor-price flexibility may be quite serious when at least one good is produced with fixed-coefficient processes. If rigid factor prices render a relatively labor-intensive process unprofitable, the only alternative process may involve a big jump to a quite capital-intensive process as well as a drastic obstacle to substitution in the variable-coefficients process.

Since we are interested in the effect of imperfections in the factor markets, it will be useful to distinguish transformation curves which assume perfect adjustments in the factor markets; these will be called "technical transformation curves." Transformation curves which take into account market imperfections will be different from the technical transformation curves; these latter relations will be designated "market transformation curves."[25] Different types of market imperfections will create different types of shifts away from the technical transformation curve, so there is not one market transformation curve for each technical transformation curve but many.

It may help to approximate reality to assume that factor-price ratios in the variable-coefficients sector are relatively more flexible than those in the fixed-coefficients sector. This might result from differential strength of union organization or susceptibility to government wage controls. Suppose, for example, that by means of union pressures or minimum wage legislation real wages of labor were maintained so that in the fixed coefficients sector the labor-capital price ratio was set above that represented by the slope of the constant product curve combining processes x_1' and x_1'' in Figure 9b; the factor-price ratio in

[25] The effect of factor-market imperfections in shifting the market transformation curve inside the technical transformation curve has been pointed out and analyzed for international trade by G. Haberler, "Some Problems in the Pure Theory of International Trade," *Econ. Jour.*, June 1950, LX, 223-40 and by P. Samuelson, "Evaluation of Real National Income," *Oxford Econ. Papers*, Jan. 1950, II (N.S.), 18-19 for welfare economics; others have probably also noted the effect.

the variable coefficients sector may still be assumed to vary freely. The cost-minimizing combination of factors is determined for any particular output at the point at which the production-possibility schedule for that output touches the lowest expenditure line. If the production-possibility schedule has any slope at this point, it is a condition of equilibrium that this slope be equal to the factor-price ratio which determines the slope of the expenditure line. As a result under the present assumptions process x_1'' would never be used. It would always be more profitable to use process x_1' alone in producing x_1. The transformation curve would be *ABCGH* in Figure 9c; this is below the technical transformation curve and has a much longer range of unemployment. If both sectors were characterized by such high, inflexible factor-price ratios, the economy's transformation curve would approach *ABCJ*.[26]

Barriers to the movement of factors would have the effect of moving the market transformation curve even further inside the technical transformation curve and increasing the range over which a factor is redundant.

Thus imperfections in factor markets have several undesirable effects. They reduce the amount of goods available and create a wider range of combinations of goods over which labor may become unemployed, depending on the structure of final demand.

Although the effects of rigid wages on the transformation curve of the economy are clear, welfare judgments as to the results of removal of the factor-price rigidities are subject to the same qualifications as in the previous case. Much depends on the effects of a change in methods on the income distribution and, via income distribution, on community preferences.

III. *Empirical Verification*

The analysis above is based on hypotheses which can be tested empirically and which deserve to be given factual content. Empirical testing requires measurement of the proportions in which productive factors can be and are actually used. Essentially the objective of such research would be an investigation of production functions.

Although the concept of the production function has been familiar for some time, its empirical investigation has, as is common, been neglected with important noteworthy exceptions. In this connection it should be noted that even though it is sometimes presented as an analysis of productive processes and its terminology is taken from the theory of production, input-output analysis, as it now stands, does not reveal

[26] Barriers to capital movement created by monopoly may create situations analogous to those described above resulting from labor-market imperfections.

the technologies actually in use in an economy. For this purpose a much higher degree of disaggregation would be necessary than is currently practiced or appears feasible. Interindustry flows may strongly reflect historical incidents by which certain technical processes are concentrated in a particular sector which subcontracts for other sectors. Or, if similar technical processes are widely used, the interindustry flows in a particular year may reflect different cyclical patterns in industry; one industry producing at its capacity may subcontract to another industry which has equipment capable of performing the necessary operations and is cyclically depressed.[27] Studies of capital coefficients made for input-output tables do indicate, however, a method which can be used for a factor proportions study.[28]

The objective of the process analysis approach newly developed at the RAND Corporation is exactly the empirical determination of production functions. The emphasis of the process analysis approach in establishing all the alternatives on a production-possibility schedule, which is essential for programming, is somewhat different from a factor proportions study. For the latter study not only the range of possibilities but the relative frequencies of their use and dynamic considerations involved in choice are important. The methods of process analysis can also be used for a factor proportions study, however.

For the study of factor proportions two general approaches seem to be available. The first, suggested by input-output studies of capital coefficients and which will be called the "product analysis" method, involves a census in each plant studied of the amounts of each type of factor of production used in the expansion of the output of a particular product. The second method, based on classifications of technical processes, requires the determination of the combinations of factors actually used by firms to perform certain standardized "tasks."

These approaches to the factor proportions study are not necessarily logically separate, nor should they always be completely different in application. The great advantage of process analysis in precise identification of outputs can compensate for the weakness of product analysis where multiproduct plants are involved. The advantage of product analysis in inclusion of all contributing inputs can be important when using the process analysis approach where it is difficult to isolate the contributions of all inputs. Thus, it is important in particular cases to have in mind a method combining both the product and process analyses.

[27] This point is made with force by H. Markowitz in *Process Analysis of the Metal Working Industries*, The RAND Corporation (Santa Monica, 1953), pp. 7-8.

[28] Esp. the studies made by the Inter-Industry Analysis Branch of the Office of Chief Economist, Bureau of Mines, U. S. Department of Interior.

The application of product analysis can be made in two ways: (1) By abstracting the data required from the engineering plans which are prepared when a new investment is undertaken and which list the construction, equipment, labor and materials required for the operation of the plant. Accounting records of new investment expenses could also supply part of the necessary information. (2) By means of "factor inventories" of existing plants to provide for these plants the information which the investment plan analysis provides for new expansions. No easy and automatic application of product analysis techniques is possible in the face of problems such as those raised by multiproduct firms and the measurement of the expansion of capacity. These problems can often be overcome, I believe, to make this a fruitful method.

Process analysis is based on the conception that all productive activity can be divided into separate technical processes with similar outputs whose inputs can be identified and compared. Process analysis thus provides another logically satisfactory approach to study of factor proportions. The process analysis approach can moreover provide the basis for a comparison of factor proportions by final products, and thus for an independent check of factor proportions computed by the product analysis method. This could be achieved by determining the appropriate physical processes and levels of activity necessary for the output of a particular final product and aggregating their factor inputs. The procedure just described is, in fact, that actually used in modern engineering practice in plant and equipment design and layout.

The disadvantage of the process analysis approach, however, stemming from the kinds of information which would be generally available, I believe, occurs precisely where the product analysis method is strong. The information for the process analysis approach must come from the records of inputs to particular processes and these records, because of the purposes for which they are kept, will seldom be sufficiently detailed and comprehensive as to the inputs involved in a process. As a result it will often be necessary in using the process analysis approach to estimate the contributions of "indirect" inputs to the processes studied.

A major source of information for the application of the process analysis approach may be the time cards kept by many firms. These cards list for each worker the time which he takes at each type of machine which he uses to perform the operations on the particular piece. These cards would have the labor inputs and machines specified for particular tasks and often contain other useful data as well. The job sheets which accompany production orders are also sources of information as they list the time per unit and in total required by each type of machine and process to finish a particular item.

IV. *Conclusions*

In this paper a number of different hypotheses have been developed and combined for the purpose of explaining outstanding features of some underdeveloped areas: the persistence of unemployment and underemployment, the coexistence of "modern" capital-intensive techniques and methods using a great deal of labor and little capital, and large differentials in factor returns in different sectors. I have suggested that to a considerable degree these conditions may be the result of a few characteristic conditions: factor-market imperfections, and limited technical substitutability of factors, with divergences between the proportions in which goods are demanded and in which they can be supplied with full use of available factors.

Factor-market imperfections which limit factor mobility create employment problems in underemployed areas with low per capita incomes and limited capital resources which are not different in kind but are much different in degree from those existing in the more advanced countries.

When the proportions in which factors can be combined are variable without limit, *i.e.*, with decreasing but always positive marginal returns to labor, additional labor can always produce additional output. If the technical substitutability of factors is limited, as is suggested here, the possibility of labor redundancy arises. Even if there are some sectors in which labor always has a positive marginal product there may be a divergence between maximum value output and full employment output if there is insufficient demand for the output of these sectors. These possibilities are again more important for the underdeveloped areas whose resource endowments are often not suited to the factor proportions dictated by the technological leadership of advanced countries. Differences in income distribution and the range of products may also make limited technical substitutability a more pressing problem in underdeveloped than in advanced areas.

COTTON MECHANIZATION AND ECONOMIC DEVELOPMENT

By James H. Street*

In formulating a general explanation of economic development, one of the central problems is to account satisfactorily for the disparate rates of growth which have taken place, not only between widely differing cultural regions, but within some of the industrially advanced parts of the world. This problem was recently stated succinctly by Theodore W. Schultz:

> In taking the long view, it is, of course, patent that economic development has occurred very unevenly, not only among countries and major parts of the world but also among communities within an economy or country. The very unevenness of this development presents two basic questions: What particular circumstances give rise to the process of economic development? Why does this process occur so unevenly, more especially, why does it by-pass entire communities within an economy, say within a country having well-established internal trade and migration?[1]

Schultz cites the American South, among other regions, as an example of a community which has been by-passed in this manner, and attributes the lag in economic development of the region primarily to its location relative to industrial-urban centers. The discussion which follows, while not denying a degree of significance to the factor which Schultz emphasizes, seeks to take a more comprehensive historical and theoretical approach to the problem. This paper summarizes the results of a study of the long retardation, followed by a recent sharp acceleration, in the application of mechanized methods of production in the cotton region of the southern United States. (It should be observed that this region does not coincide precisely with the South as a cultural region, though most of the welfare problems associated with cotton production have been concentrated in portions of the Old South. Moreover, while cotton is losing its relative importance as the dominating enterprise in the South, the conditions under which it is produced still exercise a major influence in the rural parts of the region.)

* The author is associate professor of economics at Rutgers University

[1] *The Economic Organization of Agriculture* (New York, 1953), p. 148

An examination of one historical case hardly establishes the basis for a general explanation of regional economic retardation and acceleration; yet it is the writer's belief that the analytical categories applied in this instance, as well as certain of the conclusions, may be useful in considering other cases with similar characteristics. The analysis utilizes three groupings of forces: (1) institutional, (2) technological, and (3) exogenous factors in the process of development. Institutions, while they organize the activities of the community, are in general characterized by inertia and the tendency toward self-perpetuation. Technology, which includes improved theoretical conceptions and productive methods as well as mechanical devices, has a dynamic impact upon existing methods of production and is the chief source of conflict with existing institutional arrangements. Exogenous factors must be considered separately because a regional economy will at times be importantly affected by events originating independently outside the region.[2]

I. *The Cotton Region as an Underdeveloped Area*

The introduction of cotton-growing as a major farming enterprise and regional source of income during the postcolonial period of American development took place under conditions unusually receptive to rapid growth and technological improvement. Events in the raw-materials-producing New World during this period were closely linked to the Industrial Revolution abroad, and for a time partook of the same innovating spirit. While most American crops underwent an extended period of production under conditions of diversified, self-sufficient farming from which they emerged gradually to fill the increasing needs of an urban market, cotton came into its own as a commercial crop almost overnight. As a substitute for the declining tobacco, indigo, and rice enterprises, cotton found waiting for it an established plantation economy with overseas trade connections ready to exploit a new com-

* This article is based on a larger study scheduled for publication in 1956 under the title *The New Revolution in the Cotton Economy*. The present study relies for its basic conceptions primarily upon two sources, the respective analyses of economic development of C. E. Ayres and Simon S. Kuznets. Ayres' penetrating description of the institutional and technological aspects of economic change has been brilliantly set forth in *The Theory of Economic Progress* (Chapel Hill, 1944). Ayres' theoretical framework seems to have been unduly neglected thus far by writers on the theory of economic development. Kuznets' contribution to the factorial method of historical analysis is perhaps more widely known; but his perceptive classroom treatment of the general process of economic development has not appeared in print. The method is exemplified in an early essay on "Retardation of Industrial Growth," recently reprinted in *Economic Change: Selected Essays in Business Cycles, National Income, and Economic Growth* (New York, 1953). The writer must of course accept the responsibility for whatever deficiencies result from the attempt to fuse analytical methods derived from two such vigorously independent minds.

mercial opportunity. The burgeoning British textile industry provided a seemingly insatiable demand for raw cotton, whose spinning and weaving properties surpassed those of wool or flax on the early power-driven spinning machines and looms.

The initial expansion of cotton-growing took place in India and the West Indies, rather than the American South, since the former were more plentifully supplied with hand labor. Two early instances of technological innovation, however, enabled American production to take the lead. The first of these was the invention of the cotton gin. Within two years after the advent of Eli Whitney's saw gin in 1793, and despite his strenuous attempts to establish monopoly control over his invention, gin stands had been set up as far west as the Mississippi, then on the frontier of cultivation. By 1796 Whitney and his partner, Phineas Miller, were operating thirty gins in Georgia alone. Within a decade American cotton output increased eightfold, and sea-island cotton was largely supplanted by the short-staple upland varieties which Whitney's invention made it economically feasible to prepare for market.

A second innovation, hardly less important than the invention of the cotton gin, was the introduction of the Mexican or Petit Gulf variety of cotton to replace the earlier varieties, which were subject to rot and had deteriorated both in yield and quality. The superior Mexican cotton was observed by General James Wilkinson on a mission to Mexico City around 1814. He is said to have evaded the Spanish viceroy's ban on seed exports by stuffing some rag dolls intended for his nieces with the coveted cottonseed and thus smuggling it into Mississippi. The widespread adoption of this variety increased yields sufficiently to permit doubling the amount of cotton that could be picked by a hand in a day.

Short of the development of a few mule-drawn planting and cultivating implements, none of which reduced total labor requirements significantly, there was no other noteworthy improvement in methods of cotton production for well over a century. The invention of the cotton gin merely shifted the acute need for an adequate supply of hand labor from the ginning shed to the field, where two severe seasonal bottlenecks prevailed: the labor needed for weed control and the labor for harvesting. Historically the problem was of course met by the greatly increased importation and domestic breeding of Negro slaves.

A thoroughgoing mechanical solution for this set of problems has been achieved only very recently and as yet in limited areas. Nevertheless, in the 1953 season 22 per cent of the American cotton crop was harvested by machine, and in California machines harvested 59 per

cent of the crop.[8] This is not the evidence, but rather the symbol, of the change. Equally significant is the fact that virtually every other stage of the crop has recently been brought under mechanical control. Total mechanization has become technically feasible only by virtue of a remarkable concurrence of developments in plant breeding, weed control, plant defoliation, and cotton ginning, as well as in perfecting satisfactory mechanical harvesters, of which there are now several distinct types on the market. The introduction of these techniques in combination promises to have profound effects on the economy and the social institutions of the rural South.

The current revolution in production methods may be construed as a belated attempt to catch up with similar movements that occurred earlier in other agricultural enterprises as well as in industry. The lag in economic progress in the Cotton Belt is the more remarkable when one considers that the region has shared with the rest of the country a common language, a common culture, common political institutions, and, increasingly with the years, a considerable interchange of population. Why was the new revolution so long in coming?

The answer appears to be that the American cotton region has shared in an important degree some of the characteristics which are now generally recognized in many industrially underdeveloped parts of the world. These may be summarized as follows:

1. *An intense and highly specialized commercial exploitation of a basic extractive industry requiring little capital investment at the outset, and utilizing abundant undeveloped resources in combination with large quantities of unskilled, routinized labor.* In the case of the South, unlike the typical colonial area, it was not indigenous labor which was so utilized: yet the transplanted African natives who became the American slaves were culturally so primitive and racially so easily distinguished as to lend themselves to ready exploitation under what amounted to a colonial system. It was thus in effect possible to create in the South a labor situation not greatly different from that pre-existing in the more heavily populated colonial areas of the world.

It should be recognized as a point of dissimilarity that the political independence of the American colonies after the Revolutionary War curtailed the opportunity and the incentive for some of the extreme instances of colonial exploitation recorded in those areas that served only to feed the economic interests of a mother country. Furthermore, in the American cotton region the growth of a free white population

[8] U. S. Agricultural Marketing Service, *Charges for Ginning Cotton, Costs of Selected Services Incident to Marketing, and Related Information, Season 1953-54* (Washington, processed, May 1954), p. 2.

which could not be held in check by such devices as the exclusive crown grant likewise permitted an infiltration of yeoman farmers who gave the region a somewhat mixed institutional complexion. Even so, the interests of the dominant groups within and without the South were for a long period not oriented toward a balanced economic development of the region, but toward a perpetuation of the policies identified with colonialism. Commercially, the Cotton South was a colony of the Manchester mills long after the Revolutionary War.

As the economy of the United States became more closely integrated, especially after the Civil War, the South merely tended to shift its complementary relationship of specialization and exchange to a new locus of attachment. Such rail and other transport facilities as were constructed facilitated the maintenance of distinctly industrial and agricultural sections of the country. Though this arrangement was actively promoted by Northern financial and industrial interests and was at times heatedly protested in the South, it was reinforced at almost every point by southern commercial institutions and long-standing habits of thought.

As is well known, the overspecialization represented by the one-cash-crop system (which was not confined to cotton in all parts of the South), led to wasteful depletion of the soil. Because land was cheap and the principal investment was in chattel slaves, the practice arose of "killing the land" of its virgin fertility and moving westward—a practice which was continued long after slavery was abolished. Thus were created cost differentials between the older and the newer parts of the region which have never been overcome.

In light of the increasing diversity of farm enterprises in the South, one wonders at the long insistence that only cotton (or, in certain localities, only tobacco, rice, or sugar cane) could be successfully produced. While it is true that recent changes, such as the growth of urban population, changing dietary habits, improved transport, and other factors have fostered increasing variety in farm enterprises, the fact is that amazingly little attention was given to alternative possibilities until very lately. One is tempted to draw an analogy between the tendency toward economic overspecialization and the principle of evolutionary overspecialization in biology.

2. *The organization of appropriate institutions of control.* These consisted principally of the plantation system; slavery and its successor, the sharecrop system; and the local credit system, with its reliance upon the crop lien and the landlord's "furnish," or advance to the tenant on the prospective crop. All of these are too familiar to require description here, but it is important to note their combined effect on the pattern of income distribution, the maintenance of a stable and abun-

dant labor supply under absolute control, and the mutual reinforcement of the institutional pattern.

The plantation system entailed certain efficiencies which have been well described by Lewis Cecil Gray.[4] These were not, however, primarily economies of scale such as are associated with technologically determined large-scale industry or modern large-scale farming. There are plantations in the South today (though they are rapidly disappearing) that are operated as clusters of small-scale units under virtually independent management as far as the process of production is concerned. The chief advantage of the plantation system stemmed from the powerful means of institutional control over labor, and hence over the distribution of income, which it afforded.

The sharecrop system which emerged to replace slavery after the Civil War was a change in form but not in substance, since its chief purpose was to insure the stability of the labor supply. The local credit system tended to insure the preservation of the one-crop system because credit was hardly available for any other purpose, and by imposing systematic indebtedness on the tenant groups it helped to maintain the existence of a servile, illiterate laboring class regarded as essential to the production of the cotton crop.

This had several unfortunate "boomerang" effects on the South. It meant that during depressed periods in the cotton markets (as in the 1840's, the 1890's, and the 1930's), when it might have seemed desirable to shift to some other form of production, the lack of versatility of the labor force and the rigidity of the credit system impeded such shifts. It meant that immigration into the region by European groups such as those who settled in the Middle West was discouraged, since the new arrivals did not want to compete with slaves and sharecroppers. In the few instances when such migrations took place, as in the case of the German and Bohemian settlements in central Texas and in Alabama, these communities remained culturally isolated islands seemingly unable to influence the general pattern of agriculture even though they successfully practiced general farming of the yeoman type. Finally, it meant that there was little attraction to industry to enter a region where the general income level was so low and the regional economy so dependent on the fortunes of a single enterprise.

3. *Demographic characteristics of a predominantly rural culture which has begun to be affected by technologically more advanced areas.* A commonly noted characteristic of pre-industrial communities is the tendency for the net survival rate to rise as the death rate declines under the influence of modern sanitation and medicine while the birth

[4] *History of Agriculture in the Southern United States to 1860*, 2 vols (Washington, 1933), Vol I, pp. 301-03, 478-79

rate, primarily subject to older habit patterns, falls more slowly. This interesting interplay of technological and institutional forces is reflected in the South, whose rural birth and death rates (particularly among Negroes) have been among the highest in the country. Rupert B. Vance has estimated that during the period 1920-1941 the rate of natural increase in the eleven southeastern states was so great that it would have required an annual net outflow of over 250,000 migrants merely to maintain a stable population.[5] Any reduction in the outflow, such as occurred during the depression years, tended to intensify the problem of providing employment for the increasing population in a predominantly rural region. The result has been a chronic tendency for the South to oversupply itself with farm labor, leading to unemployment and substantial, though less apparent, underemployment.

4. *A failure to make vigorous use of available technological alternatives to customary production methods.* This generalization is more difficult to substantiate than the three preceding, since it is impossible to devise a norm for maximum utilization of available technology, and since there are unquestionably many factors other than mere reluctance to use the inventions that have been made which influence the rate of technological innovation. In the case of cotton production a complex series of technical obstacles had to be overcome before complete mechanization could be regarded as practicable. Cotton as a plant lacks the uniformity and cultural simplicity of the cereal crops and hence must be handled with more complicated equipment. In addition, the sort of technological borrowing which took place in the long stream of inventions from McCormick's reaper to the modern self-propelled grain combine was for the most part not available to the inventors of the cotton picker. Furthermore, the pattern of a resident labor force which had been established in the South made it unsatisfactory to mechanize the harvest without simultaneously providing a solution to the weed problem.

Notwithstanding these considerations, however, it is also fairly clear that the rate of innovation can to some degree be forced by active research and by the vigorous sponsorship of the more enterprising producers in an industry. The development of a successful cotton harvester was hardly delayed for lack of ingenuity and painstaking investigation on the part of aspiring inventors. Most of them received scant support. The principle of the cotton stripper, now widely used in the High Plains of Texas, was known in 1874, but did not arouse serious interest until the critical crop year of 1926, and thereafter only intermittently until the reduction in migratory labor during the second

[5] *All These People* (Chapel Hill, 1945), p. 131.

world war made a technological solution imperative. Roughly prepared cotton, which had previously been unacceptable at the gins and which had entailed an intolerable amount of waste when hand labor was plentiful, now was perforce accepted by farmers, ginners, and spinners alike, even though the latter two groups had to devise special methods to handle it.

The history of the development of the spindle picker, now used extensively in California and increasingly in other irrigated or rain-belt cotton, reveals similar aspects. Angus Campbell, whose pioneer work in the early part of the century established the basis for the machine ultimately put on the market by the International Harvester Company in 1948, spent 37 years working on his invention until his death in 1922. Each harvest season for over twenty years he used his annual vacation time to travel from Chicago, where he was employed by the Deering Harvester Company, to one of the cotton states to try out his latest model. Thus he could engage in only a few brief field trials each year, without access to adequate nearby shop facilities for modifications on the spot. Apparently there was little interest in his efforts, although the principles he worked out later proved to be of fundamental importance. L. C. Stuckenborg, John F. Appleby (the inventor of the twine binder), and Hiram N. Berry also spent long periods working on machines of considerable ingenuity, but with limited backing. John D. Rust, who in association with his brother Mack is generally credited with having devised the first successful spindle picker, conceived his machine in 1927 and had a working model in 1931, but did not see it in commercial production until 1949.

Each inventor was forced in time to realize that there was little prospect for the adoption of a mechanical harvester that would do only a passably good job. It was necessary for the machine to be ***highly*** efficient in the quality of the product it turned out and *overwhelmingly* labor-saving in comparison with hand picking. It must be acknowledged that when the Rust brothers were finally able to develop such a machine, the delay in its commercial introduction was to some degree deliberate on their part. Wishing to avoid the indiscriminate displacement of farm labor that might result from marketing their machine in the conventional way, the Rusts sought for years to safeguard its introduction by devices that would spread its labor-saving benefits among small farmers and tenants, and thus they lost the lead in getting the spindle picker onto the market. (Machines embodying Rust patents are presently being manufactured by two companies under nonexclusive licenses.)

The process of innovation is a complex one fraught with fortuitous

TABLE I.—NUMBER AND PERCENTAGE CHANGE OF FARM TRACTORS, UNITED STATES AND TEN COTTON STATES, 1920–1950

	Number of Tractors on Farms[a]						Percentage of Increase over Previous Date				
	1920 Jan 1	1925 Jan 1	1930 Apr 1	1940 Apr 1	1945 Jan 1	1950 Apr 1	1920–1925	1925–1930	1930–1940	1940–1945	1945–1950

elements. It is the writer's belief, however, that for at least the period since the advent of the tractor the stultifying effect of southern social and economic institutions has been a greater factor than the existence of technical difficulties in explaining the slow rate of progress in the mechanization of cotton production and the lag in the general rationalization of southern agriculture as well. The overriding circumstance in this process has been the availability of a routinized, poorly educated, and politically ineffective rural labor force which for a long period rendered sustained inventive and developmental interest in labor-saving farm machines economically pointless. Until the existing population distribution and the institutional structure embracing it were seriously jarred by the impact of outside events, there was an irresistible predisposition to try to solve the problems of the cotton economy by institutional expedients rather than by technological reorganization.

II. *The Process of Accelerated Change*

The past decade has witnessed a striking increase in the adoption of mechanized methods of production in southern agriculture. In considering cotton production, a distinction must be drawn between partial mechanization, which signifies the introduction of the tractor without a notable reduction in total labor requirements, and complete mechanization, which entails sufficient additional equipment to reduce greatly the man-hours required in the twin bottlenecks, cultivation and harvesting. Complete mechanization will not necessarily follow closely on the heels of partial mechanization, but the latter is often a transitional stage toward the former.

It is therefore highly significant that the number of farm tractors in the ten leading cotton states (excluding California, Arizona, New Mexico and Missouri) rose from 223,300 in 1940 to 743,400 in 1950, an increase of 233 per cent, as compared with a national increase of 130 per cent and an increase in the Nonsouth of 107 per cent. The highest rates of increase were in the southeastern states, where there were relatively few tractors in use prior to the second world war (see Table I). The southwestern states had already experienced substantial rates of increase in tractor numbers during the prewar decade, but continued to add tractors at rates higher than the Nonsouth during the succeeding decade. As a result of these increases, the ten specified cotton states had 20.6 per cent of the tractors in the United States in 1950, as compared with 14.2 per cent in 1940.

Statistics on the newer types of machines are less readily available, but it is estimated that there were about 18,500 mechanical cotton

strippers and 15,500 spindle pickers available for use by 1953.[6] The former had not begun to appear in commercial quantities until 1944, and the latter until 1948. The pattern of introduction of these machines is suggested by Table II, which is based on ginners' reports. It shows that California cotton raisers have led the field in degree of mechaniza-

tion. They harvested 59 per cent of their crop mechanically in 1952 and 1953. Arizona ranked second with 54 per cent in 1953. Texas ranked fourth in percentages (24 per cent), but this represented nearly as much cotton as was mechanically harvested in California. Much of the Texas cotton was harvested with strippers, while the California and Arizona cotton was harvested principally with spindle pickers. The

[6] Estimates prepared by the National Cotton Council of America, Memphis, Tennessee, on the basis of production data provided by manufacturers, and allowing for obsolescence on earlier models.

spindle picker is also coming into significant commercial use in the alluvial areas of Mississippi, Arkansas, Louisiana, and the boot-heel of Missouri, where large fields of high-yielding cotton predominate.[7]

The factors which seem to have been most directly responsible for the recent acceleration in cotton mechanization are (1) the "shaking up" effect of the second world war on the cotton economy, (2) the simultaneous fruition of inventive effort, and (3) the receptive institutional climate in the newer cotton areas.

1. *The effects of the second world war on the cotton economy.* The second world war, which must be treated as an exogenous influence on the cotton region, created highly disturbing effects which for a time severely intensified the uncertainty of producers' decisions. At the same time, however, it brought certain benefits which may be attributed to the general "shaking up" received by the enterprise.

The initial effect of the outbreak of hostilities in Europe in the fall of 1939 was unfavorable to cotton. Exports fell off sharply, and although domestic consumption rose to unprecedented heights after the United States entered the war, surpluses began to pile up in nearly all cotton-producing countries to the extent that, at the beginning of the 1945 crop season, the world carry-over reached 26½ million bales. This carry-over, an all-time record, was equivalent to one year's normal world growth and consumption. Of the total, 45 per cent was American cotton.

Cotton acreage in cultivation declined almost continuously from year to year during the war, yet yields proved exceptionally high, and average annual production in the United States for the 1940-1944 period was about what it had been in 1938 and 1939. A considerable number of southern farmers were induced to make radical enterprise adjustments during these years, such as entering feed and livestock production, and many of these shifts were preserved during the postwar period.

The war also had severe effects on farm population. The combined result of military inductions, migration to other regions, and movement from farm to nonfarm areas was the sharpest reduction in farm population ever witnessed in this country within a similar period. The South was the region with the heaviest losses, experiencing a 20 per cent decline in farm population from 1940 to 1945. Nearly half of the decline took place within one year (1942).[8] Although there are grounds

[7] As will be noted below, a considerable variety of additional equiqment is needed to achieve complete mechanization, but reliable figures on the manufacture and distribution of this equipment are not readily available.

[8] U. S. Agricultural Marketing Service, *Farm Population: Annual Estimates by States, Major Geographic Divisions, and Regions, 1920-1950 and the United States, 1910-1950* (Washington, 1953), pp. 12-14.

to question whether this population outflow was sufficient to create a condition of actual labor unavailability on cotton farms in the South after the postwar readjustments had taken place, the large and rapid shifts of population during the war years undoubtedly had an unsettling effect on producers who had traditionally depended on an abundant supply of low-cost resident labor.[9]

The pessimistic outlook for cotton at the end of the war was further aggravated by the knowledge that synthetic fibers had made heavy inroads on long-standing markets for cotton (particularly in the automobile tire industry), and by the widespread belief that there would be a business recession in the United States following the war. These and related considerations led the Pace Committee to conduct an intensive investigation into the postwar problems to be faced by the cotton enterprise and to sponsor a broad research program later reflected in the Research and Marketing Act of 1946.[10]

Paradoxically, in the face of these discouragements, some of the more favorably situated cotton farmers found it possible to undertake partial mechanization for the first time during the war years. For this an increasingly favorable price-cost relationship was chiefly responsible. Although southern farm incomes remained low in comparison with those in other regions and pursuits, they rose greatly relative to what they had been. And notwithstanding the fact that tractors rarely relieved the most pressing labor stringencies on the farm, there was a strong impetus to begin to catch up with the more "progressive" farmers who owned tractors. The war thus caused many operators who had previously not seriously entertained the idea of converting their farms to become machinery-minded.

Postwar developments contributed to this possibility. The record carry-over of 1945 was worked off in a surprisingly short time, as a result of short crops in 1945 and 1946 and an unexpectedly high demand for cotton both at home and abroad. The latter resulted from the sustained high level of consumer incomes and the government's various foreign-assistance programs. The Korean outbreak prolonged the period of unusual consumption rates for cotton and the price rose so rapidly as to lead to the imposition of a ceiling on the price of raw cotton for the first time. These factors created an unusually favorable climate for the sale of farm machinery in the Cotton Belt.

2. *The simultaneous fruition of inventive effort.* It has often been

[9] See the writer's "The 'Labor Vacuum' and Cotton Mechanization," *Jour. Farm Econ.*, Aug. 1953, XXXV, 381-97.

[10] U. S. House Committee on Agriculture, *Study of Agricultural and Economic Problems of the Cotton Belt*, Hearings before the Special Subcommittee on Cotton, 80th Cong., 1st Sess., 2 parts (Washington, 1947)

pointed out that the development of a satisfactory cotton harvester would not in itself be likely to lead operators in the humid parts of the cotton region to mechanize, in view of the important secondary bottleneck of weed control. So long as it was necessary to maintain a resident labor force for weeding and thinning, it was argued, the same labor could be used for hand picking. To displace it by machines only in the peak season would be both uneconomic and hazardous to the crop if the labor should leave for fuller employment elsewhere.

The past few years, however, have seen a great variety of distinct approaches to weed control culminate in a concerted and largely successful attack on the problem. By various combinations of available methods—which include planting to a stand, cross cultivation, use of the rotary hoe, sweep cultivation, flame weeding, and application of pre- and post-emergence chemical herbicides—it is now possible, or shortly will be possible (depending on the area), to reduce cultivation to a mechanical process.

The cumulative character of technological development is further illustrated by the fact that new varieties of cotton are now being bred to facilitate the use of mechanical harvesters; chemical defoliants are used to remove the plant leaves before picking; a topping machine is used to reduce the size of rank cotton on irrigated land; gins have been redesigned to dry and clean mechanically harvested cotton; and spinners are adapting their methods to utilize the modified product. Nearly every one of these achievements represented a formidable obstacle a few years ago, but problem after problem has responded to research once a strong conviction became established that mechanization was on its way.

The labor-saving aspect of total mechanization, where it has been put into effect, is substantial. In the Mississippi Delta under the traditional system of mule power and half-row equipment, with all weeding, thinning and picking done by hand, approximately 155 man-hours of labor have been required to produce a bale of cotton. By mechanizing as completely as possible with equipment available in 1950 (tractor land-preparation, rotary hoe, flame weeder, and spindle picker) this could be cut to 30 man-hours, which allows for some hand labor to remove weeds in wet seasons. When an assured method of weed control is developed, it is expected that the labor requirement to produce a bale of cotton in this locality can be reduced to ten or twelve man-hours.[11]

3. *The receptive institutional climate in the newer cotton areas.* In surveying the Cotton Belt, one cannot fail to observe that the most

[11] Grady B. Crowe, "Farm Mechanization Research in the South," *Agric Econ Research*, Jan. 1951, III, 6.

rapid rates of introduction of full mechanization are occurring in the newer areas of the Far West and Southwest. These are in general more productive areas than most of the older cotton region, and they are less subject to the weed problem. However, more significance probably attaches to the fact that, as younger areas, they have escaped the encrustation of institutions which has inhibited change elsewhere. Since sharecropping never became established here, there have not been the problems of excessive resident population, small farm units, and depleted soil associated with this system in the Old South. When the usual numbers of migratory workers failed to appear in the High Plains during the war years, farmers almost immediately set about devising mechanical alternatives in the local blacksmith and welding shops. It is significant that the smaller farmers, who were least able to attract migrant workers, were prominent in this movement.

There are other, less tangible, indications that southwestern farmers have not been as tradition-bound in their attitude toward newer methods of farming. Part of the explanation no doubt lies in the circumstance that, having more resources, farm operators in the western parts of the belt had larger cash incomes and therefore greater flexibility in trying new methods. But the fact remains that in the older cotton areas even the larger, well-financed operators on good land did not as a group show the same aggressiveness in promoting mechanization that was already evident in the West before the war, and only recently have their attitudes been changing.[12]

Some highly significant transitional changes in tenure arrangements have been taking place in the Southeast and Mid-South as plantation operators have entered the era of partial mechanization. Most of the larger farms were formerly operated with sharecroppers, but increasingly some combination of share and wage hire is used. Under one type of transitional arrangement, each cropper family is given a small sharecrop, insufficient to provide adequate income for the year, but intended to induce the family to remain located on the farm and to see the crop through. For the remainder of its income the family is dependent on work for day wages. This arrangement has the advantage for the employer that it provides relative stability of the labor supply while not obligating him to provide continuous employment for the entire force. Thus it lends flexibility to his operations as mechanization is introduced by degrees.

Another device is based on the old practice on some plantations of

[12] A few operators have been notable exceptions. Their willingness to experiment and to incur losses with the early machines was important in the ultimate adaptation of these techniques to local conditions.

working the land "through and through," or under a gang system directed by an overseer. Each family is assigned a definite crop acreage, but instead of tending individual plots, all hands work the plantation land in common. This facilitates the use of tractors for ground breaking and seedbed preparation, followed in some instances by mechanical planting and cultivation. Since the planter thus increases his share of the production inputs, he may charge his croppers service fees for the operations performed with power equipment, or change the share ratio from the traditional 50-50 to a 60-40 basis. A few of the tenants are provided with preferred employment as tractor drivers or mechanics at day rates considerably higher than those prevailing for ordinary labor.

A third variation divides the plantation force into two parts: (1) a basic crew sufficient to insure weed control, stabilized on the farm by being assured a sharecrop; and (2) the remainder of the employees, who are on a wage status and whose employment fluctuates with the demands of the season and the year. The members of the latter group have little job security and are most readily detached as mechanization reduces the need for hand labor or as alternative opportunities pull them away from the farm.

These transitional arrangements reflect the reluctance of a number of farm operators to commit themselves wholly to a wage system and a permanently reduced labor force until they "see where mechanization is going." In some cases they have been compelled to alter traditional arrangements by the departure of farm workers for other employment; in other cases the changes are cautious voluntary ventures into the uncertainties of a radically different way of farming. Here and there an operator makes the final plunge into complete mechanization and replans his operations throughout. Vacant tenant houses are pulled down, farm lay-outs are consolidated, the training of a technically competent labor force is undertaken, and every operation from residue disposal of the old crop to the harvesting and processing of the new crop is planned with mechanized handling in mind. This is indeed a great change, and once made it is virtually irreversible.

It is doubtful whether such methods as these can be effectively used on the very small farms still to be found in many parts of the South, though it does not follow that only the large factory farm can become efficient. It is clear in any case that complete mechanization requires a considerably higher degree of technical and managerial skill than has characterized cotton production in the past. This will undoubtedly intensify the competitive strains within the enterprise between low- and high-cost producers, and will thus pose some difficult questions for public

policy. But at the same time it should significantly increase the productivity of farm labor, with all that that signifies for increased standards of income and welfare within the region.

III. *Conclusions for Theory*

The process of mechanization now under way has many implications for the cotton enterprise which cannot be elaborated here. Nor has it been possible to take adequate note of the many other changes simultaneously taking place in the regional economy of the South, one of the most significant of which is the growth of nonagricultural industry with its increased alternative economic opportunities for farm labor. Limited as the investigation is, however, it serves to illustrate that, after due allowance for exogenous influences has been made, the same forces which affect rates of growth in larger economies may explain differences within and among regional enterprises.

The first of these forces is the power of institutions to inhibit progressive change even though they may afford a liberalizing environment at the onset of a period of innovation. While the tendency of institutions to rigidify into a complex structure of mutually reinforcing controls has been documented in countless instances, it is surprising how often this aspect of economic development is overlooked or lightly dismissed in theoretical discussions of factors making for differential rates of change. Now that induced economic development is the order of the day, a study of the circumstances under which institutions become permissive of change must be accorded a place in the strategy of planning. Lately it has become the special province of anthropologists to advise economists, administrators, and technicians in this area, as it was once their role to call attention to the problem.[13]

The second, and in general initiating, force is the compelling quality of technological innovation which, though it may be long delayed by technical circumstances or inhibiting institutions, inevitably forces adjustments in such institutions. This is especially likely to happen when simultaneous inventions and improvements from a variety of sources come together in such a way as to supplement each other with explosive force.[14] The case of cotton production also emphasizes the importance of the opportunity (or absence of opportunity) for technological borrowing in speeding up the process of invention. This is but an aspect of the general principle of technological continuity.

[13] *Cf. Cultural Patterns and Technical Change*, edited by Margaret Mead (Paris, UNESCO, 1953).

[14] The Industrial Revolution in England is the outstanding example of such a combination of previously unrelated elements. Ayres has shown the significance of the same process as it occurred in printing and shipbuilding, *op. cit.*, Ch. 7.

The third force, particularly applicable to preindustrial communities, is what may be called the unassimilated population factor. A high rate of population growth, which is itself a result of previous technological influences in combination with a lag in institutional adjustments, may inhibit further economic improvement. Kuznets has commented on the difficulty of inducing industrialization in areas with a very high population density such as the Far East, where the sheer mass of humanity limits the expansion of transportation and related facilities. American experience has shown that even much more moderate differentials in population density and growth may have significant regional effects. The strategy of planned development requires attention to population relocation both in respect to the effects on the migrants and to the effects on retarded enterprises. Our experience with rural resettlement and land-use planning in the 'thirties illustrates the complexity of these problems.

It must be emphasized in conclusion that it has not been the purpose of this paper to draw a close historical parallel between conditions in the American cotton belt and those in regions of differing cultural and geographic characteristics. Rather the aim has been to utilize the wealth of statistical and other descriptive data which are now available with regard to one area to arrive at the most general considerations which may have application to other areas. In each region the special circumstances and events will no doubt be different, while the contending forces are essentially the same.

SPATIAL EQUILIBRIUM MODELS OF THE LIVESTOCK-FEED ECONOMY

By KARL A. FOX AND RICHARD C. TAEUBER*

During the past three or four years several articles have appeared on the theory of spatial equilibrium.[1] So far, however, only one empirical application seems to have been published.[2]

The closely related "transportation model" has won a prominent place in the linear programming literature and has been applied successfully to the shipping problems of some industrial concerns. In this model, specified quantities of a commodity are to be shipped from each of a number of sources and other specified quantities are to be received at each of a number of destinations, total receipts being equal to total shipments. The receipts at each market are determined in advance and do not depend upon price. The objective is to satisfy the set of destination requirements at the least possible total transportation cost. The "contract award model" is quite similar except that total supplies at shipping points exceed total destination requirements, and the problem is to allocate purchases in such a way as to fill destination requirements at the lowest possible total delivered cost (f.o.b. cost plus freight). This model has been applied successfully to some purchasing programs of the federal government; and similar problems must arise in the procurement operations of private concerns.

The "spatial equilibrium model" differs from these in that prices at each shipping point and destination are continuous functions of the quantities shipped or received plus the quantities produced and retained locally. The spatial equilibrium model, with its price-dependent demand and supply functions, may be quite useful in analyzing problems of public policy, most of which arise at the industry level. These include

* The authors are associated with the Council of Economic Advisers and the Institute of Statistics, University of North Carolina, respectively. The research underlying this article was done while they were employed in the Division of Agricultural Economics, U. S. Department of Agriculture

Department of Agriculture, Bureau of Agricultural Economics, Feb. 1952 (hectographed); M. Beckmann, "A Continuous Model of Transportation," *Econometrica*, Oct. 1952, XX, 643-60; S. Enke, "Equilibrium among Spatially Separated Markets: Solution by Electric Analogue," *Econometrica*, Jan. 1951, XIX, 40-47; P. A. Samuelson, "Spatial Price Equilibrium and Linear Programming," *Am. Econ. Rev.*, June 1952, XLII, 283-303.

[2] K. A. Fox, "A Spatial Equilibrium Model of the Livestock-Feed Economy in the United States" *Econometrica*, Oct. 1953, XXI, 547-566.

tariff and other policies affecting international trade, excise taxes, freight-rate regulation, farm price-support policies, and perhaps others. The competitive organization and continuously varying prices in many agricultural commodity markets make these particularly adaptable to analysis by means of the spatial equilibrium model. The existence of a considerable body of empirical demand analyses for farm products is also a favorable factor.

The present paper attempts three things: (1) It expands the empirical model previously mentioned into a more complex one involving two related commodities and applies it to the analysis of changes in freight rates and in various "outside" factors; (2) it appraises the results obtained from this model in relation to those provided by simpler approaches; and (3) it presents some general conclusions as to the applicability of spatial equilibrium models to other commodities and to other types of market structures.

The spatial equilibrium problem for a single commodity has been stated by Enke as follows:

> There are three [or more] regions trading a homogeneous good. Each region constitutes a single and distinct market. The regions of each possible pair of regions are separated—but not isolated—by a transportation cost per physical unit which is independent of volume. There are no legal restrictions to limit the actions of profit-seeking traders in each region. For each region the functions which relate local production and local use to local price are known, and consequently the magnitude of the difference which will be exported or imported at each local price is also known. Given these trade functions and transportation costs, we wish to ascertain: (1) the net price in each region, (2) the quantity of exports or imports for each region, (3) which regions export, import, or do neither, (4) the aggregate trade in the commodity, (5) the volume and direction of trade between each possible pair of regions.[3]

Enke showed that this problem could be solved by "a relatively simple electric circuit."[4] Samuelson treated the same problem on a strictly mathematical basis, and stated that it could be solved "by trial and error or by a systematic procedure of varying shipments" in the direction that ultimately maximizes a certain function. Baumol independently arrived at results similar to Samuelson's. Beckmann formulated the spatial equilibrium problem in terms of continuous distributions of production density and transportation costs.

The first section of this paper extends the Samuelson or Baumol type of approach to an empirical model of the livestock-feed economy in

[3] *Op. cit.*, p. 41.

[4] However, a 10-region model for a single commodity would require 90 rectifiers and numerous batteries and resistors.

the United States. Livestock and feed products account for 60 per cent of total cash receipts from farm marketings, and livestock products account for about an equal percentage of retail expenditures for food. The importance and complexity of the livestock-feed economy are such as to justify the development of rather sophisticated models to appraise government policies and to keep current economic developments under review, as in the outlook and situation reports of the federal Department of Agriculture.

In the earlier article by Fox, the United States was divided into ten regions whose boundaries were defined in rough accordance with differences in the types of livestock and feed production which were given emphasis in them.[5] Each region was a group of states, as the basic data were published by states. The model included a demand function for feed in each of the ten regions and a structure of freight rates or transportation costs between all possible pairs of regions. Livestock numbers and prices in each region were taken as given or predetermined quantities, as was feed production. The analysis was limited to solving for the price and consumption of feed in each region and for the pattern and volume of interregional shipments of feed.

In contrast, the present model treats livestock prices and production in each region as mutually dependent variables. It includes demand and supply functions for livestock products in each region and a set of interregional freight rates for livestock products. The complete solution for any set of values of given variables (including feed production) must yield (1) prices, production and consumption of livestock products in each region and the pattern of interregional shipments of livestock products, and (2) prices and consumption of feed in each region and the pattern of interregional shipments of feed.

I. *Data and Assumptions of the Expanded Model*

The differences between the earlier model and the one presented below can be summarized in the following sets of equations:

A. Previous Model

Demand for feed:

(1.1) $$p_c = f(q_c, z_h^*, p_h^*)$$

Supply of feed:

(1.2) $$z_c^* = k$$

[5] The regional breakdown was adapted from a standard grouping developed in the former Bureau of Agricultural Economics, based on the dominant types of livestock farming carried on in different parts of the country. The adaptation consisted in combining certain of the BAE regions, reducing the total number from twelve to ten. Use of regions rather than states greatly reduced the computational burden; further, as each region was a group of similar states, most of the relevant differences among states were reflected in the differences among BAE regions.

"Gross" equilibrium condition for feed:

(1.3) $$\sum_{1}^{10} q_c = \sum_{1}^{10} z_c^*$$

B. Present (Joint) Model

Demand for feed:

(2.1) $$p_c = f\ (q_c,\ z_h,\ p_h)$$

Supply of feed:

(2.2) $$z_c^* = k$$

Demand for livestock:

(2.3) $$p_h = f\ (q_h,\ n^*,\ y^*)$$

Supply of livestock:

(2.4) $$z_h = f\ (p_h,\ p_c)$$

"Gross" equilibrium condition for feed:

(2.5) $$\sum_{1}^{10} q_c = \sum_{1}^{10} z_c^*$$

"Gross" equilibrium condition for livestock:

(2.6) $$\sum_{1}^{10} q_h = \sum_{1}^{10} z_h$$

In these equations, the variables have the following significance: p_c = price of feed; q_c = consumption of feed; z_h = production of livestock in terms of grain-consuming animal units; p_h = price of livestock; z_c = production of feed; q_h = consumption of livestock; n = human population; and y = disposable personal income per capita.

Variables marked with an asterisk in any equation are "predetermined"—that is, they are assumed to be given numbers. The "gross" equilibrium conditions simply specify that total consumption must equal total production for the United States as a whole. In addition to these, each of the two models includes the more intricate and detailed equilibrium conditions which determine the pattern of interregional trade and regional price differentials. Except for the "gross" equilibrium conditions, the models include an equation of each type (demand and supply for feed and for livestock) for each of the 10 regions. Thus, if the supply "functions" for feed are counted, the present model includes 40 equations in addition to various equilibrium requirements.

Despite the greater complexity of the new joint model, in practice it was not difficult to manipulate it and obtain solutions using ordinary desk calculators. Once an initial joint equilibrium pattern was determined under approximate 1949-50 conditions, it was found possible to obtain equilibrium solutions for other sets of initial conditions (such as a severe drought) within two or three hours—sometimes less if the initial source-and-destination pairings for feed were not disturbed.

Freight rates and basic data. It has been noted above that three variables in the joint model, namely feed production, human population, and disposable income per capita, are taken as given numbers. The values of these variables for each region, at levels appropriate for the 1949-50 feeding year, are shown in Table I. In addition, column 2 of this table contains the numbers of grain-consuming animal units in each region during 1949-50. This variable was used along with the other three in establishing the level and arithmetic slopes of the demand curves for livestock products and feed in each region.[6]

The structure of freight rates for feed is shown in Table II. These freight rates were estimated on the basis of data on freight charges by mileage blocks from the 1950 ICC waybill sample.[7] They are not

[6] Regional data on production of *feed* (actually feed grains and other concentrated feeds) are based on R. D. Jennings, *Feed Consumed by Livestock, 1949-50;* U.S.D.A. Stat. Bull. No. 145, June 1954.

Livestock production in the model is stated in terms of grain-consuming animal units. This series is constructed by weighting numbers of each class of livestock in each state by estimated feed concentrate requirements per animal under normal feeding practices in that state. The weights used are based on feeding practices as of 1941.

The *livestock price* series has no standard published counterpart. The coefficients relating it to other variables are realistic (according to statistical analyses) whether it is regarded as an index of prices of grain-consuming livestock only or of all livestock and livestock products. The level of this series was set in relation to that of the feed price series in rough correspondence with average hog-corn price ratios—between 12:1 and 13:1. The absolute level is arbitrary; its function in the model is that of a price index.

[7] Freight rates are a special problem in the present model because it is implicitly assumed that production and consumption of feed in each region are concentrated at a single point. As these points are mathematical fictions, the determination of appropriate freight charges between regions becomes somewhat arbitrary. One possibility would be to obtain specific railroad freight rates for corn between cities located near the center of feed production in each region. This would be expensive and time consuming, particularly if specific rates were to be calculated over unusual freight paths, as between two strongly deficit regions. The alternative chosen seems adequate for an exploratory study such as this.

It is assumed in Table II that the freight rate between any two regions is the same in both directions. This is frequently not true in practice and is not necessary for a solution of the spatial equilibrium system presented here. Also, it seems necessary for completeness to estimate freight rates between regions which are quite unlikely to have direct dealings with one another in the form of transportation of feed. Since these unusual or improbable paths of interregional shipment rarely figure in the equilibrium solution, the principal requirement is that the assumed freight rates for such paths be reasonably high, even though they may be lower than the specific rates which might be charged if someone wished to make an actual shipment between the regions in question. The distances under-

[b] Adapted from published data on income payments to individuals by States by applying the published ratio of disposable income to income payments for the United States as a whole.

actual freight rates between specific points but are based on the following equations:

$$X_{ij} = 5.6 + 0.0168\, M_{ij} \qquad (3.1)$$

$$X_{ij} = 5.6 + 0.0224\, M_{ij} \qquad (3.2)$$

$$X_{ij} = 5.6 + 0.0280\, M_{ij} \qquad (3.3)$$

where X_{ij} represents the freight rate on corn from Region i to Region j, in cents per bushel; and

M_{ij} represents the distance in miles between centers of grain-consuming livestock production in Regions i and j.

Equation (3.1) was used where the ICC data indicated relatively low

lying freight rates estimated from the equations are the shortest highway mileages between certain cities located near the center of livestock production in each region.

Equations (3.1) through (3.3) were chosen after examining the regressions of freight charges upon lengths of haul within and between a number of railroad territories. Moderately different equations could have been chosen without doing violence to the basic data or materially changing solutions obtained from the completed model.

[a] Estimated from equations shown in text, not actual freight rates.

[b] Involves shipment by way of the Corn Belt. For example, the freight rate from the Northern Plains to the Northeast is equal to the sum of freight rates (1) from the Northern Plains to the Corn Belt and (2) from the Corn Belt to the Northeast. Shipment over this "indirect" route is cheaper than the "direct" route cost of $0.3618 as estimated from equation (3.2).

freight rates for corn in the railroad territories involved; equation (3.2) was used where an intermediate level of freight rates was indicated; and equation (3.3) was used where the data suggested a relatively high level of freight rates on corn as well as for all paths over which actual shipments of corn were improbable or rare.[8]

The freight rates for livestock (Table III) were similarly derived, using the following equations:

$$X_{ij} = 30 + 0.07\, M_{ij} \tag{4.1}$$
$$X_{ij} = 30 + 0.08\, M_{ij} \tag{4.2}$$
$$X_{ij} = 30 + 0.09\, M_{ij} \tag{4.3}$$

where X_{ij} represents the freight rate on livestock from Region i to Region j in cents per 100 pounds and the M_{ij} are the same as for feed.[9]

Demand and supply functions. For the United States as a whole, the model may be represented by the following equations:[10]

Demand for feed:

$$P_c = -0.7497 - 0.022353\, Q_c + 0.016253\, Z_h + 0.1250\, P_h \tag{5.1}$$

Supply of feed:

$$Z_c^* = 120.78 \tag{5.2}$$

Demand for livestock:

$$P_h = 35.2793 - 0.20226\, Q_h + 0.01111\, Y^* \tag{5.3}$$

Supply of livestock:

$$Z_h = 166.122 + 3.9700\, (P_h - 8\, P_c - 6) \tag{5.4}$$

"Gross" equilibrium conditions:

$$Q_c = Z_c^* \tag{5.5}$$
$$Q_h = Z_h \tag{5.6}$$

The arithmetic coefficients of the demand functions are adapted from

[8] In several cases, freight rates estimated from equations (3.3) or (3.2) proved to be higher than the sum of freight rates from Region i to the Corn Belt and from the Corn Belt to Region j, as most of the latter rates were estimated from equation (3.1). In these cases, the cost of shipping over the cheaper "indirect" route is taken as *the* freight rate from Region i to Region j.

[9] These rates were based on ICC data for live animals (hogs, cattle, and sheep) partly because data on other types of livestock products were limited and partly because the livestock price series used in the model was set at a level appropriate for live hogs.

[10] Capital letters are used in equations (5.1) through (5.6) to denote totals or averages for the United States as a whole; lower-case letters are used in equations (1.1) through (2.6) to denote values for individual regions. Units of measure for Z_c^*, Z_h, n^*, and y^* are indicated in Table I. P_c represents the price of corn in dollars per bushel (56 pounds) and P_h represents the price of livestock in dollars per 100 pounds, liveweight.

[a] Estimated from equations shown in text; not actual freight rates.

[b] Involves shipment by way of the Corn Belt. For example, the freight rate from the Southern Plains to the Northeast is equal to the sum of freight rates (1) from the Southern Plains to the Corn Belt and (2) from the Corn Belt to the Northeast. Shipment over this "indirect" route is cheaper than the "direct" route cost of $1 8668 as estimated from equation (4.3).

logarithmic analyses reported in an earlier article.[11] Equation (5.1) implies that the elasticity of demand for feed is −0.5 and that feed consumption tends to increase in direct proportion to livestock production. The coefficient of P_h in this equation assumes that about 8 bushels of feed (corn equivalent) are normally required to produce 100 pounds liveweight of livestock, and that, other things being equal, a given increase in the price of livestock per 100 pounds would be associated with an increase one-eighth as large in the price of feed per bushel. Equation (5.3) implies that the elasticity of demand for livestock is −0.5 and that livestock consumption increases about 0.45 per cent for each 1 per cent increase in disposable income per person. These percentage relations apply precisely only when the price of feed is set at $1.35 per bushel and the price of livestock at $16.80 per 100 pounds.

Equation (5.4) implies an "equilibrium" livestock production of 166.122 million units if the price of livestock per 100 pounds is equal to 8 P_c (the cost of 8 bushels of corn) plus $6.00, which is presumed to cover nonfeed costs of producing livestock. If the price of corn is $1.35 per bushel, the equilibrium price of livestock is $16.80 per 100 pounds. This relationship is about right if we think of "livestock" in terms of hogs, which are by far the largest consumers of feed concentrates. At the equilibrium prices specified, the price of livestock is 12.44 times the price of feed, or very close to the long-term average hog-corn price ratio.

Coefficients of the livestock supply equations were varied regionally on the basis of the relative importance of different classes of livestock and fragmentary information on supply elasticities for each class. The resulting elasticities of livestock supply ranged from 0.50 and 0.45 in the Corn Belt and Northern Plains regions, where the relatively flexible hog- and cattle-feeding enterprises predominate, to 0.25 in the Northeast and Pacific regions where fluid milk and eggs are the principal grain-consuming livestock products. In all other regions an intermediate figure of 0.35 appeared reasonable.[12]

[11] K. A. Fox, "Factors Affecting Farm Income, Farm Prices and Food Consumption," *Agr. Econ. Research*, July 1951, III, 65-82.

[12] Supply elasticities are best defined in relation to the particular time intervals allowed for response. Supply coefficients in the present model allow (perhaps liberally) for the sort of adjustments which might take place within a given feeding year. It would be better for some purposes to use a lagged model such as that developed on the national level by R. J. Foote. ("A Four-equation Model of the Feed-livestock Economy and its Endogenous Mechanisms," *Jour. Farm. Econ.*, Feb. 1953, xxxv, 44-61). In such a model, livestock numbers and prices would be taken as predetermined variables in solving a feed model applicable to the early part of the feed-marketing year, during which the livestock economy would have little opportunity to respond to the new feed harvest. The

Arithmetic demand and supply functions for each of the 10 regions were then specified in such a way as to reflect the price flexibilities and supply elasticities defined above under certain standard conditions ($p_c = \$1.35$, $p_h = \$16.80$, z_h at the levels given in Table I, column 2, and q_h at the United States average level of per capita livestock consumption.) It was necessary to choose arithmetic demand and supply functions, as the various equilibrium conditions are all in arithmetic terms.

The resulting regional demand functions for feed are shown in Table IV, the demand functions for livestock in Table V, and the supply functions for livestock in Table VI.

II. *Equilibrium Solutions*

A necessary requirement for competitive equilibrium is that no individual can make a profit by shipping additional quantities of either feed or livestock from one region to another. If one region ships to another, the prices must differ by the amount of the intervening transportation costs. If two surplus regions ship to the same deficit region, the difference between equilibrium prices in the surplus regions will be

early-season prices of feed and livestock would then be taken as predetermined variables in solving for livestock production and prices in the latter part of the marketing year.

Longer-run incidence problems could be handled in a simultaneous model like that of the present paper. However, the regional supply functions would probably be based on long-run profit considerations rather than upon empirical studies of supply response. The present model also disregards speculative and other factors which might affect livestock and feed prices during periods materially shorter than a year.

TABLE V.—REGIONAL DEMAND FUNCTIONS FOR LIVESTOCK UNDER APPROXIMATE 1949–50 CONDITIONS
(in million units)

Region	Constant Term	Change in Livestock Consumption per Unit Change in:	
		Livestock Price	Per Capita Disposable Income

United States	174.4246	−4 9441	054929

equal to the difference between their freight rates to the deficit region. Thus, an equilibrium solution implies for each commodity a precise structure of regional prices bound together by specific freight rates, except for regions which prove to be self-sufficient under the given conditions.

To solve the feed model represented by equations (1.1) through

TABLE VI.—REGIONAL SUPPLY FUNCTIONS FOR LIVESTOCK UNDER APPROXIMATE 1949–50 CONDITIONS
(in million units)

(1.3), we can select by inspection a trading arrangement which looks reasonable, even though it will not necessarily prove to be the equilibrium arrangement. (An "arrangement" simply specifies which regions ship or do not ship to which other regions.) The assumed trading arrangement implies a perfectly definite structure of price differentials in which any one regional price can be taken as the basing point. In practice, the Corn Belt was taken as the basing point and feed prices in other regions were lined up in accordance with their differentials above and below an assumed price in the Corn Belt. Then, using the specified demand functions for feed in each region, the consumption of feed in each of the 10 regions was calculated on the basis of the assumed price in the Corn Belt (in this case $1.40 per bushel). The total feed consumption at this level of prices did not exhaust the available supply—that is, it did not meet the "gross" equilibrium condition. Since the assumed rigid structure of price differentials made total United States feed consumption a linear function of the Corn Belt price, the price adjustment needed to equate United States feed consumption with the available supply could be calculated at once. This adjustment gave the equilibrium price in each region (assuming the specified arrangement) and the equilibrium rate of feed consumption.

A comparison of these regional feed consumption estimates with the given values of feed production yields the net imports or exports of each region. In conjunction with the assumed arrangement, the estimated quantity of feed shipped over each interregional path can be worked out. The arrangement is then tested for the equilibrium requirement that no trader can make a profit by shipping additional feed from one region to another. If this condition is met, the assumed arrangement is also the final one. If not, it is usually very easy (in a 10-region model) to modify the trading arrangement in such a way as to eliminate any remaining profit possibilities.

This approach was adapted to the present joint feed and livestock model as follows: (1) A separate equilibrium arrangement was determined for feed by assuming that the livestock numbers in Table I were given and that livestock prices in all regions were $16.80. The resulting arrangement is shown in Table VII. Then we determined a similar independent arrangement for livestock, assuming livestock numbers fixed. This arrangement is shown in Table VIII. These arrangements imply definite structures of regional price differentials for both feed and livestock.

As a next step, the livestock prices from Table VIII were substituted into the demand equations for feed, yielding a revised equilibrium solution for feed. This revised solution for feed, in conjunction with Table VIII, would represent the joint spatial equilibrium solution we are

TABLE VII — INDEPENDENT EQUILIBRIUM SOLUTION FOR FEED PRICES, CONSUMPTION, AND NET TRADE UNDER APPROXIMATE 1949–50 CONDITIONS[a]

Region	Differential from Corn Belt (1)	Equilibrium Price (2)	Feed Consumption (3)	Feed Production (4)	Net Trade (5)	Origins and Amounts of Net Imports: Corn Belt (6)	Northern Plains (7)	Moun-tain (8)	Total (9)

[a] Assumes livestock numbers fixed at levels shown in Table I.

Note: Figures may not check in the last decimal place because of rounding.

seeking *if livestock production in each region were predetermined.* But as livestock production is a jointly dependent variable in our model, we proceed to substitute the regional prices for feed and livestock into the regional supply functions for livestock. If the sum of the resulting regional livestock production estimates is not equal to 166.12, we make a "gross" adjustment as follows:

For the nation as a whole (assuming rigid price differentials) we transform equations (5.1), (5.3) and (5.4) respectively into

(6.1) $\Delta Z_h = 61.5271\ \Delta P_c - 7.6909\ \Delta P_h$ (demand for feed)
(6.2) $\Delta Q_h = -4.9441\ \Delta P_h$ (demand for livestock)
(6.3) $\Delta Z_h = -31.7600\ \Delta P_c + 3.9700\ \Delta P_h$ (supply of livestock),

where the Δ's represent changes in the variables from their initial values.[11]

As Z_h in equation (6.1) and Q_h in equation (6.2) were chosen equal in the independent livestock and feed solutions, any *changes* in these two variables to reach a final joint equilibrium must also be equal. This implies the relationship $\Delta P_h = 22.3996\ \Delta P_c$ (obtained by solving equations (6.1) and (6.2) under the condition that ΔZ_h equals ΔQ_h).

Suppose that, on substituting the initial sets of livestock and feed prices into the regional livestock supply functions, we find that the resulting estimate of total United States supply is equal to $Q_h - 2$. We shall call this supply estimate Z_h (3), to denote that it is associated with equation (6.3). Then, to reach equilibrium, Z_h (3) must increase and Q_h must decrease in such a way that ΔZ_h (3) $-\Delta Q_h = 2$. The extent of the change in each variable is easily calculated from the equations shown. The changes in Z_h (3) and Q_h imply that the price of feed in each region must change by a constant amount and that the price of livestock in each region must change by another constant amount. When these changes are made, the system is in "gross" equilibrium. If this step causes a change in the equilibrium trading arrangements for either feed or livestock, some further minor adjustments are needed to complete the joint equilibrium solution.

The joint equilibrium solution under approximate 1949-50 conditions is shown in Table IX. The trading arrangement for feed is simple and logical in most respects. The Corn Belt ships feed to four deficit regions, namely the Northeast, Southeast, Appalachian and Delta. Prices in these regions are equal to the Corn Belt price plus freight. The Lake Region supplies part of the feed requirements of the Northeast and its price is equal to the price in the Northeast region minus freight. The Northern Plains region ships feed to the Pacific and

[11] The transformation consists simply of solving each of the original equations for Z_h or Q_h and passing to first differences. The latter change eliminates all constant terms and those variables whose United States totals are predetermined, specifically Q_c and Y^*.

Pacific	1.4588	17.5983	16.93	6.70	−10.23		0.20	10.03	10.23
			166.28	166.28	0.00	30.18	5.72	12.41	48.31

[a] Under the assumed structure of freight rates, this amount of feed is shipped to the Corn Belt and reshipped to deficit regions in addition to the 9.52 million tons classified as *net* exports from the Corn Belt.

[b] Includes 2.13 million tons received from Northern Plains and reshipped to other regions.

[c] Excludes 2.13 million tons of imports into the Corn Belt offset by re-export.

Southern Plains regions, with the Mountain region serving as an auxiliary source of supply for the Pacific. The only additional item needed is a link connecting these two systems. In this case it turns out that the Corn Belt in equilibrium would import some feed from the Northern Plains and re-export an equivalent amount to other regions. Hence, the link is provided by the fact that the price in the Corn Belt is equal to that in the Northern Plains plus freight. The total net interregional trade, exclusive of re-exports, is 13.97 million tons, or about 12 per cent of the total feed concentrate supply.

The three major surplus regions with respect to feed also prove to be surplus with respect to livestock. The Northeast is by far the largest importer of grain-consuming livestock and the Pacific region ranks second. In equilibrium, the Corn Belt ships livestock to the Northeast, Appalachian, and Southeast regions. Prices in these regions are equal to the Corn Belt price plus freight. The Lake Region supplies the remaining requirements of the Northeast, but it also ships a small part of its export supplies to the Pacific region. Hence, the price of livestock in the Lake region is equal to the Northeast price minus freight, and the Pacific price is in turn equal to the Lake price plus freight. The Pacific region gets the great bulk of its livestock imports from the Northern Plains, so that the price in the latter region is equal to the Pacific price minus freight. In addition, the Northern Plains supplies the import requirements of the Southern Plains and Mountain regions so that their prices are equal to the Northern Plains plus freight. The Delta region proves in this model to be self-sufficient with respect to livestock.

Total net interregional shipments of livestock products are estimated as equivalent to 48.31 million grain-consuming animal units, or about 29 per cent of the total production of grain-consuming livestock and products.

Table X compares the net trade estimates obtained from the joint equilibrium model with estimates based on simpler "common sense" assumptions. Columns (1) and (2) compare the quantity of feed produced in each region with the quantity needed to feed its actual 1949-50 livestock numbers at the U.S. average rate. The feed surpluses and deficits implied by this comparison are shown in column (3) and the net imports and exports resulting from the joint equilibrium model are shown in column (4). The correspondence is obviously close.

Column (6) shows the regional distribution of livestock consumption if per capita rates in each region were the same as for the United States as a whole. Column (7) redistributes these regional livestock consumption estimates by adjusting them for regional differences in per capita disposable income. It is assumed, based on both time-series and family-

budget analyses, that a departure of 10 per cent from the national average in per capita disposable income will be associated with a departure of 4 per cent in per capita consumption of livestock products. Columns (8) and (9) show a close correspondence between the livestock net trade estimates obtained in this fashion and those obtained from the joint equilibrium model.

These comparisons do not prove that the model accurately portrays the interregional trade pattern of the real world (much of which is unknown due to inadequate data), but they at least suggest that the model and the manipulations applied to it involve no serious mechanical or arithmetical imperfections.

Equilibrium solutions were also calculated on the basis of various changes in the initial data. The results of two of these solutions will serve to illustrate the flexibility and usefulness of the model.

A. *Effects of a severe drought.* In one variation, feed supplies were assumed to decline about 30 per cent in the Corn Belt and 75 per cent in the Northern Plains. These drops were closely comparable with the actual changes from 1935 to 1936. Feed supplies in other regions were assumed to be unchanged.

In the equilibrium solution, the original trading arrangement for feed was drastically altered. The Southeast region became self-sufficient, neither importing nor exporting feed. The Northern Plains became a major feed-deficit area, drawing supplies from the Lake, Corn Belt, and Mountain regions. The Appalachian region shifted to a surplus status, shipping to the Northeast. The Southern Plains also moved to a surplus position, shipping a small quantity of feed to the Delta region. Feed prices in the Northern Plains rose 28 cents a bushel relative to prices in the Corn Belt; altogether, 7 of the 9 regional price differentials from the Corn Belt were changed by the drought situation. Net interregional trade in feed dropped more than 25 per cent.

The original trading arrangement for livestock was not changed by the assumed drought, although two regions narrowly missed shifting from a deficit to a self-sufficient status. The drought situation found the Appalachian and Mountain regions importing less than 1 per cent of their livestock requirements, compared with 5 or 6 per cent in the 1949-50 solution. The Delta region remained self-sufficient in the drought situation. but its livestock price declined relative to that in the Corn Belt. All other livestock price differentials remained as in the 1949-50 solution. Net interregional trade in livestock declined about 12 per cent, less than half as much as did interregional shipments of feed.

This type of solution should be helpful in appraising the incidence of future droughts upon livestock producers in different regions and in

TABLE X.—JOINT EQUILIBRIUM ESTIMATES OF NET TRADE IN LIVESTOCK AND FEED COMPARED WITH ESTIMATES BASED ON SIMPLER ASSUMPTIONS

[a] Assumes the U. S. average rate of feed consumption per animal unit in each region.
[b] Assumes the U. S. average rate of per capita consumption in each region.
[c] Assumes that a departure of 10 per cent from the national average level of disposable income is associated with a departure of 4 percent from the national average consumption of livestock products.

evaluating the benefits of feed grain storage programs. A related application involves estimating the pattern of feed prices and shipments likely to emerge at harvest time on the basis of advance forecasts of feed production in each region.[14]

B. *Effect of an increase in freight rates for feed.* An assumed increase of 50 per cent in all freight rates for feed changes the 1949-50 trading arrangement in only one respect—the Lake region shifts from a surplus to a self-sufficient status with respect to feed. However, substantial changes occur in feed price differentials and in the volume of interregional feed shipments.

The effects of the freight rate increase can be shown more clearly if we first assume that livestock numbers and prices in each region are held constant at their 1949-50 joint equilibrium levels. It is obvious that the change in freight rates will increase the feed price spreads between surplus and deficit regions. For example, feed prices in the Pacific region are increased about 11 cents a bushel and those in the Northern Plains are reduced about 9 cents a bushel. These price changes also have consequences for consumption and interregional trade. The Pacific region will consume less feed at the new higher price, and the Northern Plains will retain more feed at the new lower price. Thus, imports into each deficit region and exports from each surplus region are reduced by varying amounts. The over-all reduction in interregional trade in feed is about 8 per cent under the present assumptions.

When livestock prices and production are permitted to vary, however, further consequences become evident. Livestock production decreases slightly in the feed deficit regions and expands a little in the feed surplus regions. The regional adjustments in livestock production are such as to reduce interregional shipments of feed another 7 per cent. The final effect of the assumed increase in freight rates for feed is (in the present model) to reduce interregional feed shipments by nearly 15 per cent from the 1949-50 joint equilibrium level. Thus, the increase in freight revenues from feed is only 25 or 30 per cent rather than the 50 per cent which might have been anticipated in the absence of demand and supply adjustments.

III. *Applicability of Spatial Equilibrium Models to Other Commodities and Types of Market Structures*

Spatial equilibrium models have considerable appeal in that they include all of the elements—demand functions, supply functions, and transport costs—which are theoretically required for solving inter-

[14] Such forecasts or "early season indications" are published by the Department of Agriculture at monthly intervals during the growing season. A forecasting application of the independent feed model was presented in the earlier paper by Fox. (See footnote 2.)

regional pricing and trade problems at the industry level. It is our impression that many freight-rate problems are conceived in terms of rates to a given destination from two or three competing sources, and that indirect effects on the rest of the economy are disregarded. These effects may indeed be small in most cases, but they can only be checked by constructing a model which explicitly provides for their measurement. Similarly, we suspect that in estimating regional deficits or surpluses few marketing firms take explicit account of the slopes of regional demand curves.

For example, an assumption of equal per capita consumption in all regions would be appropriate (1) if transport costs were zero and (2) if all demand and supply functions were completely inelastic.[15] Hence, the gain in knowledge resulting from a more complete model increases with the importance of transportation costs (relative to commodity price) and with increasing elasticities of supply and demand.

The stability of trading patterns and price differentials for a given commodity from year to year depends on the above factors and also upon the degree of regional specialization—that is, upon the size of the net trade of each region relative to its total production or consumption of the commodity. It may be perfectly obvious that some regions will retain their surplus positions under almost any conceivable circumstances. But a region which imports less than 5 per cent of its requirements in normal years may well shift to a self-sufficient or even a surplus position on occasion, involving sharp price changes relative to other regions.

Spatial equilibrium models should be useful in understanding the price and trade pattern of any farm product or industrial raw material which is characterized by competitive markets and continuously varying prices. They are obviously applicable to international as well as to interregional market structures.[16] They can be extended to groups of three or more related products; the relationships may be either competitive or complementary in demand, supply, or both. (The livestock-feed model illustrates a derived demand or raw material and finished product relationship).

Some of the short cuts used in the livestock-feed model depended upon the assumed linearity of the demand and supply functions. How-

[15] Strictly speaking, the assumption that per capita income and other relevant variables are the same in all regions is also implicit.

[16] Some applications to international trade problems are given in K. A. Fox, "The Use of Economic Models in Appraising International Trade Policies," *Jour. Farm Econ.*, Dec 1954, XXXVI, 944-58. Effects of changes in tariffs, subsidies, import quotas and price-support programs are illustrated in terms of a model similar to that of Table VII.

ever, curvilinear functions should not greatly increase the difficulty of solution.[17]

The applicability of spatial equilibrium models to products with administered prices is less obvious. However, the aggregate demand curve for such a product in each region can be regarded as a continuous function. The marginal cost curve of each plant (or the industry marginal cost curve if there were several plants operating in a given region) could be either a continuous function or a series of steps. If there were only a few plants producing a given commodity, each plant might be treated as a surplus "region" with zero consumption and each consuming center might be treated as a deficit region with zero production. The maximization criterion could be varied according to the competitive structure of the industry. For example, if one firm held a nationwide monopoly but operated plants in several locations, it would be possible to calculate a price, output and shipment pattern which would maximize monopoly profit.[18] On the other hand, if each plant were owned by a different firm, a solution could be obtained under which each firm maximized its returns by equating marginal net revenue (f.o.b. plant) from all markets to which it could ship profitably. Appropriate maximization criteria could also be applied to an industry in which each of two or more firms operated plants at a number of locations.[19]

Thus, the chief limitation of the spatial equilibrium model with respect to administered-price commodities is that it does not accurately express the mechanism by which actual prices are determined. Nevertheless, given the necessary information about demand and cost curves, the spatial equilibrium model indicates an optimum price and trade pattern which could be a useful guide in setting administered prices. It can also indicate the pressures on an existing market pattern which would result from the construction of new plants at specified locations.

Conceptually, the spatial equilibrium model is one of very wide applicability. It is not excessively difficult to manipulate. The most serious

[17] Theoretically, some types of curves might lead to multiple solutions. But this is not likely to happen with functions of realistic shape, such as monotonically decreasing demand curves and horizontal, vertical, or monotonically increasing supply curves.

[18] This is not to suggest that firms do, should, or can maximize monopoly profit without regard to other considerations. Conceptually, any limitations on the pursuit of profit which were set by public authorities or by company policy could be incorporated into the model. The model could also be used to estimate the pattern which would result if the various units of such a firm were operated competitively.

[19] Maximization could be carried out subject to various policy constraints relating to price leadership, market shares, and so forth. Here again the spatial equilibrium model is both neutral and flexible

limitation upon its use is independent of the model as such, namely the difficulty of determining the individual demand and supply or cost functions. Statistical demand functions for many farm and food products have been determined with considerable reliability, and there is no conceptual barrier to their derivation for industrial products. In determining prices, large firms must now consider on a judgment basis information which is logically related, or even equivalent, to market demand functions. It seems reasonable to believe that the decisions of such a firm could be improved if these intuitive judgments about demand in various markets were formalized into demand functions and these in turn combined into a model of the entire market structure in which it was interested.

The success of operations-research groups in applying the "transportation" and "contract award" models to practical problems suggests that experiments with the spatial equilibrium model might be both instructive and profitable. The other two models deal only with limited aspects of a firm's activities or even with individual procurement operations. The spatial equilibrium model, on the other hand, can encompass broad economic characteristics of an industry which condition the success of major policy decisions by the firms within it or by public bodies whose regulatory activities impinge upon it.

SOVIET PRICE REDUCTIONS FOR CONSUMER GOODS, 1948-1954

By COLIN D. CAMPBELL AND ROSEMARY G. CAMPBELL*

The earliest reference to Soviet price reductions is a statement by Stalin in 1946 that "special attention will be devoted to expanding the production of consumers' goods, [and] to improving the living standards of the workers through consistent price reductions on all commodities."[1] Although the Soviet government raised prices of many consumer goods in 1946, and the fourth five-year plan directive, which was published a month after Stalin's statement, did not mention price reductions, the Soviet government has lowered the prices of a large number of consumer goods each spring from 1948 to 1954. The fifth five-year plan directive in 1952 prescribed that:

> Retail prices of consumers' goods should continue to be reduced steadily, bearing in mind that lowering the prices is the chief means of systematically raising the real wages of the workers and employees and increasing the incomes of the peasants.[2]

For the first time since 1948, price reductions were not announced in March or April 1955. This may represent a change in price policy; however, it could also be due to the fact that the 1951-55 goal for price reductions was reached during the first four years of the fifth five-year plan.

The decline in prices during the past seven years is strikingly different from the trend of prices in the USSR prior to the second world war. Many Western economists have believed that planned economies would be bothered by rising prices. Hoover writes:

> While the prevention or cure of unemployment and depression is quite simple in a Soviet type of economy, the danger of inflation is always more real. This flows out of the circumstance that, from the standpoint of national planning, global underemployment of resources is likely

* Colin D. Campbell is on the staff of the division of research and statistics of the Board of Governors of the Federal Reserve System. The views expressed in this article are the personal ones of the authors and in no way reflect the views of the Board. Rosemary G. Campbell was formerly instructor in economics at Iowa State College.

> to exist only if there is an underestimate of the potential volume of production. Planners can always think of useful and even grandiose ways in which to allocate limited national resources. Since people in general want their wages and salaries increased, as well as their leisure, while they are always anxious to have prices of goods and services lowered, as well as anxious that the deductions by the economic system in the form of taxes for all purposes should be as low as possible, it is usually more likely that economic planners will err in the direction of disbursing more income than the planned utilization of the national resources will warrant.[3]

Gerschenkron also has stated that the postwar deflation in the Soviet Union may not last. He writes:

> As was the case in the thirties, the Soviet government, faced with the necessity of maintaining labor incentives and unable to provide real increases in the population's purchasing power because of the high rate of nonconsumption, may be driven once more to provide the *semblance* of such increases in the form of inconvertible increases in money wages. It is just possible that the current year 1952 will form the dividing line between the years of past deflation and those of coming inflation.[4]

This paper gathers together information about the price reductions from translated articles appearing in *The Current Digest of the Soviet Press*. The articles in the Soviet press are interesting not only because they help to explain the price reductions, but also because they throw some light on the nature of the Soviet pricing system for consumer goods.

I. *The Factors Making Price Reductions Possible*

Soviet leaders claim that they have been able to reduce prices because of large increases in output and lower costs. The 1950 price reduction decree states:

> In connection with new successes in industrial and agricultural production during 1949 and with increased labor productivity and reduced production costs, the Soviet government and the Communist Party Central Committee deem it possible to carry out, as of March 1, 1950, a new, third, reduction of state retail prices on foodstuffs and manufactured consumers' goods.[5]

However, the annual price reductions cannot be explained solely by the

[5] "Price Cuts and the Gold Standard," *Curr. Dig. Sov. Press*, Apr. 15, 1950, II, 16.

rapid increase in the output of consumer goods. They have been possible in part because the government has at the same time stabilized money wages. Since the second world war, the government has not resumed its prewar policy of continuously raising money wages, and it has strictly controlled payroll allocations to industries. The expansion in total money income due to growth in the size and skill of the labor force has been small compared to the increase in the output of goods. The 1954 price reductions perhaps show that large annual price cuts depend on the successful stabilization of money incomes. That the 1954 reductions were the smallest of those that have been granted is probably due to the fact that in 1953 money incomes were raised by cutting in half the contributions to the state loan, reducing the agricultural tax, and raising procurement prices for agricultural produce.

Soviet monetary policy has probably been consistent with their deflationary price policy, although no direct information is available on the money supply during the past seven years.[6] Because of the dual marketing system, a successful policy of price reductions in the state stores would probably be impossible under inflationary monetary conditions. Although the bulk of retail sales are made by state and cooperative stores where prices are set or directly influenced by government decree, there are also some free markets where fresh foods—fruits, vegetables, meats, and dairy products—are sold at uncontrolled prices.[7] If the quantity of money had been rapidly expanding, the gap between the fixed state prices and the uncontrolled prices would have grown larger, shortages in the state stores would have become acute, and the illicit resale of state merchandise would have been extremely difficult to control.

The Soviet monetary reform in December 1947 contributed to the postwar deflation by preventing a rise in the rate of spending when rationing was removed. Prior to the reform the real purchasing power of the large cash holdings of the populace was not large because uncontrolled prices were very high and ration points were needed in addition to cash to purchase the lower priced goods in state stores. When rationing was removed and uncontrolled prices fell, the real value of the cash holdings of the populace would have risen sharply if the government had not reduced money balances.

[6] Budget surpluses have been large since the second world war. There were small budget surpluses during the 1930's, but there was a large increase in the money supply probably because of an expansion of bank credit. See F. D. Holzman, "The Soviet Budget, 1928-1952," *Nat. Tax Jour*, Sept. 1953, VI, 247, and A. Baykov, *The Development of the Soviet Economic System* (New York, 1948), p. 421.

[7] Janet Chapman has estimated that in 1948 the free markets handled approximately 15 per cent of total retail trade. See "Real Wages in the Soviet Union, 1928-1952," *Rev. Econ. Stat.*, May 1954, XXXVI, 135.

Soviet writers also state that the government has temporarily sacrificed budget revenues in order to reduce prices. If prices had not been cut, either turnover tax receipts or profits would have been larger.[8] The 1949 price reduction decree states:

> This first stage resulted in making goods sold in state retail trade cheaper by at least 57 billion rubles in the course of a year. This sum represents a pure loss to the state budget. The loss had to be covered, and was actually covered subsequently by the government, thanks to a growth in labor productivity, a rise in production of consumers' goods, and a reduction in production costs. It was, however, at the same time, a pure gain for the population.[9]

The relation of the annual price reductions to the budget was further taken into account in the 1953 and 1954 budget announcements. The Minister of Finance resorted to an extremely unusual accounting practice by including certain revenues and expenditures that might have been incurred if there had been no price reductions. An amount slightly smaller than the annual savings to the population from lower prices in the state stores was added to both revenues and expenditures.[10] The inclusion of these items in the budget announcements probably has little significance except as an attempt by the Soviet government to convince the populace that it is deeply interested in their welfare.

II. *Uses of the Price Reductions*

The annual price reductions have been fully exploited for propaganda purposes. One example of this is the Soviet claim that the decline in prices in the USSR shows the superiority of socialism over capitalism. The Soviet deflation from 1948 to 1954 contrasts sharply with the trend of prices during this period in many other countries. Even though inflation reveals nothing definite about real economic developments in capitalist countries, Soviet writers state that it reflects the increasing misery of the proletariat. They write:

> Whereas the Soviet Union is consistently following a policy of reducing prices and improving the material and cultural standards of the workers, in the capitalist countries the imperialists, embarking upon a wild arms race, are shifting the burden of ever-increasing military expenditure to the shoulders of the working people.

[8] For a discussion of whether price reductions ever result from the lowering of turnover taxes, see J. Robinson, "Theory and Practice of Planning," *Sov. Stud.*, July 1952, IV, 57, and M. Dobb, "A Note on Turnover Tax and Prices," *Sov. Stud.*, Jan. 1953, IV, 273-74.

[9] "Price Cuts," *Curr. Dig. Sov. Press*, Mar. 29, 1949, I, 43.

[10] For a discussion of this unusual change in the Soviet budget announcements, see A Nove, "Soviet Budgets after Stalin," *Rev. Econ. Stat.*, Nov. 1954, XXXVI, 423.

> Retail prices constantly rise in the capitalist world, public consumption is curtailed, and the impoverishment of the workers becomes catastrophically intensified.[11]

The Soviet government has used both percentage reductions in consumer prices and estimates in rubles of the annual savings to the population to show how the scale of living has risen. In the prewar period the Soviet leaders published data on increases in money wages for this purpose, but they did not give a cost-of-living or price index that would be needed to translate the money wage figures into real terms.

In 1954 the Minister of Finance announced that prices of consumer goods and foodstuffs were approximately 57 per cent below their level in 1947, the year before the first annual price cut.[12] The government has also estimated that the total reduction in prices for the four years from 1950 to 1954 was more than 25 per cent and was in four years slightly higher than the five-year goal of 23.5 per cent.[13] The return to prewar levels of production since the second world war has resulted in unusually large annual increases in the supply of consumer goods.[14] Because money wages have been relatively stable and shortages have probably not been made substantially larger by the price cuts, the percentage reductions in prices measure roughly the rise in real wages—particularly for urban workers who are significantly affected by prices in the trade network. It is interesting that Janet Chapman has estimated that from 1948 to 1952 real wages increased between 58 and 66 per cent, which is similar to the percentage reduction in prices announced in the Soviet press.[15]

The estimated annual savings to the population shown in Table I are usually announced at the same time the price cut decree is issued. These annual gains are believed to be the difference in the estimated annual retail sales at the old and the new prices. In 1948 the gain was based on the lowering of prices accompanying the monetary conversion in December 1947, the 1949 gain on the first two annual price reductions which were made in April 1948 and March 1949, and the gains for 1950 to 1954 on the price reductions announced in the spring of those years.

[14] For estimates of the large increases in the output per capita of many basic consumer goods from 1948 to 1952, see Chapman, *op. cit.*, p. 148

[15] *Ibid.*, p. 146. The variations in Janet Chapman's figures are dependent on (1) whether real wages are examined before or after taxes and bond purchases, and (2) whether 1928 or 1937 cost-of-living indexes are used.

TABLE I.—SAVINGS TO THE POPULATION FROM ANNUAL PRICE REDUCTIONS, 1948–1954[*]
(billions of rubles)

Year	In State Retail Trade	In Collective Farm Markets and Cooperative Trade	In State Retail Trade and Cooperative Trade[a]	In Collective Farm Markets	Total
1948	57	29			86
1949	48	23			71
1950	80	30			110
1951			27.5	7	34.5
1952			23	5	28
1953			46	7	53
1954			20	—[b]	20[c]

[a] Since 1951 the gains from trade in cooperative stores have been included with those from state retail trade rather than with those from the collective farm markets. The reason for this change is not known, but since cooperatives have had some degree of independence in setting prices, they have probably not fitted into either group perfectly. On the mechanism for determining prices charged by both consumer and industrial cooperatives, see N. Jasny, *The Soviet Price System* (Stanford, 1951), pp. 63–64

[b] No amount specified.

[c] In August 1954, the prices of many fresh foods were raised. To offset the loss to the population from these price increases, prices of several foodstuffs were reduced starting in October 1954. It is not known what effect these midyear changes in prices would have on the total gains originally predicted for 1954 See "Decree on Seasonal Prices for Vegetables and Fruit," *Curr. Dig. Sov. Press*, Sept. 29, 1954, VI, 3–4.

[*] Sources: "Price Cuts," *Curr. Dig. Sov. Press*, Mar. 29, 1949, I, 43–44, "Price Cuts and the Gold Standard," *Curr. Dig Sov. Press*, Apr 15, 1950, II, 16; "New Reduction of Retail Prices," *Curr. Dig. Sov. Press*, Apr. 14, 1951, III, 29, "Zverev's Report on the 1954 Budget," *Curr. Dig Sov. Press*, June 16, 1954, VI, 19, "Retail Price Cut Decree is Issued," *Curr. Dig Sov. Press*, Apr 25, 1953, V, 5

The magnitude of successive price reductions in state and cooperative stores is large when compared with recent annual goals for state and cooperative trade. Total gains for 1951 to 1954, inclusive, amount to 116.5 billion rubles, which is 42 per cent of the 1950 planned goal of 275 billion rubles for state and cooperative trade.

Except in 1954 lower food prices in the collective farm markets have been listed as one of the results of the decrees.[16] In 1954 very small gains from lower prices in the collective farm markets were expected because reductions in food prices in state stores were extremely small during that year. Even though the government does not directly control collective farm prices, Soviet leaders have stated that price reductions in state retail outlets will "cause an identical drop in prices on the collective farm and cooperative market."[17] Collective farm prices have

[16] This presumption has caused Baykov to question the claimed gains to the population from price reductions. See A. Baykov, "Internal Trade During the War and Its Post-War Development," *Bull. Sov. Econ Develop.*, Sept. 1950, Bull. 4, 8.

[17] "Price Cuts," *op cit.*, p. 43.

probably fallen since the second world war because of the rapid recovery in the output of farm products. However, because state prices are already much lower than collective farm prices and shortages prevail in state stores, the relationship between state and free prices is probably the opposite of that which the government claims. Under such conditions state price cuts would tend to cause collective farm prices to rise. Lower prices in state retail outlets would tend to increase the amount of purchasing power that is left over to be spent in the free markets. Also, because some persons will want to increase their purchases when state prices are lowered, more buyers will be shifted to the free markets.

The price reduction decrees are also part of the continuous drive to stimulate the populace to greater effort. The Minister of Trade recently stated:

> No proof is needed of the fact that our state's efforts to improve the material status of the working class and the collective farm peasantry are being repaid one hundredfold to the socialist society. Labor productivity is increasing, cost of production is dropping, and the quantity of goods produced is growing and their quality is improving.
>
> Only in a socialist country does the working class realize and actually perceive that the higher labor productivity and the lower production costs, the more commodities there are for the working class, the lower prices are and the better the working class lives.[18]

After the price reductions, unions are directed to "explain exhaustively the importance of the new decrees to workers" and to "develop extensive socialist competition for fulfillment and overfulfillment of state plans by all enterprises . . . . for increased labor productivity and high-grade production techniques."[19] At this time industrial plants customarily make pledges to fulfill or overfulfill their plans.

III. *Price Cuts for Individual Items*

It is not clear what determines which items will be cut in price and what the magnitude of the individual price cuts will be. Joan Robinson believes that the annual price cuts are simply a means of increasing the general purchasing power of the population so that they will be able to buy the increased output of consumer goods. She has stated that when Soviet planners change prices they do not attempt to reach equilibrium through price adjustments for individual items. She writes:

> In general it is considered wrong in principle to use price as a means

[18] "Speech by Dep. A. I. Mikoyan," *op. cit.*, p. 13.

[19] "On Tasks of Trade Unions in Connection with Announcement of Price Reductions," *Curr. Dig. Sov. Press*, Apr. 14, 1951, III, 31.

> of cutting demand to equality with supply in particular commodities. . . .
>
> The overall cut in prices is intended to reflect the overall fall in cost of a range of commodities rather than that of each item taken separately.[20]

It is not known how Mrs. Robinson would explain the variations in price cuts among the items listed in Table II. These variations could reflect changes in the market conditions of different commodities. Price reductions for agricultural commodities have been relatively large, perhaps because of a change in the terms of trade between agricultural products and manufactured consumer goods.

Dobb says that conditions of supply are taken into consideration in making price changes. He writes:

> It is hard to believe that the differences of price-cut have not been influenced, at least in part, by current differences in the supply position (price-cuts tending to be smaller in the case of things which were still in short supply).[21]

A recent Soviet article supports Dobb's point of view:

> The price of individual products . . . deviates from the value. The practice of price-fixing involves the most diverse ratios of retail prices and unit costs.
>
> It is perfectly clear that in determining prices the demand for various commodities cannot be disregarded. The Soviet state is doing everything necessary to fully satisfy the requirements of the population. But in the case of some items price must be used as an instrument to regulate consumption of these items until production reaches a point required for maximum satisfaction of the demand.
>
> Fixing prices of goods without relation to the demand for them leads to a decreased rate of turnover of the goods. In some instances the setting of low prices fosters speculation in goods.[22]

Mrs. Robinson is correct in stressing the insensitivity of Soviet prices to changes in conditions of demand and supply over short periods. Table II shows that prices of many consumer goods have not been changed as often as once a year. Some items have been cut only once in seven years. In one of his essays on socialist calculation, Hayek pointed out that when prices of consumer goods are fixed by the government, the problem of how often prices should be revised presents a dilemma: if prices are changed frequently, the administrative costs of

[20] Robinson, *op. cit.*, p 57.

[21] Dobb, *op. cit*, p 274.

[22] D. Krondrashev, "Price Fixing and Problems of Economic Planning," *Curr. Dig. Sov. Press*, June 6, 1953, V, 11.

changing prices will be high, but if prices are changed infrequently, the demand for many items will often be unequal to the supply.[23] Soviet planners have apparently chosen to avoid the high administrative costs of changing prices frequently and to accept conditions of market disequilibrium.

Prices of individual items have been set so low in most cases that the demand for them exceeds their supply, even though the output of consumer goods has been increasing rapidly and official rationing was given up in 1947. Although Lange thought that in a socialist system equilibrium prices that would avoid shortages and surpluses could be found by a process of trial and error, such a pricing system is not found in the USSR.[24] The Soviet press often mentions that items sell out rapidly when placed on sale in state stores. The following examples are typical:

> The board of the Central Union of Consumer Cooperatives is still permitting intolerable disruption of the supply of certain goods to the collective farm countryside. In many districts there are still total stoppages in the sale of such everyday articles as salt, kerosene, soap, matches, shag tobacco, etc.[25]

> Sales clerks in Kazan have to listen to customers' complaints that sometimes stores have no spring or summer clothing or footwear, no stock of athletic goods, etc. The editors of the newspaper . . . have received letters from collective farmers who are puzzled to find no pails, pans, washbasins and other domestic items on sale in the villages.[26]

> There is a great demand for children's ski suits with napping but they are placed on sale sporadically.

> Many parents wish to obtain baize shirts. They are cheap, have beautiful patterns and, what is most important, they are warm. However, these shirts appear rarely and in insignificant quantities.[27]

> In the summer of 1953 I tried to get a pair of women's dress shoes repaired. But the Kiev shops had no leather soles. "Sometimes we have them," said the shopkeepers, "but right now we don't. Come back in a week."[28]

Writing paper			10			10	10
Cigarettes	10		20	10		5–10	
Vodka	20	28	16.7	10		11	
Beer	20		30			15	
Axes, spades, scythes, and pitchforks				10		20	20
Gasoline				20		25	44.5
Mixed fodder		20	25	15	15	10	5[a]
Carts, wheels, and wagon supplies						10	
Tires and tubes for light autos and motorcycles						10	
Bicycles	20	20	20	10		10	
Lamps and metal lanterns						10	20
Building Materials							
Window glass			20	20		10	
Wallpaper			20	10		20	20
Paints			10–20			10	10[a]
Cement		30	20			25	20
Plywood							15
Linoleum						15	
Stove castings						10	

The continuous gap between state and free prices is additional evidence of shortages in the state outlets for foodstuffs. If official prices were set so that demand at these prices just balanced the supply in the state stores, prices in the collective farm markets would be equal to the official prices. Several newspaper correspondents have reported that state prices were much lower than free market prices.[29] In 1954, Clifton Daniel reported that prices in a farm market near Moscow were 5 times as high for cucumbers, 4 times as high for potatoes, 2½ times as high for apples, and the same for tomatoes as in state stores.[30] In addition, a recent Soviet article reveals that state prices are occasionally far below the less rigidly controlled prices charged by the the cooperatives. It gives as an example a bookcase priced at 579 rubles by the Furniture Industry Artel, but sold for 235 rubles in the state stores.[31]

The Soviet press occasionally mentions types of informal rationing—such as queues, illegal extra payments, or limits to the quantity sold to one person. Some type of formal or informal rationing is inevitable when prices are set below equilibrium levels. A recent letter to a Soviet newspaper states that people have to stand in line to buy an automobile in Moscow and describes the market for automobiles in the following way:

> Unfortunately my trip was fruitless. There were more people trying to buy automobiles in Moscow than there were cars in the stores.
>
> I must mention that certain shifty enterpreneurs offered to "help" me buy an automobile on condition that I pay 10,000 rubles more for a Pobeda than its price.[32]

Another article reveals that in the market for building materials there are restrictions on the amount sold per customer per day:

> Last year I laid the foundation for my house with great difficulty. This year I received a loan of 10,000 rubles for private construction. But for two months now my wife and I have gone to stores and lumberyards to buy cement, bricks, boards, lumber, and other materials. It was no use. . . . We were not able to get anything.
>
> The Ukraine Republic Ministry of Trade does not concern itself with such a category of customers as private builders. The only buyers recognized are those for whom norms of 20 kilograms of cement, one cubic meter of wood, etc., are set. In order to obtain enough materials to build a house I would have to go to the store 100 times for cement, ten

[32] "Concerning the Automobile Trade," *Curr. Dig. Sov. Press*, June 23, 1954, VI, 34.

times for roofing, 25 times for lumber, etc. But since these materials are seldom in the stores, one can imagine the private builders' position.[33]

An indication of the seriousness of the shortages is that twice during 1954 Soviet leaders have passed resolutions to alleviate them. At a meeting of the cooperative organizations in July, a decision was adopted to "eliminate the absolutely intolerable instances of interruptions in trade of goods in everyday demand. . . ."[34] An August decree establishing seasonal prices for farm produce attempted to "ensure greater uniformity in selling it during the course of the year."[35]

Soviet writers usually attribute market shortages to negligence of officials, "Bureaucratic methods in management of enterprises," lack of order in the distribution of goods, production of profitable items rather than those most desired by consumers, failure to follow regulations, or dishonesty. One of the rare admissions that shortages are related to the price reductions is contained in a recent speech by the Minister of Trade. However, he also repeated the belief that setting prices of consumer goods where demand is greater than supply has a stimulating effect on labor because shortages obviously show that supplies are not sufficient. Even before the second world war, Soviet writers defended the setting of prices below equilibrium levels in this way. The Minister of Trade said:

> The increased real wages of workers, the rise in the living standard of the rural population and the systematic reduction of prices have all occasioned a rise in demand for consumers' goods which has out-stripped production of certain items such as meat and animal fats. Some people even have the impression that there are fewer goods to be had now than there were several years ago.
>
> There is a simple way of giving the illusion that there are enough goods and that is not to cut prices further, i.e., to prevent any increase in the public's purchasing power, as is done in capitalist countries. Then everyone will think that there are enough goods—and there will be enough goods: surpluses may even accumulate. But this is a violation in principle of both Soviet policy and the fundamental interests of the people. . . . If we are to get the better of the goods shortage, there is only one correct way open to us—to speed up the rate of consumers' goods production. This is the way the Communist Party has chosen.[36]

[33] "Where Can a Private Builder Buy Building Materials?" *Curr. Dig. Sov. Press*, June 6, 1953, V, 39.

[36] "Election Campaign Speeches by Soviet Leaders—II," *Curr. Dig. Sov. Press*, Apr. 28, 1954, VI, 3.

Actually, it is doubtful whether a low-price policy involving market shortages will have the beneficial effect on labor productivity claimed by Soviet leaders. High prices would probably indicate the need for increasing output just as effectively as shortages. Also, the inconveniences resulting from market shortages make shopping difficult and discriminate against employed persons and especially working wives.

Although the 1954 decree establishing seasonal prices for potatoes, vegetables and fruit raised their prices, Soviet planners probably do not intend to adopt a policy of lessening market shortages by raising prices. The 1954 action followed the unusually large reduction of 50 per cent in the prices of these foodstuffs in 1953, and it is the only known decree in the past seven years that has raised the prices of consumer goods. After years of government prices set far below equilibrium levels, market shortages probably seem normal to Soviet price administrators, and the populace has become accustomed to them.

It is important that conditions of market disequilibrium have not existed in the collective farm markets. At the higher prices in these markets, foodstuffs are usually available and shopping is much easier than in state stores. By providing some markets where shortages do not exist, peasant markets may have contributed significantly to the workability of the Soviet distribution system. However, it is interesting that in spite of their usefulness, the peasant markets are expected to disappear as communism develops.

IV. *The Problem of Minimizing Inventories*

There is probably an important, but unpublicized, advantage in setting prices below equilibrium levels. Low prices avoid the possibility of surpluses and keep inventories and storage costs at a minimum. The Soviet government has admitted that it has inadequate storage facilities, and it has attempted to encourage collective farms and consumers to store more foodstuffs.[37] During the postwar period when output was expanding rapidly, prices would have had to be set especially low to avoid eventual surpluses before the next price cuts were decreed.

Although the Soviet pricing system results in very small inventories, Dobb believes that inventories are extremely important in the Soviet distribution system. He writes:

> There are two main ways in which short-period variations in the supply-demand position of particular commodities can be met. One (which our Western textbooks have prejudiced us to regard as the normal way) is to allow short-period prices to fluctuate in response to the current supply-

[37] See "Decree on Seasonal Prices," *op cit*, p. 3, and "Zverev on Financial Discipline and Control," *Curr. Dig. Sov. Press*, Aug 30, 1952, IV, 4.

> demand relationship; and to regard a high ratio of short-period price to cost (or to some "normal value") as a *prima facie* reason for increasing supply in the ensuing plan-periods. The other is to keep prices (with some exceptions) in some fairly constant relationship to cost (or to "normal value") and to allow short-period variations in the supply-demand situation to result in varying rates of running-down of stocks (or even shop-shortages and queues). In this case priority for increased output in the next plan-period will presumably be assigned (other things being equal) to those commodities which show the quickest running-down of stocks or the longest queues. . . . The latter is a quite reasonable course to pursue, although it is not without its inconveniences for the consumer. In a period of rapid general improvement in the supply-position, however, such inconveniences may be regarded as relatively unimportant, and at any rate transitory.[38]

The "short-run economic problem" with which Dobb is concerned arises because within short periods, consumption frequently has to be adjusted and goods must be distributed with reference to an existing supply.[39] In a free enterprise system prices adjust consumption to production in the short run by rising when goods become scarce compared to demand and falling when they become abundant. As Dobb points out, these adjustments might also be performed by various forms of nonprice rationing such as queues. However, Dobb's suggestion that Soviet planners may be attempting to balance supply and demand in the short run by changes in inventory levels is very questionable. At present, Soviet prices appear to be set so low that retail inventories of many commodities do not exist much of the time. In order to have large enough inventories on hand to take care of short-run market fluctuations, prices would have to be so high that some merchandise would remain in stock even after demand at the official price had been completely satisfied. Such a system of distribution would undoubtedly require much larger storage facilities for consumer goods than exist in the Soviet economy at the present time.

Although the Soviet economy has had few surpluses resulting from setting prices above equilibrium levels, supplies of substandard goods or goods in unusual sizes have accumulated when official prices for them were too high. Because factories may fulfill their quotas by cutting quality or reducing variations in styles and sizes, goods that are difficult to sell at official prices are occasionally produced.[40] In 1953 there were large bargain sales to clear inventories of items that were unsalable at

[38] Dobb, *op. cit.*, p. 273.

[39] For a description of this fundamental economic problem, see F. H. Knight, *The Economic Organization* (Chicago, 1933), pp. 12-13, 78-82.

[40] See "The Consumer—Improve the Quality and Variety of Light Industry Products," *Curr. Dig. Sov. Press*, Feb. 8, 1949, I, 46.

official prices. In a recent speech the Minister of Trade described surplus conditions of this type:

> Whereas at the beginning of 1953 the trade network had a tremendous quantity of goods above plan left on hand, including unsalable goods of outmoded styles and of poor quality, in the year just ended the merchandise stocks left unsold above the established quotas have mainly been liquidated, while the quantity of unsalable merchandise has been substantially reduced.
>
> On the whole, surpluses in the trade network are now generally at a normal level.[41]

V. *Concluding Remarks*

Price reductions are probably superior to increases in money wages as a method of expanding consumption in a planned economy. The Soviet policy of inflation prior to the second world war had many disadvantages. Gerschenkron writes:

> There is no doubt that, in the past, inflation interfered considerably with efficient planning processes. It rendered difficult the ascertainment of relations between planned and actual cost of production in industry, and thus deprived the planners of their most important instrument for checking whether or not resources had been utilized in accordance with the plan. Furthermore, inflation provided the managers of industrial enterprises with a strong temptation to hoard raw materials, thus causing mal-allocations of resources within the economy, and further accentuating its character as a deficit economy and the disabilities and inefficiencies that flowed therefrom.[42]

The price reduction decrees are intended to be general welfare measures. Of course, price reductions in themselves would not make the Soviet people better off. Only increased availability of goods would do this. Also, farmers, who still comprise more than half the total labor force, have benefited much less than city workers. Because peasants are somewhat self-sufficient, they have benefited very little from the large cuts in state prices of foodstuffs. In addition, although employees' money incomes are stabilized, peasants' incomes fluctuate not only because they share in the variable output of the cooperative farms, but also because they still obtain a significant portion of their income from sales of farm produce in the free markets. Because of the dependence of the peasants on free market prices, the policy of stabilizing money incomes of employees, which causes free market prices to fall as farm output increases, tends to lower farm incomes. On the other hand,

[41] "Speech by Dep. A. I. Mikoyan," *op. cit.*, p. 12

[42] Gerschenkron, *op. cit.*, pp. 30-31.

it is interesting that price reductions in state stores have probably tended to maintain peasant incomes because state price cuts tend to retard the decline of free market prices. In addition, perhaps to offset the unequal advantages to farm and city workers, in 1953-54 farm incomes were raised by special measures such as lowering compulsory delivery quotas, reducing agricultural taxes, and raising the procurement prices paid by the state for obligatory quotas.

INPUT-OUTPUT ANALYSIS AND ECONOMIC STRUCTURE

A Review Article

By LEONID HURWICZ*

It was only after having undertaken[1] the review of the present volume[2] that the writer became aware of the magnitude of the task, comparable to that of appraising, say, a year's contents of a thriving periodical. Even the book's length (541 pages, not counting indices and "fold-in" charts) fails to give adequate warning of its tremendous scope and wealth of material.

As indicated in the preface, the volume is a product of the first three years of the Harvard Economic Research Project set up with the help of a Rockefeller Foundation grant, partly financed by U. S. Air Forces funds, greatly helped by the cooperation of the Bureau of Labor Statistics, and, of course, founded on the earlier accomplishments of Leontief and his collaborators.

The first four of the volume's twelve chapters are by Leontief. The first three ("Introduction," "Structural Change," and "Dynamic Analysis") comprise Part I, entitled "Static and Dynamic Theory." The fourth ("Interregional Theory"), together with Walter Isard's paper ("Some Empirical Results and Problems of Regional Input-Output Analysis") constitute Part II. Part III consists of two papers dealing with capital structure: "The Structure of Capital" by Robert N. Grosse and "The Telephone Industry: A Study in Private Investment" by Paul G. Clark. Part IV, entitled "Explorations in the Use of Technological Data," contains "Process and Production Functions from Engineering Data" by Hollis B. Chenery, "Problems of Classification and Aggregation" by Mathilda Holzman, "The Technological Structure of the Cotton Textile Industry" by Anne P. Grosse, and "Commercial Air Transportation in the United States" by Allen R. Ferguson. Part V ("Consumption and Final Demand") consists of "The Role of Demand in the Economic Structure" by James S. Duesenberry and Helen Kistin.

A striking characteristic of the "product-mix" represented (in variable proportions!) in this volume is the interplay of empirical results, methodological discussion, and theoretical model construction. Thus Leontief's "Structural Change," located in a part "reserved" for theory, is largely devoted

* The author is professor of economics and mathematics at the University of Minnesota

[1] Following the untimely death of the previously designated, and much more suitable, reviewer—Professor A. Henderson of the Carnegie Institute of Technology. The present reviewer profited from reading Henderson's multigraphed paper, dated June 30, 1953, entitled "The State of Input-Output Analysis."

[2] Wassily Leontief, and others, *Studies in the Structure of the American Economy—Theoretical and Empirical Explorations in Input-Output Analysis* (New York: Oxford Univ. Press. 1953. Pp x, 561. $11.00). Referred to as *Studies* in this article.

to the presentation and analysis of the empirical data on input-output coefficients in 1919, 1929, and 1939; at the same time, the paper has a mathematical appendix containing the derivation of certain algebraic relations relevant in analyzing the phenomena of structural change. Similarly, papers by Clark, Chenery, Holzman, Duesenberry and Kistin (the listing is not meant to be exhaustive!) are of considerable interest not only as empirical monographic studies, but also as contributions to methodology and economic theory.

Among the empirical studies, as can be seen from the titles, some are focused on one sector of the economy defined in terms of a commodity or industry; others cut across the whole economy, though with emphasis on a specific aspect (structural change, interregional structure, capital structure). Theoretical models largely correspond to the empirical materials handled, although not necessarily with the same scope or emphasis. Thus Leontief's dynamic theory goes much beyond the empirical use made of the available time series, while the theoretical basis underlying the computation of the inventory coefficients is rather played down.

Methodological problems arising in the treatment and interpretation of empirical data are discussed in almost every paper of the *Studies*. Some (as in the paper by Duesenberry and Kistin) are essentially in the domain of the theory of statistical inference. Some (*e.g.*, Holzman) deal with statistical decisions (unrelated to sampling issues) such as those of aggregation. Others (*e.g.*, Chenery) are concerned with the fitting of theoretical analysis together with the available statistical materials. Leontief himself raises a host of fundamental questions concerning the role of theory and empirical analysis in economics.

The detailed appraisal of each of the contributions in the *Studies* would take the reviewer far beyond the limits of his competence. It seems, therefore, preferable to follow up some of the issues common to most of the papers in the volume and try to answer (or at least formulate) some of the questions that are likely to be asked by an economist. This selection, unfortunately, is unfair to some of the contributors; let it be emphasized that it reflects not the reviewer's value judgment but his limitations.

I. *The Basic Model*

Leontief's basic static model, well known from his earlier writings and conveniently summarized at the beginning of Chapter 2, consists of two sets of relations: the balance equations and the structural equations. Each balance equation states that the total output of a given industry is absorbed either by itself or by other industries, or by the "outside" sector (*e.g.*, consumption). If the number of industries (apart from the "outside" sector) is m, the *balance equation* for the ith industry may be symbolically written as

$$X_i = x_{i1} + x_{i2} + \ldots + x_{im} + y_i$$

where

X_i is the total output of the ith industry,

x_{ik} is the amount of product of the *i*th industry absorbed by the *k*th industry,

y_i is the amount of the product of the *i*th industry absorbed by the "outside" sector.

The listing of the amounts absorbed by the "outside" sector (y_1, y_2 . . . , y_m) is called the "bill of goods." The ratio of the amount of the *i*th industry's product absorbed by the *k*th industry to the output of the *k*th industry may be called the *i*th *technical coefficient* in the *k*th industry, and is denoted by a_{ik}. Thus, in terms of the notation just introduced, $a_{ik} = x_{ik}/X_k$; this relation, when solved for x_{ik} becomes

$$x_{ik} = a_{ik} \cdot X_k$$

and is called a *structural equation.*

In the present volume this scheme is extended to cover situations involving interregional ("intranational") and dynamic analysis.

For interregional purposes it is, in principle, sufficient to split each industry into as many regional subindustries as there are regions and then write out the balance and structural equations for each of the subindustries; a simplification results if the technical coefficients do not vary from region to region, and percentage distribution of each commodity's output among regions is given. (Some commodities are assumed only to travel within the region of production.)

For purposes of dynamic analysis, one takes into account the fact that some of the output of a given period goes into stocks (capital goods or inventories). The stocks are assumed parceled out among the *m* industries, although the possibility of the "outside" sector holding stocks is not ruled out. If S_{ik} denotes the stock of the *i*th commodity held by the *k*th industry and $\dot{S}_{ik}$ the increase[3] (positive, zero, or negative) in S_{ik} over the given period, the balance equation of the *i*th industry now becomes

$$X_i = x_{i1} + x_{i2} + \ldots + x_{im} + \dot{S}_{i1} + \dot{S}_{i2} + \ldots \dot{S}_{im} + y_i$$

which merely says that the output must be absorbed by some industry, either on current or capital account, or else be used by the "outside" sector.

The ratio of stock of the *i*th commodity used by the *k*th industry to the output of the *k*th industry may be called the *i*th *stock (capital) coefficient* in the *k*th industry, and is denoted by b_{ik}, so that $b_{ik} = S_{ik}/X_k$. The equivalent relation

$$S_{ik} = b_{ik} \cdot X_k$$

is referred to as a *structural stock-flow equation.*[4]

[3] More precisely, all entities are regarded as instantaneous rates. $\dot{S}_{ik}$ is then the time derivative of S_{ik}.

[4] If $\dot{X}_k$ denotes the (positive, zero, or negative) increase in output of the *k*th industry, the stock-flow equation (if regarded as invariant) implies the "pure acceleration" relation $\dot{S}_{ik} = b_{ik} \cdot \dot{X}_k$ Leontief's more sophisticated "multiphase" model, as well as the empirical work of R. N. Grosse and Clark, takes into account the irreversibility of the accumulation process. In Grosse's work $b_{ik} = S_{ik}/\overline{X}_k$ where $\overline{X}_k$ is the capacity (rather than current output) of the *k*th industry.

II. *The Constancy of the Structural Coefficients*

Ex post one can (in principle) always obtain the so-called *structural coefficients* (the a's and the b's) if the required data on output and stocks (the x_{ik} and the S_{ik}) are available.

That such knowledge is extremely useful, there is no doubt; Leontief and his collaborators would have deserved thanks from economists, theoretical and applied, if they had merely determined the historical values of these entities. But, as the term "structural" indicates, Leontief and his group think of the a's and b's as having a considerable amount of *invariance*. With some oversimplification, the nature of this invariance may be stated as follows: Suppose that the a's and the b's have been computed on the basis of a given year's data. Imagine now that the same year is to be "relived" by the nation, with a different bill of goods and a different set of outputs. Again, the a's and the b's are computed from the "relived" year's data. They would be the same as those originally obtained! Hence, in a static model, the output X_k and the interindustry flows x_{ik} can be obtained, given the bill of goods and the knowledge (based on, say, past observations) of the technical coefficients. Similarly, in a dynamic model, the time paths of stocks, outputs, and interindustry flows can be obtained, given the time paths of the bill-of-goods components together with the knowledge of the structural coefficients and of certain initial values. (The mathematical procedures involved in the solution are described in considerable detail in Chapter 3, but the situation would be further complicated by taking into account the fact that neither outputs nor stocks can be negative.)

The postulate of invariance of the structural coefficients does not mean that the a's and the b's must remain the same from year to year. Indeed, Chapter 2 is primarily devoted to a comparison of the values of the technical coefficients (a's) in 1919, 1929, and 1939, but these changes, called "structural," are interpreted in terms of technical progress and similar phenomena. Yet traditional economics does not require the hypothesis of technological change to account for the change of the input-output ratios! The usual classroom picture of a production function is not a straight line through the origin but a curve, often S-shaped, exhibiting in its various phases the phenomena of increasing, constant, as well as decreasing returns; the typical isoquant map allows for variations in the ratios of the different inputs to each other; similarly for joint outputs. Furthermore, the traditional theory of the firm depends on the nonlinearity phenomena.

Superficially, the situation is distressing. For it seems that there are two irreconcilable approaches in economics: one where everything is proportional and the coefficients fixed, the other where the absence of proportionality and coefficient fixity is the cornerstone of the theoretical structure. However, while it would be unrealistic to deny divergence of emphasis and specializing assumptions, one takes comfort in the fact that the developments of the last decade have resulted in a theoretical structure broad enough to accommodate both the traditional (curvilinear) and the fixed coefficient (linear homogeneous) models as special cases of a more general model, to be

here called the ***generalized activity model*** (which is an extension of "activity analysis" encompassing nonlinear, as well as linear, processes[5]). Among the situations covered by the generalized activity model are: the linear programming model (of which Leontief's input-output model may be considered a special case), and the traditional curvilinear model (as, say, in Allen or Hicks). The fundamental feature of the generalized activity model is that, unlike traditional economics, it goes beyond commodity amounts and looks at the processes (activities) which use up or produce these commodities. Given the levels (intensities) of all activities, the inputs and outputs are assumed to be uniquely determined, regardless of levels of the other activities. If one then assumes independence (additivity), the total net (positive, zero, or negative) output of a commodity is obtained by summing the outputs attributable to each of the activities. (If an activity level is zero, so is its output of every commodity.)[6]

Since the activity level determines both inputs and outputs, it can be eliminated to yield relationships between the inputs and the outputs. In linear programming it is assumed that every input and every output is proportional to the activity level, hence (for a given activity!) the input-output (as well as input-input and output-output) ratios are constant. But even in the linear programming models these ratios are different for different activities, hence may change from one period to another because of resource limitations, price considerations, etc. (In nonlinear models the ratios may, of course, change *within* a given activity.)

There are several indications that the contributors to the *Studies* do think of their models as embedded in such a generalized activity model. Leontief's remarks on pages 32-33 may be interpreted as describing "structural change" in terms of some activity levels going down to zero while others, previously zero, have become positive. Chenery's "process functions" are designed to describe the (not necessarily linear) relationships characterizing a single activity (process). Holzman's comments (pp. 343, 357-59) deal with nonlinearities and variations in the process-mix. Also, Leontief's more sophisticated dynamic model (pp 68ff) takes into account the variability of the

[5] Including the possibility of a continuum of processes

[6] Where the number of activities is finite (say q) the model may be stated as follows: Denote the level of the pth activity by w_p and the total net (positive, zero, or negative) output (due to all processes) of the ith commodity by v_i (The number of activities q may be larger than the number n of commodities The list of commodities includes labor.) The fundamental technological relation for the ith commodity states that $v_i = f_i(w_1, w_2, \ldots, w_q)$, *i.e.*, that the choice of levels for all the activities uniquely determines the output of each commodity (the f_i are single-valued functions). When additivity is postulated, the total output may be split into parts attributable to the separate activities so that $v_i = v_i^1 + v_i^2 \ldots + v_i^q$ where v_i^p denotes the output attributable to the pth activity; in turn, $v_i^p = f_i^p(w_p)$, with $f_i^p(0) = 0$. The linear programming model is then obtained by requiring that $f_i^p(w_p) \equiv c_i^p w_p$ (with c_i^p constant), *i.e.*, that the ratios of outputs to activity levels be independent of those levels. The basic Leontief (open) input-output model is then obtained by requiring that $q = n - 1$ which (within the linear programming model) may be justified on grounds of efficiency. The "traditional" curvilinear models are analogous; they may be regarded as postulating a continuum of activities and nonlinear process relations f_i^p

capital coefficients (the b's) depending on whether the output is rising or falling.

Yet a good deal of the exposition is based on the assumption of constancy of the structural coefficients. This does not matter when one is merely providing a historical description of a given year. But where policy recommendations or predictions are envisaged—and Leontief's section on "policy decisions and the open system" (pp. 65-68) shows this to be the case—the assumption that variations in the bill of goods (as distinct from technical progress, exhaustion of natural resources, changes in consumer tastes[7]) would leave the technical coefficients unchanged must be questioned.

The reviewer finds it genuinely difficult to determine in what spirit the assumption of coefficient constancy is being made.

Is it adopted primarily to simplify exposition and presentation of the data? This interpretation suggests itself very strongly in the light of remarks made (p. 94) in connection with a relation which is assumed to be one of proportionality although Leontief believes it to be linear nonhomogeneous (*i.e.*, nonproportional). The reason given for adopting the assumption under the circumstances is that "since . . . no reliable empirical measures . . . are yet available, no useful purpose can be served by incorporating them [*i.e.*, the nonproportionalities] in the present theoretical formulation." In effect Leontief seems to be saying the following: "In the xy plane I have one point through which my line (representing the relationship) must go; if I do not have another point, I might as well draw it through the origin, even though I know it probably, does not pass there." (Similarly, if only one point is given on a curve going through the origin, one might as well draw it as a straight line.) This may be quite acceptable as an expository device, but is obviously dangerous in situations where the policy (or predictive) implications would be different depending on whether a line through a given point does or does not go through the origin. In such a case, an arbitrary choice of the origin as the second point might create the incorrect impression that the available data are adequate for policy (or prediction) purposes.

There are, however, alternative interpretations of the constant coefficient assumption. Thus one might be quite willing to regard the assumption as a valid approximation for certain small displacements of the system. But what about the large displacements? Even if the linear programming model is assumed (so that the input-output ratios are constant for each activity), changes in the process-mix could be expected to bring about variations in the historically observed input-output ratios quite independently of technological progress. The "traditional" economist would naturally expect to observe these variations, especially if the price ratios (or the composition of the bill of goods) underwent a strong change. Yet it has been shown[8] that even with a

[7] See p. 20.

[8] See the following contributions in *Activity Analysis of Production and Allocation, Proceedings of a Conference*, edited by Tjalling C. Koopmans, Cowles Commission Monog No. 13 (New York, 1951): Ch 7, "Abstract of a Theorem Concerning the Substitutibility in Open Leontief Models," by Paul A. Samuelson; Ch. 8, "Alternative Proof of the Substitution Theorem for Leontief Models in the Case of Three Industries," by Tjalling C.

changing bill of goods all efficient production possibilities are characterized by the same input-output ratios, provided it is assumed that for the so-called basic activities constant returns prevail, there is no joint production, every activity requires the use of labor, and labor is the only primary input. While it is not difficult to construct examples involving the violation of these postulates, there may be important situations where the postulates are likely to be satisfied. Thus Leontief's empirical case is stronger than one might at first believe.

In any case there is little doubt that the constant-coefficient model is extremely convenient and should be used where applicable. On a priori grounds one would expect it to be close to reality in some situations,[9] wide off the mark in others. But if the data, embodying so much industry and ingenuity, are to be used for prediction or policy, the coefficient-constancy assumption must be examined in the light of the observed phenomena. Until this analysis has been carried out, those postulating constancy for purposes of prediction or policy rather than exposition are open to Leontief's criticism (Ch. 1) for letting the theory get too far ahead of the empirical knowledge.

III. *Technology versus Behavior*

In "traditional" economic models the knowledge of the bill of goods and of the technological relations does not suffice to predict the output levels of the different intermediate and primary commodities. To make such a prediction one must also know whether firms are maximizing profits (or following some other behavior principle) and, if so, what the price relationships are.

In a constant coefficient model, on the other hand, the bill of goods determines the output of each commodity in a unique fashion Thus the constant coefficient approach seems to free us of the need for studying the complex problems of the firms' behavior patterns and market relationships. In fact, Leontief's remarks (p. 15) about the nonexistence of a discipline of economic psychology make one feel that he might regard it as unsound to have the behavior patterns brought into the picture.

Yet it is not easy to keep them out of the picture, especially when dynamic phenomena are being analyzed. The "irreversibility" of the accumulation process is a case in point. As Leontief points out (pp. 68ff.), while expansion in output (with capacity already fully utilized) may call for a proportionate increase in fixed capital, a decline in output would not result in a proportionate reduction in machinery and equipment. But this is not a purely technological phenomenon: with sufficiently pessimistic expectations and favorable scrap prices it might indeed pay to dismantle the plant.[10]

Koopmans; Ch. 9, "Alternative Proof of the Substitution Theorem for Leontief Models in the General Case," by Kenneth J Arrow; Ch 10, "Some Properties of a Generalized Leontief Model," by Nicholas Georgescu-Roegen. A generalized formulation, based on less restrictive postulates, is possible.

[9] See R. N. Grosse, p. 186, where theoretical arguments in favor of the capital-coefficient constancy are given.

[10] In discussing the possible indeterminacies and contradictions of the "multiphase" dynamic model Leontief hints (p. 75) at the "deeper layers of structural relationships,"

Clark's analysis of the determinants of investment in the telephone industry starts with the "pure acceleration" (proportionality) model, but then introduces such behavioral elements as "spare capacity," "irreversibility," and expectations of output. He recognizes (p. 250) that his modified model (the "capital requirements theory") is implicitly based on the profit maximization principle, and compares his model with a more "conventional," although unnecessarily crude, profit maximization approach. The crucial difference between the capital requirements theory and the "conventional" model described by Clark is that the former makes investment decisions insensitive to price ratios in general and to interest rates in particular. (There might, of course, be indirect sensitivity, since output expectations are not unrelated to the general condition of the market.) If, as Clark argues, the historical experience of the Bell System does indicate such insensitivity, the explanation is probably to be sought in the discrete nature of the capital variables and the presence of "corner optima." Thus Clark's model could (as he realizes) be fitted into a more sophisticated "conventional" model. An investigation of the problem from this viewpoint might be helpful in determining the class of situations in which the price insensitivity phenomena are likely to be observed.

The problem of price effects is also briefly considered by R. N. Grosse in his study of the structure of capital. He cites (p. 186) the switch from steam to Diesel power as an exceptional case where prices (in this case the coal miners' wage rate) did alter the capital coefficients and goes on to say: "But it is our view that exceptional cases of that sort do not occur frequently enough to destroy the usefulness of the fixed capital coefficient concept." In the reviewer's opinion, the preceding statement should be regarded as an empirical conjecture to be subjected to the usual procedures of verification. In the absence of systematic data on the subject everyone is entitled to follow his own hunch. The contributors to the *Studies* seem inclined to favor the hypothesis of price insensitivity. The reviewer, perhaps unduly impressed by the thinking and what Friedman has called the "casual empiricism" of many generations of economists, would expect to find price sensitivity in many important areas of the economic process.

Even those favoring the fixed coefficient hypothesis for capital equipment might hesitate with regard to inventories. R. N. Grosse states (p. 188) that "speculation may play a significant role in determining actual holdings"; hence, "they have been adjusted where possible to eliminate stocks exceeding what might be called the normal inventory stocks." For an input, these "normal" stocks are those said to be "required" by the users of the commodity and are assumed proportional to the user's level of output. Again, one might

but it is not clear whether these would be of a behavioral nature. With reference to a centrally guided system (*loc. cit.*), he does envisage the possibility of applying "certain maximizing rules." Incidentally, one wonders whether the contradictions would not disappear if the "anonymous" differential relations postulated by Leontief were replaced by difference equations (with arbitrarily short lags where desirable), each equation describing the behavior of a well-defined type of economic unit at time t, given the state of other variables at time $t-\tau$, $\tau>0$, and subject to technological restrictions and accounting identities. (If the relation system were complete, in the sense that the behavior of every type of unit was specified, one would also expect to avoid indeterminacies.)

expect that considerations of profitability, safety, and convenience would lead away from the simple proportionality idea with regard to inventories, just as was the case with regard to capital equipment in Clark's study of the telephone industry, but additional empirical work is needed to clarify this issue.

It would be surprising if economic analysis could be carried on successfully in ignorance of the principles guiding human behavior in connection with the decisions affecting production, construction of capital equipment, and the size of inventories.

IV. *Statistical Methodology*

The postulate of coefficient constancy, together with the related de-emphasis of behavioral aspects of the economic process leads to an attitude toward statistical procedures that, on the surface at least, differ greatly from that of other econometricians.

With considerable oversimplification, the reviewer sees input-output analysis as the process of "fitting" a one-parameter curve (a straight line through the origin) to a one-dot scatter diagram. If the curve to be "fitted" had two or more unknown parameters, no unique fit would be possible; in the jargon of recent theory, the relations would not be "estimable." Thus the formulation of a model where each relation has only one unknown parameter may be viewed as corresponding to the a priori identifying restrictions of the simultaneous equation models. Whether these (constant coefficient) a priori assumptions underlying Leontief's analysis are better founded or more realistic than those used in, say, Klein's models of the United States economy has not been established.

Now if a worker is unwilling to adopt the Leontief brand of simplifying restrictions, while still faced with one observation per (disaggregated) relation, he is forced to choose between a disaggregated but nonestimable model and one of the following two alternatives: a model which is made estimable at the (admittedly very serious) cost of considerable aggregation of variables, or any device which will yield more than one observation per relation. On the technological side, experimentation is, of course, the ideal answer and the volume's advocacy of engineering data is highly appropriate.[11] But where behavioral aspects of the structure are to be studied, experimentation is usually (though not always) ruled out and one is forced to resort to the examination of the history and time patterns of the relevant variables. Examples of this are to be found in Clark's (informal) test of the null hypothesis that prices and interest rates do not influence investment decisions, as well as in the Duesenberry-Kistin investigation of the demand function for certain consumer goods. Indeed how could one appraise the effects of price variations except by comparing different situations (not always obtainable at any one time point) in which different prices prevailed? The reviewer finds it, therefore, difficult to agree with the implications of Leontief's highly picturesque diagnosis (p. 7): ". . . in their desperate search for sufficiently large 'samples,' the

[11] Interestingly enough, when these data are used as is the case in the papers by Chenery and Anne P. Grosse (*cf* pp. 373-74), the emphasis on constant proportions largely disappears

proponents of indirect statistical inference found themselves driven toward the treacherous shoals of time-series analysis." The analysis of time series does indeed present special and serious difficulties, but these cannot be avoided except at the cost of neglecting the study of behavioral aspects of the economic structure and even certain purely technological phenomena.

Similarly, except for classroom purposes, the use of models more highly aggregated than those dealt with in the *Studies* is not a matter of a methodological predilection (as seems to be surmised by Leontief on page 6), but rather an unavoidable choice dictated in certain situations by the limitations of the data available (including even the highly disaggregated input-output figures) in relation to the number of parameters to be estimated.

Most workers in this field could probably agree on the ideal of having data which are highly disaggregated (as to commodities and processes), split by decision units ("cross-section"), and available for a sizable time period. But in the meantime one is forced to use data deficient in at least some of these respects. Economics is too poor to be able to discard any source of information, be it aggregated time series or disaggregated one-time-point observations, despite their admitted weaknesss.

One natural consequence of the use of one-observation samples is that sampling variation and error cannot be estimated. Hence the emphasis (and impressive sophistication) with regard to possible biases due to alternative classification and disaggregation methods (*e.g.*, Holzman), but little about the probabilistic aspects of the problem. An outstanding exception is, however, found in the Duesenberry-Kistin study[12] of demand for consumer goods. Here the non-observable stochastic component is explicitly introduced into the demand relations and the problems of bias due to possible correlation between the disturbance and the "independent" variables, as well as that of error in the "independent" variables, are openly faced. The issue is, of course, identical with that of the "single equation approach" bias discussed in the literature of the simultaneous systems. (It should be made clear that many other sources of estimation bias are also considered.) The demand study shows remarkable ingenuity in eliminating some of the sources of variation and the utilization of available data. Its findings (that demand elasticity for food is higher than estimated by Girshick and Haavelmo and that the hypothesis of "mysterious and arbitrary changes in taste" is not needed to explain the observations) are interesting and very important. Yet the authors are afraid (p. 477) that "it may be said that what we have done is to find the errors and then explain them away by postulating shifts in demand," though they defend themselves against such a charge. In the reviewer's opinion, there is only one way of avoiding this type of difficulty. Regardless of the path of discovery, the final results must be presented in the following conditional form: "If one adopts the class of a priori admissible hypotheses[13] (here the underlying assumptions are completely specified), the following are the (best unbiased, maximum likelihood, or whatever is applicable) estimates of (say) the elasticity coefficients based on

[12] Which is not of the one-observation type.

[13] *I.e.*, the statistician's large omega, representing assumptions which, in a given context, are regarded as firmly accepted rather than subject to testing

such and such data." The validity of such a statement is independent of the authors' state of mind and may be accepted or rejected by readers depending on their attitude toward the specification, estimation principle, or the reliability of the data.

The type of analysis represented by the *Studies* is of tremendous value and importance to the development of the science of economics and it is only natural that there should be controversy concerning certain aspects of its methodology and the domain of its applicability. It is important that this work be continued and that its relationship to other streams of thought in contemporary economics and econometrics be intensively explored. In the reviewer's opinion, such an exploration will typically reveal complementarity rather than substitutability.

LÖSCH ON LOCATION

A Review Article

By STEFAN VALAVANIS*

The Economics of Location[1] belongs to that class of works, of which each generation produces very few, that both introduce a new subject and exhaust it. As with the *Theory of Games*, or Keynes' *General Theory*, the main ideas are few and appear utterly simple once popularized. They are *fortunate* ideas; that is, they have many consequences that matter and that are not obvious.

My task is to sift and present simply Lösch's key ideas and results, to point out which of them have and which have not analogues elsewhere in economics, and to show which areas of economics are affected by his contribution.

Even if the earth's surface were perfectly homogeneous, it would become differentiated into farms, cities and roads for purely economic reasons. Economic activities would arrange themselves into honeycombs of regular hexagons. Regions would emerge with characteristic prices and wages, and would trade their characteristic products.

The purely economic reasons for spatial differentiation in the absence of historical or geographical accidents are three: economies of scale, transport costs and agriculture's need for space. With economies of scale and no transport costs whatever, all production would be concentrated in one, or a few, optimum-sized plants located at random. With transport costs and no economies of scale, a little of every product would be produced on every square inch of the earth's surface. With both economies of scale and transport costs, the result is intermediate: several production sites at definite distances compromise between mass production and freight costs. This is what happens if space as such is not an ingredient of production, as is approximately true in industry. In agriculture, however, acreage itself is an input. This fact alone, if there were no economies of scale or transport costs, would squeeze non-agricultural production into small sites.

Unquestionably, spatial differentiation will develop. What will it look like?

Price funnels and demand cones. Let population be equally dense everywhere and let all people have like tastes. If d, in Figure 1, is an individual demand curve for beer, and OP is the price at the brewery, which is at P,

* The author, recently with the Dominion Bureau of Statistics, Ottawa, is now assistant professor of economics at Northwestern University.

[1] August Lösch, *The Economics of Location*, translated from the second revised edition by William H. Woglom with the assistance of Wolfgang F. Stolper (New Haven: Yale University Press, 1954). The German title is *Die räumliche Ordnung der Wirtschaft; eine Untersuchung über Standort, Wirtschaftsgebiete und internationalen Handel* (Jena: Fischer, 1943). The Yale University Press has kindly given permission for the reproduction of Figures 20 (p. 106), 26 (p. 117), 28 and 29 (p. 125), and Table 7 (p. 119) in the book, which here appear as Figures 1, 5, 7 and 8, and Table I. Figure 2 is adapted from Figure 21 (p. 106) in the book

those living there will buy *PQ* bottles of beer. Farther away the price is higher by the amount of the freight, and the quantity demanded consequently smaller. At *F* no beer can be sold at all. Total sales are equal to the volume of the cone produced by rotating triangle *PQF* (Figure 1) around *PQ*. The brewery is surrounded by a *demand cone* (Figure 2) and by a *price funnel* (Figure 3) which is steeper the higher the freight per mile. The brewery's *sales area* is a circle of radius ρ. Likewise, its *supply areas* of barley, hops, and labor are circles of various sizes around *P*.

As long as profits are made, new breweries are established. Competition squeezes together the round sales areas into equal regular hexagons until both brewery profits and beerless areas have disappeared. Of all regular patterns
FIG. 1 DEMAND FIG. 2 DEMAND CONE

that can fill up the space, the honeycomb of hexagons minimizes total transport costs. This is true for every commodity. On the other hand, the size of the hexagons depends solely on the individual demand for beer, and on freights for beer and its raw materials.

This proves too much. If the criterion is minimum transport costs, why are they not eliminated altogether by people living right at the breweries? It is true that the optimum distance between breweries may not be optimum for bakeries or laundries, so that some transport costs would persist. However a best average distance could be found and people would group together in equally spaced identical settlements, each having a brewery, bakery and laundry.

Duality between agriculture and industry. Now we appreciate the full force of Lösch's distinction between agriculture and industry. Agricultural production is areal, industrial production is punctiform. The best location for the consumption of industrial goods is the city, whereas the best one for consumption of food implies an even distribution of the people. As long as products of the soil are an important item of demand, population will be scattered, if not continuously at least evenly, like polka dots, over the land.

Punctiform industry selling to areally spaced customers is characterized by *price funnels*. Conversely, areal agriculture selling to a punctiform city

is characterized by *crop gradients*—the continuous counterpart of Thünen's rings. This easy result, based on the duality between agriculture and industry, illustrates again Lösch's Midas touch.

Discontinuous settlement. There are two reasons why population should be scattered like sparse polka dots: (1) It is the best compromise between proximity to food and proximity to industrial production. (2) It is best for certain aspects of agricultural production. Shelter for cattle, the farm house,
FIG. 3 PRICE FUNNEL

the well, are not areal but punctiform, and some farm operations resemble those of the brewery. Hexagonal farms are best.[2] Farm houses will then be laid out on a 60-degree lattice (Figure 4).

Market sizes. Discontinuous settlement restricts the possible market sizes. If I publish a rural newspaper, I do not care how far from the printer's is the nearest or the remotest corner of my subscribers' farms, because the newsboy has to deliver to the house.[3] If a circulation of 7 copies is economical each newspaper serves an area like Figure 5. If a circulation of 9 is indispensable, my sales area (Figure 6) will include the seven original customers at N, H_1 to H_6 plus one-third of the six farms J_1 to J_6 of the next ring. The other two-thirds read rival newspapers like N_1. Circulation of 7½, 8, or 8½ and a hexagon intermediate between Figure 5 and Figure 6 is impossible, not because of discontinuity in the number of copies that can be produced, but because of discontinuity in the number of customers that can be found for them.[4]

Now a few definitions, yielding a jackpot of results:

n the number of *equivalent customers.* If a customer, like J_3, is on a boundary, he is divided up equally by the number of suppliers on whose areas he verges. In Figure 6, each J-customer is divided by 3. The J's then add up to 2 equivalent customers for supplier N, who has altogether 9 equivalent customers.

[2] Lösch's treatment here is incomplete. See page 115, note 12

[3] Or the mailbox, which is also on a 60-degree lattice of mailboxes

[4] Lösch does not notice that the tendency toward discontinuity of area sizes is helped from the input side A brewery gets its barley and hops from barns at H_1, . . . H_6 and not from all over the farm. Barley grown at A (Figure 6) goes to N_2, while barley grown at B (which is farther than A) goes to N.
FIG. 4 SIXTY-DEGREE LATTICE

b the distance between towns that produce rival products.
a the distance between original settlements.

Results:

(1) $b = a\sqrt{n}$; that is, the distance between two like enterprises is proportional to the square root of the number of equivalent customers.

(2) The size of a market area is always $a^2 n \sqrt{3}/2$.

(3) The number of equivalent customers increases by jumps according to the law

$$(3.1) \quad n = (k\sqrt{3})^2 + j^2$$

$$(3.2) \quad n = [(k + \tfrac{1}{2})\sqrt{3})]^2 + (j + \tfrac{1}{2})^2$$

where j runs the integers from 0 to k first according to (3.1) and then according to (3.2), and where k runs the integers from 1 to infinity. Thus the seventeen smallest market areas have 3, 4, 7,
FIG. 5 MARKET AREA $n = 7$

TABLE I.—THE FIFTEEN SMALLEST MARKET SIZES

Area No.	n	Area No.	n
1	$(1\sqrt{3})^2+0^2=3$	3	$(1\frac{1}{2}\sqrt{3})^2+(\frac{1}{2})^2=7$
2	$(1\sqrt{3})^2+1^2=4$	4	$(1\frac{1}{2}\sqrt{3})^2+(1\frac{1}{2})^2=9$
5	$(2\sqrt{3})^2+0^2=12$	8	$(2\frac{1}{2}\sqrt{3})^2+(\frac{1}{2})^2=19$
6	$(2\sqrt{3})^2+1^2=13$	9	$(2\frac{1}{2}\sqrt{3})^2+(1\frac{1}{2})^2=21$
7	$(2\sqrt{3})^2+2^2=16$	10	$(2\frac{1}{2}\sqrt{3})^2+(2\frac{1}{2})^2=25$
11	$(3\sqrt{3})^2+0^2=27$	15	$(3\frac{1}{2}\sqrt{3})^2+(\frac{1}{2})^2=37$

9, 12, 13, 16, 19, 21, 25, 27, 28, 31, 36, 37, 39, and 43 equivalent customers. (See Table I.)

Systems of networks. With uniformly distributed population (continuous or not) each industry has its characteristic size of hexagon and divides space with a honeycomb of such hexagons. Now if two or more honeycomb-shaped nets are thrown on a table at random, thread-density is neither uniform nor random. There are local bunchings of thread, and because of the regularity of the several nets, equally complex bunchings form logical patterns on the table. The same is true of the hexagons' centers. They bunch into regular patterns. Now and then in a small neighborhood we find both a brewery and a bakery, or both a bakery and a laundry. More rarely a neighborhood con-
FIG. 6 MARKET AREA WITH $n = 9$ EQUIVALENT CUSTOMERS

tains all three industries. Industrial centers, in other words, emerge in spite of continuous and uniform population.

Now suppose that hexagon nets randomly thrown together are no longer of continuously varying diameters, but come in a few assorted sizes. Bunchings and patterns of bunchings become more likely, because now the few assorted diameters have lowest common multiples, which was not true before. When farm houses are laid out as in Figure 4, the tendency for industrial concentration, low prices, high wages, and much commuting is intensified.

Urban cogwheels. We now lay honeycomb nets of the possible sizes together so that they have at least one point, the metropolis, in common (Figure 7). We rotate the nets so as to get a cogwheel pattern of six sectors with few and six with many production sites (Figure 8). With this arrangement (1) the
FIG 7 SYSTEM OF NETWORKS FIG. 8 COGWHEEL
greatest number of locations coincide, and a maximum of purchases can be made locally, (2) sums of minimum distances between industrial locations are least, and consequently shipments, transport costs and highways are minimized, (3) a very deep price funnel around the metropolis is surrounded by a ring of quite deep funnels around regional centers, and in between are rings of rings of less deep funnels.

These results have two very important consequences for traditional theory.[5] First, it is clear that the notion of an economic region is derivable and not primary. International trade theory can now explain rather than assume local cost differences on a homogeneous globe. Second, price funnels break up the landscape so completely as to make meaningless the concept of local price levels; no simple deductions can be made therefore about comparative advantage, migration of factors, or purchasing power parity.

Interregional equilibrium. When uniform natural endowments are assumed,

[5] Strangely enough, nothing in economic history or economic geography is invalidated This is because Lösch's main results have abstracted completely from historical and geographical accidents.

men, goods, and places are mutually determined. Every worker carries with him his individual demands. Every good requires certain inputs and a market area of a certain size. Every location, by its prices and rents, attracts or repels industries and dictates to men how they will spend their incomes.

Other things being equal, the following questions can be answered, one at a time, by means of marginal analysis: (1) What does a given person produce? (2) Who works at the production of a given good? (3) Where does a given person reside? (4) Who lives in a certain locality? (5) What does a given locality produce? (6) Where is a given good produced? That all six answers can be determined simultaneously is no surprise to the economist. Demands, freight costs, balance equations and marginal conditions are just enough to determine a solution.

How is this equilibrium restored if disturbed? In the short run, prices change and goods are transferred. Long-run disturbances lead to change of jobs or migration of industries. In fact all six relations play a part according to their price, time and space elasticities.

Price waves. Lösch devotes much space[6] to short-run disturbances and the transfer problem. I summarize this here only to present one last main idea, that of price waves.

Suppose a foreign firm suddenly orders from Paris 1,000 marks' worth of shoes instead of buying them, as it had formerly, in Berlin. In Paris, the price of shoes will rise; their market area will shrink but hides and nails will have to be bought farther afield. Workers will be attracted from other industries, and rents will rise. Neighboring shoe factories faced with shortage of materials and labor will raise the price of their shoes and bid up hides in their own supply areas. Paris will become the focus of inflationary price waves that ever expand in area, but ever diminish in intensity. This is so because the impact is divided among more and more establishments and other kinds of goods. Berlin would be the focus of deflationary waves.

Waves diminish because they divide. Their total volume, however, remains constant, unless, sooner or later, *compensatory absorption* occurs. To illustrate, Luxembourg with its new income may want to buy precisely what Leipzig had to give up.[7] This will wipe out the wave, not just divide and divert it. Compensatory transfer of goods may occur anywhere, in the Saar, on the Rhine, or in Mongolia. It does not have to take place on the Franco-German border.

Lösch's analysis uses tools of traditional economics, like maximization, pure competition, partial equilibrium, and simultaneous equilibrium. Conceptual analogies are less obvious.

The downward sloping demand of Figure 1 is analogous to that of imperfect competition. Localization of production corresponds to product differentiation. Space is to agriculture as time is to capital theory, an essential new ingredient.

[6] Pages 265-304.

[7] Compensatory absorption may occur on the major arc of the great circle through Paris and Berlin, say with Bordeaux absorbing what Königsberg had to give up, or it may occur off the great circle entirely.

As the Walrasian system determines relative and not absolute prices, so in Lösch the metropolis itself can be anywhere. The flattening of price waves is deceptively like the dying out of the multiplier. Compensatory transfer is a little like the Pigou effect.

Ideas with no analogues in ordinary economics, like the discontinuity of hexagon sizes (Table I), and the rotation of hexagonal networks (Figure 8) I find very rare. The persistence of rent differences in spite of homogeneous endowments is *not* due to any novel assumption.

That familiar concepts should generate startling results more than any other thing attests to the genius of August Lösch.

COMMUNICATIONS

On Underwriting Consumption and Employment

The purpose of this note is to amplify one aspect of my earlier proposal for underwriting full employment in the United States[1]—the part having to do with techniques for boosting consumption when it would otherwise fall short of the target. It is probable that the subject of full employment will claim the spotlight again when and if the world situation permits major reductions in armament expenditures, and it is at least possible that a policy of assured full employment in this country, if we had such a policy now, would help to hasten that day.

The question of feasibility depends, I have argued, on whether or not aggregate consumer spending is underwritten in addition to aggregate employment as such. Without that feature, a policy of guaranteed full employment could involve the government is so large a degree of direct responsibility for the creation of jobs—such as expansion of public works, and perhaps wholesale subsidies to, and/or control over, private production—as to compromise the essentials of our private-enterprise system. Because of that risk, such a policy (as contrasted with contracyclical policy in a more limited sense) is not likely to be voted in the United States in the foreseeable future. That risk disappears if aggregate consumer spending, too, is underwritten and maintained at a proper level, one high enough to keep reliance on supplementary public works within reasonable bounds.[2] The risk of an unbalanced

[1] See my "The Underwriting Approach to Full Employment: A Further Explanation," *Rev. Econ. Stat.*, Aug. 1949, XXXI, 182-92. Also my "The Underwriting of Aggregate Consumer Spending as a Pillar of Full-Employment Policy," *Am. Econ. Rev.*, Mar. 1944, XXXIV, 21-55; other papers collected in *Full Employment and Free Enterprise* (Washington, 1947); and "Employment the Key," *Christian Science Monitor*, July 23, 1949, mag. sec., pp. 2, 12.

[2] See "The Underwriting Approach . . . ," *op. cit.*, pp. 184-85, for my theory of the "correct" level of aggregate consumer spending. Briefly, (1), estimated full-employment GNP, minus (2), the sum of (2a) expected government purchases of goods and services, including all public works approved "for their own sake," (2b) expected gross private domestic investment (probably, as a general rule, the anticipated cyclical-average level), and (2c) expected net foreign investment, equals (3) the level at which personal consumption expenditures should be underwritten. Thus one may advocate, as I personally do, rather generous regular appropriations for public works, but the amount included in (2a), and hence reflected in (3), depends on the will of Congress. A foreign-trade balance, plus or minus, similarly affects, and is accommodated in, (3) because it registers in (2c) and, where due to foreign aid, etc., in (2a). Actually my proposal calls for setting, not a single target figure for aggregate personal consumption, but a range between a guaranteed floor and a guaranteed ceiling, the leeway allowed being possibly of the order of 2 per cent. A summary statement on how minimum and maximum levels both of aggregate consumption and of aggregate employment would be likely to be established and administered in practice, *i.e.*, the respective roles of Congress and the Executive and the requisite amendments to the Employment Act of 1946, appears in "Employment the Key," *op. cit.*; see also *Full Employment and Free Enterprise, op. cit.*, pp. 163-70.

budget remains, but this—a corollary of the danger of oversaving itself—is not, as the other risk is, one that our system of private enterprise cannot bear.

I have elsewhere suggested a number of alternative procedures for enlarging consumers' incomes directly when personal consumption expenditures would otherwise—even at a full-employment level of income payments—fall below the underwritten level.[3] For some time I was inclined to stress tax reductions or offsets. Here I wish to bring into consideration a different method, involving the use of what might be called Consumer Sales Premiums (CSP for short). This method would provide not only additional purchasing power but an actual inducement to spend. Where an income-tax rebate, for example, would not favor consumer spending relative to consumer saving, but rather would tend to raise the level of both, CSP would be distributed only in connection with consumer spending as such and hence would establish a direct incentive to spend more, both out of normal income and out of the premiums when cashed. Thus the target level of consumer spending would be reached at smaller cost to the government.

Certain other general characteristics of the CSP method may also be briefly noted here. It would not noticeably reduce anyone's incentive to work—a charge sometimes loosely leveled against consumer transfer payment schemes in general but actually valid in special cases only. It would be perfectly flexible as to the amount of "lift" to consumer income it could provide. And it would be reversible into a special sales tax,[4] with a minimum of difficulty or misunderstanding, in the event the problem shifted to one of avoiding an inflationary rise of consumer spending above its guaranteed ceiling.

CSP would take the form of small coupons or stamps, in convenient denominations, which would be used as follows: (1) The Treasury would distribute them to banks and designated post offices throughout the country. (2) Banks and post offices would pass them along, when authorized by the responsible agency in Washington, to "retailers"—stores, service establishments, independent professional practitioners such as doctors—in ratio to their certified

[3] See "The Underwriting Approach . . . ," *op. cit.*, pp 187-88 It is important to note that such measures—indeed, all *compensatory* measures under this plan, whether they be (a) such measures, taken in relation to current rates of consumer spending, to expand or contract consumer income directly, or (b) measures, taken in relation to current levels of employment, to expand or contract public works (and, incidentally, hold income payments at the full-employment level)—are viewed as *supplementing and in no sense substituting for basic or long-run policies,* a primary function of which is to make compensatory measures less necessary. The more that basic fiscal and other measures (high wages, a tax system that is progressive but encourages risk-taking, prevention of abuses of monopoly power, etc.) can do to strengthen production incentives and broaden the distribution of purchasing power, the better.

[4] I am opposed to giving sales taxes, with their regressive character, any disproportionate emphasis in our tax system. However, if a special sales tax were linked with CSP in a two-way compensatory mechanism of the type here considered, the usual objection need hardly apply. The effect would be as progressive during periods when it was necessary to boost purchasing power as it would be regressive when necessary to hold purchasing power down; or more so, assuming sales tax exemptions for necessities.

current volume of consumer business.[5] (3) During periods declared to be "pay out" periods, retailers would give them to individual consumers as premiums on their purchases (value of purchase, times authorized percentage, figured to the nearest penny). (4) The individual consumer would redeem his CSP for cash at his bank or post office before the expiration date marked on the stamp's face. (5) Banks and the U.S. Post Office Department would return the CSP in bulk lots to the Treasury and would receive face value plus suitable compensation for their services as agents.

The administrative problems connected with such a scheme do not appear unduly formidable. The burden on retailers would be roughly like that of a sales tax—slightly more for bills mailed, since these upon payment would require a return receipt transmitting CSP. While there might be a number of CSP agents in a community, each retailer would normally have to choose one source of supply, and all lists of applicants would be cross-checked to prevent duplication. Each consumer would likewise normally deal with a single bank or post office selected by him. As a convenience and further precaution he probably would have a blank book issued to him, identified as his, to the pages of which his CSP would have to be affixed to be eligible for redemption in cash.

A numerical example will illustrate the effect on the economy as a whole. Assume aggregate consumer spending in year X underwritten at $300 billion, with the top limit set at $306 billion. Ignoring here the seasonal factor in sales, at least $75 billion should then be spent each quarter, or $25 billion each month. Assume that, after six weeks, the preliminary forescast for the first quarter showed only $72 billion. The responsible agency might then authorize CSP to be issued on all retail sales at a 10 per cent rate during months 3, 4 and 5. If monthly rates of consumer spending rose from $24 billion in months 1 and 2 to $27.3 billion in months 3, 4 and 5 (let us suppose that the inducement of obtaining CSP raised "ordinary" spending to $25 billion; add $2.5 billion CSP converted to cash less $200 million of extra saving from this extra cash), this would bring the five-month total to $129.9 billion, as against a target minimum of $125 billion, and the responsible agency might order termination of CSP payments at that point. The premiums might have to be issued again, at the same or a different percentage rate, later in the year. Or, if conditions changed markedly and total consumer spending for the year threatened to exceed the $306 billion limit, the responsible agency would bring into play the special sales tax or other agreed device for curbing a spending excess.

JOHN H. G. PIERSON*

[5] Purchases for business account would sometimes masquerade as consumer purchases. However, "leakage" in either a real or a statistical sense (in reduced leverage value for the economy, or in excess of transactions included for CSP over transactions included in the personal consumption expenditures aggregate) should prove relatively minor.

The Economics of *Scrabble*

This study investigates the applicability of certain general economic principles to SCRABBLE, a game assumed to be too well known to require description. The study is not an exercise in the theory of games; it is diametrically opposite to it. The theory of games takes its cue from the rather distressing proposition that the road to a proper theory of economic behavior passes through the study of the simplest of games, such as "Matching Pennies." The present paper radiates the much more self-satisfying philosophy that games, even such sophisticated games as SCRABBLE, can learn a lot from existing economics.[1]

In its relation to its subject, the study may well be compared to the economics of the firm. Mastery of this branch of economics is obviously not indispensable to satisfactory business management. But it helps the economist to understand what successful managers do; and it also helps managers to understand what they have usually been trying to do all along, and to do it better. Very much the same holds for the economics of SCRABBLE. Its mastery is not a substitute for the memorization[2] of *Webster's Unabridged;* but it helps.[3]

While some of the expositional devices used are borrowed from mathematics, the study is essentially economic in nature. Economics provides the analytical, as distinguished from the expositional, tools.

1. *The Proper Thing to Maximize*

One of the achievements of economics is to select the proper thing to maximize in each situation. As Samuelson has put it: "The study of maximizing behavior affords a unified approach to wide areas of current and historical economic thought."[4] Some businessmen might be inclined to maximize turnover; but clearly the wise thing is to maximize profit (or even better profit over time, suitably discounted). Some people might aim for maximum income; they should realize that what they really want is the optimum balance between income and leisure. While others might be satisfied to maximize some gross concept, the economist is always on the lookout for the costs and hence for the proper net concept to maximize.

In SCRABBLE, there is a clear gross target: to get as many points as possible. That is the objective which the inexperienced player tries to achieve *in each move.* Is there a cost?

2. *Alternative Use*

Economics points the way directly to what the "cost" element must be: alternative use. When a letter is used to make one particular word there is a sacrifice of the score that might have been obtained with the same letter in

[1] As in almost any use of tools in a new field, some refinement of the tools is found as a byproduct. See footnote 6.

[2] *Webster's New International Dictionary,* 2nd ed., unabridged, p. 1534.

[3] There is also a (relatively minor) strategy element in SCRABBLE, with which this paper does not deal.

[4] P. A. Samuelson, *Foundations of Economic Analysis* (Cambridge, 1947), p. 23.

another word. This is the key to the calculation of economic costs, which involves three steps.

Step 1. According to the information provided by the manufacturer, the total score of the game may be from 500 to 700 or more, or say, on the average, about 600. This is about three times the aggregate face value of all letters—187 for 100 letters, whose individual face values run from 1 (A, E, I, O, U, L, N, R, S, T) to 10 (Q and Z). This ratio, 3, we call the *multiplier* (M). A somewhat higher multiplier would be indicated for superior players.

Step 2. Ultimate value in the economic sense should be based on relative scarcity. We observe that the frequency of the letters in the game—from 12 E's to one each for J, K, Q, X, and Z, appears to be approximately in proportion to their frequency in the universe of the dictionary. It follows that their marginal usability to make words should be about the same, and hence their marginal utility, in terms of score value, should be proportional to their face value.

Step 3. Since (a) the total score value of all letters equals the multiplier times their aggregate face value and (b) their individual score values are proportional to their individual face values, it follows that the economic cost of an individual letter is found as the multiplier times the face value of that letter. With a multiplier of 3, for instance, a letter with a face value of 4, like H, must be reckoned as costing 12 if used in a particular score.

3. *Special Accounting Prices*

While decentralized cost calculations based on market prices may be assumed to perform tolerably well as an allocative device for most purposes, it is recognized in economics that sometimes prices other than those prevailing in the market, "accounting prices," have to be used to obtain a proper social optimum.[5] This principle has an important corollary in SCRABBLE. In the following instances there is ground for the use of special accounting prices, instead of face values, in computing costs. (a) To some extent the frequency of SCRABBLE letters may deviate from that in the real world, due for instance to indivisibilities (one feels that half a Q would be ample, and economists would like to have a chance to show off their training if they could once in a while get 2 K's to make "kinked"). (b) There are also letters that are particularly useful, like the S for making plurals. (c) There is, lastly, the particular skill of the player. To a player who has just memorized all the Z-words of the dictionary a Z has obviously a higher opportunity value than to one less erudite, and this should be reflected in his individual cost calculations regarding the use of the Z.[6]

[5] J. Tinbergen, "The Relevance of Theoretical Criteria in the Selection of Investment Plans," Conference on *Investment Criteria for Economic Growth*, mimeo. (Cambridge, 1954). Also for a particular application to the exchange rate: H. B. Chenery, "The Application of Investment Criteria," *Quart. Jour. Econ.*, Feb. 1953, LXVII, p. 76-96.

[6] This points to a necessary elaboration of Schumpeter's theory of the entrepreneur. His 19th century entrepreneur was apparently satisfied to pursue any reasonably handsome profit by introducing some new combination while buying factors of production on the

4. *Replacement Letters*

The analysis of cost has proceeded so far on the assumption that a letter used has to be calculated fully as a cost item. But, under the Rules, each letter used is replaced by another one. Since each replacement letter is drawn face down, its value cannot be known: the theory has to be based on its *probable* value being the *average* value of all letters,[7] *i.e.* 187 ÷ 100 or, after rounding, 2. Allowing for replacement we find that a letter used has a *net* cost of multiplier × (face value[8] − 2).

By an involved process of reasoning it can be shown that no allowance is necessary for the fact that by drawing, say, x letters from those still remaining, a player reduces the number of letters that he will be able to draw in the future. At first sight it would seem that he does reduce his ultimate supply of letters by a number which might be approximated as $\frac{x}{n}$, n being the number of players. This would set him back in score by $\frac{2Mx}{n}$, 2 being the rounded estimated probability value of each letter foregone. But further consideration leads to the conclusion that not only this player, but *every* player, will lose $\frac{x}{n}$ letters as a result; and assuming, as a first approximation, that all play equally well, *i.e.*, that they operate with the same M, each will lose $\frac{2Mx}{n}$ in score. If then our player's objective is to win, rather than to amass the largest absolute number of points, any adjustment that applies equally to all players may be disregarded. We should note, in passing, the important finding that, since n will not appear in our formula, the economically best way of playing SCRABBLE is independent of the number of players.

5. *The Formula*

Summarizing the above we find that a player should maximize at each move his profit P, computed as follows:

$$P = S - M \sum_{i=1}^{i=x} (v_i' - 2), \qquad (1)$$

basis of their cost (= opportunity value when used in the circular flow) But the man who has a variety of tempting entrepreneurial possibilities among which his staff must choose must obviously calculate as part of the cost of any one of them the profit to be made in a "normal" entrepreneurial exercise As Mr. Wolfson (to quote a 20th century entrepreneur rather than an economist) stated to *Life* about his only business mistake, making several hundred thousand dollars in movies: "But we took a couple years to do it and that's tying up too much time and capital for that size result." (*Life*, Nov 22, 1954, p. 179).

[7] Making no adjustment for any possible difference from the average of the letters that have already been drawn earlier in the game.

[8] Adjusted face value where appropriate.

where: S is the score to be made in the move
M is the multiplier (about 3), and
v_i' is the (adjusted) face value of any letter i ($i = 1, 2, \ldots x$) used.

6. *Practical Application*

A. *Choice between alternative simultaneous possibilities.* Formula (1) is easily applied in practice to decide which of various alternative possibilities yields the highest P. It takes little time or skill to subtract 2 from the face value of each letter to be used, to add up the results and to multiply by 3.

Since our formula, through use of the cost principle, allows for the value of future use, it also indicates whether, where there is any choice, an additional letter should be used, or whether it is more profitable to save it for later. For this purpose, however, the formula can be considerably simplified.

B. *Intertemporal allocation.* For this purpose we transform the formula into an expression for the marginal profit attributable to the use of an individual letter (P'), as follows:[9]

$$P' = kv - 3(v - 2) \qquad (2)$$

where $k = 1, 2, 3$, depending on whether the score made with the letter is single, double or triple. This reduces to:

$$\left.\begin{array}{ll} P' = 6 - 2v & k = 1 \\ P' = 6 - v & k = 2 \\ P' = 6 & k = 3 \end{array}\right\} \qquad (3)$$

From this follow a number of rules:

Rule I. Letters with face values of 1 and 2 *should*, and letters with face value of 3 *may*, be used whenever there is an opportunity. Even when they score singly, they will yield a nonnegative profit.

Rule II. Letters with face values of 4 and 5 should not be used unless they score at least double—(but do not wait for triples!)

Rule III. Letters with face values of 8 and 10 should be kept for triple scores, but with two very important qualifications: (a) Only a small discount for their adjusted value (v') below v is necessary to justify, *i.e.*, to compel, use of these letters if only a double score is the best that can be made.[10] (b) No allowance has been made so far for the fact that the game is in practice played with a finite number of letters, and that a penalty attaches to remaining stuck with a letter at the end of the game. For these high-value letters with limited usefulness a correction for this is needed (for other letters its

[9] Assuming $v = v'$ *i.e.*, face value equals accounting value

[10] The required discount is derived from (2), taking $k = 2$ and stipulating $P > 0$:

$$2v - 3v' + 6 > 0$$
$$v < 2/3v + 2$$
$$\text{For } v = 8,\ v' < 7.33$$
$$v = 10,\ v^1 < 8.67$$

effect would be negligible). It consists in subtracting from the cost of using the letter now an estimate of the probable loss at the end of the game due to the impossibility to use the letter in the future. The amount involved is $q^m \cdot v$, where q is the probability that one cannot use that letter in one move, and m the estimated number of moves the player expects to have ahead of him. If, for instance one can use a Z ($v = 10$) only once every five moves ($q_z = .8$) and one expects to have only four more moves left, the correction would be $.8^4 \times 10 = 4.1$. This would make P' just positive for $k = 2$.

These Rules are by no means self-evident. Thus Rule II is violated in one of the few examples which the manufacturer provides with each set. In this example an F ($v = 4$) is used, without necessity, to yield only a single marginal score.

Despite the theoretical complications involved in the derivation of these Rules, it will be found that they can easily be followed in practice, even by beginners.

J. J. POLAK

Dollar Pooling in the Sterling Area: Comment

In a recent article, "Dollar Pooling in the Sterling Area,"[1] Kenneth M. Wright has made an excellent contribution to the understanding of one important aspect of the sterling area. There are several comments, however, that might usefully be made.

Wright states that "one major qualification" is necessary to the tables he presents on the sterling countries' yearly positions with respect to the dollar pool. This qualification is that because of the intrasterling-area transactions in "dollar-saving exports" the country figures, even if perfect,[2] would not show the "true contribution" which each country has made to the problem of the entire sterling area's dollar shortage.[3]

I think that there is a more important qualification that needs to be made. The contribution a sterling-area country is making towards the solution of the entire sterling area's dollar shortage must be measured not only by its bilateral position vis-à-vis the dollar area but by its global balance of payments. This latter provides a measure of the degree to which the country makes necessary a drain on the external resources of the area or contributes to building up the external resources of the area. Note, for example, that in

[1] *Am. Econ. Rev.*, Sept. 1954, XLIV, 557-76.

[2] Wright mentions that the dollar accounts of the sterling-area countries other than the United Kingdom are underestimated when these countries do not take account of dollar goods received through intermediaries in the United Kingdom. The share of the United Kingdom is also exaggerated because: (a) The dollar cost and proceeds of goods that undergo processing in the United Kingdom and that enter into intrasterling-area trade are allocated to the United Kingdom in the U.K. balance of payments accounts; (b) The whole of the British oil companies' production expenditure in dollars is allocated to the United Kingdom in the British accounts though much of the output is consumed in the rest of the sterling area; (c) Dollar investment in the rest of the sterling area by American companies often appears in the balance-of-payments statements of those countries (*e.g.*, Southern Rhodesia) as the receipt of sterling.

[3] Wright, *op. cit.*, p. 573.

Wright's Table I, the biggest single drain on the central reserves over the period 1946-52 was "Transactions with nondollar areas on whole sterling-area account." These were gold and dollar payments made necessary by the position of the whole sterling area vis-à-vis a particular country or area which converted into dollars or gold only a part of its sterling receipts, *e.g.*, the European Payments Union. During this period such gold and dollar payments were made at one time or another to most of the nondollar nonsterling world.

The January 1954 Commonwealth Finance Ministers' conference emphasized in its final communiqué that while the sterling-area countries should maintain their efforts to achieve a dollar surplus directly, it was just as important to earn a substantial surplus in other nonsterling currencies.[4]

With the expansion of the transferable sterling account system to almost the whole of the nondollar nonsterling world in March 1954 there can be seen even more clearly the important influence the nondollar part of the sterling-area countries' balances of payments exerts on the dollar position of the sterling area. If the sterling-area countries make available too much sterling to the rest of the world, the central dollar reserves are sure to suffer. Transferable sterling becomes cheap in New York and commodity shunting begins:

> . . . a sterling commodity is sold by a Continental merchant to the United States. He wins the business on competition with a British merchant because he uses a cheaper type of sterling and can therefore offer a lower price. The dollars he gains are lost to the sterling area; they are reconverted into sterling in the transferable market.[5]

Also,

> . . . there is no difficulty about the import into this country [the United Kingdom] of many dollar commodities which are then reexported to the continent against payment in sterling.[6]

The sterling part of the balance-of-payments accounts of a sterling-area country is also important. An obvious example: if India has a balance with the nonsterling world but a deficit with the United Kingdom financed by drawing down its sterling balances, it will absorb British products which might have been sold for dollars.

I think that the foregoing should be sufficient to make the point that in assessing the contribution made by a sterling-area country to the dollar position of the whole area, it is necessary to consider not only its dollar accounts but its global balance of payments.

On the other hand, I do not feel that the principle cited by Wright (p. 573) that "exports to sterling countries which save dollars for the common reserves

[4] The need for improving the global balance of payments has been repeatedly emphasized by the Commonwealth Finance Ministers' conferences. The December 1952 conference, for example, stated: "An adequate and stable external balance must be a first objective for all Governments."

[5] "Shunting Backwards," *The Economist*, Feb. 12, 1955, CLXXIV, 557-8

[6] *Loc. cit.*

are as valuable as exports which earn dollars" has much meaning in this type of analysis.[7] It is perfectly true that on a few occasions countries in the sterling area have tended to advance this as a kind of justification of their position when they were showing heavy dollar deficits. The virtue of this "principle"—and its fundamental defect—is that almost everything can be plausibly cited as being a dollar-saving export. When Australia provides wheat to England and England provides machinery to Australia both can feel a glow of satisfaction for thus saving dollars for the common reserves and at the same time continue to be net drawers of dollars from the dollar pool.

The dollar accounts of a sterling-area country and its net position vis-à-vis the dollar pool can be more or less ascertained. Similarly its global balance of payments can be ascertained and these two together provide a basis for a judgment of the contribution that each member is making to the solution of the area's dollar problem. And, of course, as the world currencies became more and more convertible *de facto* the latter element becomes more and more important. There is no need for any attempt to assess the purely hypothetical dollar-saving elements in intrasterling-area trade.

On the whole, although Wright's discussion of the position of the outer sterling-area countries is good, a few slips have occurred in treating the position of the Colonial territories.[8]

A fairly serious error occurs in two places: on page 569, he says, the dollar contribution of the colonies ". . . is slightly more than the rise in sterling balances held by the colonies since 1946, and in effect, represents a rather curious capital movement from the colonies to the United Kingdom in the form of dollar exchange." On page 574, he says, "Lacking autonomy in their own dollar-import policies,[9] they [the colonies] have contributed almost $2 billion to the pool in 1946-52 and have accumulated sterling balances of roughly equal size during the same period. The colonies have thus been exporting capital to the United Kingdom in the form of dollar exchange." This point is a good example of a *non sequitur*. The fact that colonial sterling balances have increased does not necessarily mean that the colonies as a bloc have been exporters of this amount of capital to the United Kingdom (though several of the colonies have exported capital to the United Kingdom during this period). It could even mean that the United Kingdom has made more capital available to the colonies as a whole than the colonies could absorb.[10]

[7] One possible exception—and it would apply to only a few cases—would be where a sterling-area country in choosing between two new investments, each yielding the same return, would choose the one that would produce a replacement for dollar goods.

[8] For example, he says on page 561, "Colonial dollar earnings are surrendered to the local exchange controls and transferred to the Bank of England or its authorized dealers." The typical case, in fact, is rather that of a colony whose foreign trade is handled by banks with head offices in London or by trading or producing companies with headquarters in London. The dollars earned by exports to the dollar area never see the colony but stay in London. The local producers get the money they want—local currency or sterling balances.

[9] It is not correct to say that the colonies lack autonomy in their own dollar import policies. It would be more accurate to say that the colonies are more amenable to persuasion on this than are the fully independent members of the Commonwealth.

[10] *Cf.*, movement in European gold and dollar reserves during Marshall Plan period.

To illustrate my point by a particularly fortunate example: in 1953, the colonies, excluding Hong Kong, had a deficit on current account of £15 million,[11] yet colonial sterling balances, excluding Hong Kong, went up by £57 million.

There are some corrections in Table III on page 571 that Wolfgang Weigel has called to my attention: Table III shows a gold and dollar contribution to the central reserves by Australia in 1950 of $24 million. It should be $54 million. The difference is equal to the amount of gold sales to the United Kingdom which were probably not taken into account. Pakistan's drawings are shown as $11 million too high in 1951, and too low in 1952. This is probably because the $11 million gold purchase was ascribed to 1951 while it actually occurred in 1952. The same is true of the gold purchase of $11 million by Ceylon. It occurred in 1951 rather than 1950. In 1952, the figure for Southern Rhodesia is $15 million too low, perhaps by reason of the omission of gold sales of this amount to the United Kingdom. Footnote *ii* of the table states that statistics were not available for several countries, among these Iceland and Iraq: regional balance-of-payments data are available for Iceland in the *Balance of Payments Yearbook* of the International Monetary Fund. Published figures are also available for Iraq for the years 1951 and 1952 in the *Quarterly Bulletin of the National Bank of Iraq*, Nos. 3 and 7.

Dollar Pooling in the Sterling Area: Comment

K. M. Wright's article, "Dollar Pooling in the Sterling Area" in the September 1954 number of this *Review* is a useful and interesting account of the policy declarations and statistical results of the "dollar pool" which has been functioning in the sterling area. However, his interpretation of the position of the British colonies in the pool's operations is apt to be misleading because it ignores certain important conditions that underlie the financial results tabulated in the Balance of Payments White Paper. I refer in particular to his statement, "United Kingdom colonies were of great importance in bolstering the dollar reserves between 1946 and 1952. Their contribution is slightly more than the rise in sterling balances held by the colonies since 1946, and in effect, represents a rather curious capital movement from the colonies to the United Kingdom in the form of dollar exchange" (p. 569), which is later amplified, "For the colonies, however, dollar pooling has had serious drawbacks. Lacking autonomy in their own dollar import policies, they have contributed almost $2 billion to the pool in 1946-52 and have accumulated sterling balances of roughly equal size during the same period. The colonies have thus been exporting capital to the United Kingdom in the form of dollar exchange" (p. 574).

As Mr. Wright also states, however, not all the colonies have been net contributors to the dollar pool. Some have run substantial deficits, and many have not had significant balances either way. Clearly, therefore, they have

not all suffered hardship of the same kind or for the same cause. Nor has their lack of autonomy had a uniform effect upon their dollar expenditures. This lack of "complete autonomy" in foreign exchange policy is a logical consequence of the colonies' general monetary relationship to London, and in comparing their position to that of the "independent members of the sterling area" it should be remembered that the colonies are in practice overseas parts of the United Kingdom monetary system, and have no responsibility for maintaining foreign exchange reserves or taking any other measures that would affect the value of their own currencies. Moreover, they did not have rationing and tax controls on consumption in the postwar period to the same extent the United Kingdom did, and hence import licensing was practically the only method of controlling the demands (reflecting war-inflated incomes) for goods and currencies of which there was a global scarcity. The colonies have been notable beneficiaries of the postwar rise in raw material prices, and this has played an important part in increasing the level of international monetary reserves which it has been necessary for London as the banker for the sterling area to hold.

But while the colonies had to pursue the same fundamental policy of exchange control as the United Kingdom, every colony had its own government department for administering its import and currency regulations with some discretion as to the actual goods that were admitted or excluded. And these separate administrative methods led to a wide variation in local control practices. Underlying the major differences in dollar expenditure were of course the differing needs between colonies for essential imports. The West Indies, for instances, had to have flour from Canada, and Jamaica built tourist hotels with United States materials, but in the West African territories such imports were not of the same urgency. There may be room for doubt as to whether the operations of the local controllers had ideal results in every colony, but their existence did mean that the total dollar expenditure of each colony as well as the particular goods imported depended in some degree upon the case the local authorities presented to London and the decisions they made in issuing permits to applicants.

The central error in Wright's argument, however, is his insistence that the automatic consequence of contributions to the dollar pool was a corresponding export of capital by the colonies to the United Kingdom. For evidence of this relationship he seems to rely on the statistics of rising colonial "sterling balances" since 1946, although it is easy to find a superficial defect in this reasoning in the fact that colonies with dollar deficits as well as those with dollar surpluses have been increasing their sterling balances. In reality the two processes of regulating dollar expenditures and acquiring London assets are quite distinct. The colonial recipients of dollar exchange pay it into their bank and receive an equivalent amount of sterling which they are free to spend for any purpose except prohibited imports. The fate of the dollars contributed to the pool is quite independent of the use ultimately made of their sterling equivalent. And independent also of contributions to or drawings from the pool is the accumulation of the government and banking assets known as sterling balances. These are chiefly the consequence of colonial

government methods of finance which involve holding liquid and invested funds in London, and they are related to the system of internal taxation, not to foreign exchange control. They derive from taxes raised in each colony, from deposits in savings and commercial banks, and from such special items as the reserve funds of the postwar Commodity Marketing Boards. These colonial sterling balances have nothing in common with the similarly classified wartime accumulations of some other parts of the sterling area, and their increase is a reflection of general economic conditions since the war. Colonial residents who receive sterling in exchange for dollars are free to invest it in other parts of the sterling area, and most of this investment goes through London, but the assets of private investors are not shown in the official statistics of sterling balances to which Wright refers. That is to say, these statistics do not include the whole of the capital movement from the colonies to London. They do, however, aim at showing total dollar transactions. That the *ex post* record on this basis should make the colonies appear to be deprived of dollars—and capital—to exactly the same extent that they acquired sterling balances seems to be one of those results that Hollywood calls entirely coincidental.

If we want to attribute monetary implications to the statistics of colonial trade it is important to remember that the recorded import-export figures for each colony do not show with exactitude either the currency receipts available to people in the colony or the total claims on dollar sources represented by its imports. This discrepancy arises for two reasons. One is that a part of the proceeds of certain exports, *e.g.*, rubber, tin, copper, lead and zinc, tea, sugar, etc., go to company funds and investors in the United Kingdom where the producing concerns are owned and controlled, and hence the total value of exports is not distributed to people in the colonies for spending on goods from any source. The colonies showing a significant dollar surplus are those where there is a substantial United Kingdom investment in export production. The other reason is that the imports of most colonies include a high proportion of manufactured goods from the United Kingdom which incorporate part of the United Kingdom's own dollar imports of raw materials and components, particularly cotton, wheat, tobacco, paper and chemicals. And in this connection it must be recalled that consumption in general was not so restricted in the colonies in the postwar period as it was in England, and people in the former could buy all they could afford from sterling sources, even when people in the United Kingdom could not.

In claiming further (p. 574) that "broadly speaking, the United Kingdom has been able to maintain its capital exports to the independent sterling countries only by passing on to them much of the dollar aid received during the early postwar years, and by importing capital from the colonial sterling area in more recent years," Wright seems to ignore the steady flow of both private and public capital to the colonies since the war. Investment in many large-scale industries has been increased. For instance, in oil, bauxite, copper and base metals, gold, diamonds, sugar and sisal, and also in light and power installations, in harbors, docks, roads and railways, and a variety of minor industries. Several colonial governments have raised loans in London, and

some municipal issues have been floated there for the first time. In addition to these market transactions there have been two special organizations, the Overseas Food Corporation and the Colonial Development Corporation, established for making investments with Treasury funds, and the colonies have made regular drawings from the development and welfare funds voted by Parliament. Also, there are always emergencies and disasters, such as floods, famines and hurricanes, for which *ex gratia* payments are made by the United Kingdom. Detailed information on these matters is given in the Secretary of State's annual report to Parliament on the Colonial Territories.

In the postwar decade a vigorous policy of economic development has been pursued in most parts of the Commonwealth, and dollar drawings from the pool have in large part been determined by the import requirements of this policy. For various reasons, not all monetary, the colonies have obtained most of their capital imports from the United Kingdom, but this fact alone is not evidence that their development plans and projects have been handicapped by lack of dollars. It is an error of still wider implications to think that the United Kingdom depends for maintaining its international economic position upon the capital it arbitrarily "imports" from the colonies. This is to misrepresent not only the monetary position of the colonies but also the whole problem of sterling.

IDA GREAVES*

* The author has recently made studies of colonial monetary conditions and colonial capital formation for the Colonial Economic Research Committee, London, England

Reply

Although the points raised in the comments of Miss Greaves and Mr. Kamarck are interrelated, I will discuss separately each of the major questions raised by them.

1. Miss Greaves asserts that colonial sterling balances "derive from taxes raised in each colony, from deposits in savings and commercial banks, and from such special items as the reserve funds of the postwar Commodity Marketing Boards." Although sterling assets held by colonies may be classified in terms of ownership in this manner, this approach obscures the fact that sterling balances rise or fall primarily as a result of the balance of payments of the colonies. Whether net export proceeds are deposited in savings and commercial banks, or taxed by colonial governments, or kept as reserves by the marketing boards and price assistance funds does not matter in this context—colonial balances nevertheless arise largely from external transactions.

2. Sterling balances owned by the colonies are the financial counterpart of the real resources to which the colonies have a claim, but have released to others; instead of using these resources at home, the colonies have allowed others to use them. In this sense, the colonies are net exporters of capital when there is a rise in colonial sterling balances. When the colonies have a dollar surplus and contribute such dollars (as well as gold) to the dollar pool, the transaction may be considered as a release of claims over dollar goods and

therefore an export of capital in the form of dollar exchange; in exchange for dollar claims, sterling balances are increased. At the same time, of course, the colonies may be incurring deficits with nondollar countries and drawing down sterling balances by reason of such deficits, representing an import of capital in the sense outlined above. Taking both dollar and nondollar transactions together, the colonies could be either net exporters or net importers of capital vis-à-vis the rest of the world (and therefore increasing or decreasing sterling balances), depending upon the size and direction of the two types of transactions.

The only available statistics that use consistent definitions and coverage for the external colonial transactions are those for transactions with the dollar area (on current and capital account) and for the changes in colonial sterling balances, shown in Table I. These data reveal a parallel movement in

TABLE I.—COLONIAL EXTERNAL TRANSACTIONS
(in millions of pounds)

	Transactions with the Dollar Area	Change in Colonial Sterling Balances
1950[a]	+156	+172
1951	+174	+195
1952	+139	+104
1953	+101	+ 68
1954	+108	+124
1950–54	+678	+663

[a] Includes Northern Rhodesia, which is subsequently excluded from the balance-of-payments definition of "United Kingdom colonies."

Source. Cmd. 8976, *United Kingdom Balance of Payments, 1946 to 1953* (London: HMSO, 1953); Cmd. 9430, *United Kingdom Balance of Payments, 1946 to 1954*, No. 2 (London: HMSO, 1955).

the rise in colonial sterling balances and the colonial contributions to the dollar pool resulting from current and capital transactions with the dollar area (including gold sales to the United Kingdom). What is missing in these accounts is (a) colonial current accounts with the nondollar world,[1] and (b) colonial capital accounts with the nondollar world. Data which are not fully consistent with those of the table indicate that the colonies incurred rather sizable current-account deficits with other sterling-area countries; these deficits were probably offset in part by an inflow of financial capital from nondollar countries (mainly the United Kingdom). It would appear that nondollar colonial transactions on current and capital account largely washed each other out; consequently, the dollar contributions of the colonies may be

[1] Data on the colonial current accounts since 1950 are available in the Colonial Office reports on *The Colonial Territories*, published yearly, but comparison with data on colonial dollar transactions is prevented by differences in coverage. For example, Hong Kong is excluded from colonial current account statistics, while the Rhodesias are excluded from the definition of "United Kingdom colonies" in the United Kingdom balance-of-payments statistics on colonial dollar transactions and colonial sterling balances.

considered as primarily responsible for the increases in sterling balances over this period. The only other candidate for this role, suggested by Kamarck, is the flow of unabsorbed financial capital to the colonies from the nondollar world, but fragmentary data indicate that this factor is only a runner-up far behind in the competition. Although the changes in sterling balances and the transactions with the dollar pool obviously do not match up year by year and colony by colony, since a host of other factors comes into play, I still submit that it is valid to view the colonial dollar contributions both as exports of capital in the form of dollar exchange, and as a strategic factor in the postwar rise in colonial sterling balances.

3. Regarding the degree of autonomy over import policies which the colonies possess, Miss Greaves declares that every colony had "some discretion as to the actual goods that were admitted or excluded," and that "the total dollar expenditures of each colony as well as the particular goods imported depended in some degree upon the case the local authorities presented to London. . . ." But this description does not tell us how far such autonomy went in practice. Available statistics reveal that colonial dollar imports did not in fact keep pace with those of other members of the sterling pool during the greater part of the postwar period, as may be seen from Table II.

TABLE II.—STERLING AREA DOLLAR IMPORTS

	Millions of U.S. Dollars			1948 Value = 100		
	United Kingdom	U.K Colonies	Other Sterling Area*	United Kingdom	U.K Colonies	Other Sterling Area*
1948	1,634	310	875	100	100	100
1949	1,606	220	805	98	71	92
1950	1,206	135	590	74	44	67
1951	2,055	215	1,100	126	69	126
1952	1,668	195	1,165	102	63	133

* Excluding South Africa, which did not coordinate its dollar import policies with the rest of the sterling area.

Source: Cmd. 8976, *United Kingdom Balance of Payments, 1946 to 1953* (London: HMSO, 1953). The 1948 base is appropriate because sterling area dollar import restrictions had been universally tightened following the 1947 convertibility crisis

4. As to whether the international position of sterling has been misrepresented by an emphasis on rising colonial sterling balances, I can only suggest that the reader imagine the position of sterling should the colonies begin drawing down balances at the rate they have been built up, and also become drawers on the dollar pool to the extent that they have been contributors in the past. Several other points raised by Miss Greaves do not seem to relate to my article, and although I disagree in part. I feel that no reply to them is called for.

5. I can agree with Kamarck that in a regime of convertible currencies the global balance of payments of a sterling country is an important criterion in

measuring a country's contribution to the external position of the entire sterling area. However, in the lopsided world of inconvertibility, the payments position vis-à-vis certain currency areas cannot be ignored, and a somewhat lopsided treatment of the problem becomes highly relevant. Kamarck points to the drain on central reserves arising from transactions with European Payments Union countries requiring partial payment in gold or dollars. But the distinction between dollar transactions and EPU transactions is one of degree not of kind from the sterling-area viewpoint. Deficits with the dollar area produced a roughly equivalent drain on the central reserves, while deficits with EPU countries led to partial drains on reserves, depending upon the quota position of the sterling area in the EPU at any given time. My article was devoted to the measurable aspects of contributions and drains on the dollar pool by sterling-area members, but the drain through EPU transactions (and transactions with other nondollar, nonsterling countries) does not lend itself to measurement by sterling countries, important as it was in the reserve problems of the sterling area. As Kamarck states, "as the world currencies become more and more convertible *de facto* the [global balance of payments] becomes more and more important." I agree, but sterling was not convertible during most of the period discussed, and the distinctions drawn in my article certainly apply.

6. The "principle of dollar-saving exports" was included in my analysis as an illustration of the pitfalls in measuring dollar contributions with the available statistics, but was not intended to exclude other statistical shortcomings such as those Kamarck points out. The "principle" does, I think, lead directly into the insuperable problem of measuring dollar contributions in the thorough-going economic sense, and I am certain that the extent to which each transaction of each sterling country does save dollars cannot be accurately measured. The question appears to be how far such analysis should be carried; Kamarck seems to suggest that it should never be attempted. As a solution, he proposes that both dollar accounts and the global balance of payments for each sterling country be examined as a basis for judging the contribution of each member to the sterling area's dollar problem. I believe my article has at least brought together the dollar accounts, but it is not clear to me what sound "judgment" could accurately be made by examining them in conjunction with global accounts for each sterling-area member, or whether two separate and objective "judgments" would produce the same opinion.

BOOK REVIEWS

Economic Theory; General Economics

Man, Motives, and Money—Psychological Frontiers of Economics. By ALBERT LAUTERBACH. (Ithaca: Cornell University Press. 1954. Pp. xvi, 366. $5.00.)

Over many centuries, discourses on economic affairs have included explicit or implicit theories of human nature, of motivation, of calculations as to monetary costs and returns and as to utility and disutility. Psychological variables or aspects of economic life have been treated in innumerable book-sections and articles, but not many authors have felt called to the task of treating such matters at book length. Thus, the appearance of the volume here reviewed, soon after that of Katona's *Psychological Analysis of Economic Behavior,*[1] is an event of much interest.

Lauterbach, a teacher of economics, has had some associations with Katona and others in the University of Michigan Survey Research Center, and, as appears below, he uses some of the Center's output. It seems, however, that the bulk of his equipment and interpretations represent other trends in research—notably what we might designate as psychiatric sociology. Anthropological and comparative-economic materials are also fed into his hopper. Although the history invoked is mostly recent, in general his outlook is reminiscent of historical and institutional discussions of economic premises and methodology. His achievement, he says (p. 236), is "not by any means a general theory of economic psychology"; its "aspiration is far less ambitious. . . . The author feels no more ready to present any such theory than do most other researchers right now. He is also uncertain whether the disciplines concerned have cleared the way toward it sufficiently at this juncture."

The book includes eleven appendixes, a majority of which are derived from Survey Research Center publications, on such matters as industrial relations, views of large and small businesses, labor unions, and government, and "war dangers and worries." (This last phrase is in line with Lauterbach's strong emphasis on the incidence of personal insecurities.) One appendix appears to be based on a psychiatrist's notes; another, entitled "Incentives in Nationalized Plants in Austria," is based on interviews in that country by Lauterbach in 1950. The Survey Research appendixes contain tabulations, and these are given some discussion in the text-chapters; but in general Lauterbach does not display much enthusiasm for the quantitative psychological material now available. (But we must remember that the expenses of money, time, and effort involved in significant quantitative social research are prohibitive for most professors.) In addition to the novel material from the author's Austrian interviewing, this book contains many reflections of his cosmopolitan, polylingual background; and his writing is remarkably fluent

[1] Reviewed in this journal, Dec. 1953, XLIII, 931-33.

and clear, considering his tendency to manipulate more or less psychiatric concepts such as "parental images" and the numerous varieties of inferiority and insecurity states of mind.

In a few pages of introduction, three sets of problem-questions are indicated as giving the scope of the book. They begin as follows: "(1) To what extent does business behavior in our existing society actually follow those rules of economic decision making which economic analysis has assumed or developed? . . . (2) Assuming that economic instability, intentionally or not, is a concomitant of a private business economy, to what extent and in what ways has such instability prevented individuals and groups from acting 'economically'? . . . (3) To the extent that any such hope is legitimate, does economic reform of any desirable type presuppose a different kind of human being from the one that we have known thus far, especially in Western democratic countries? . . ." These themes are treated through four lengthy chapters, which are followed by a fifteen-page chapter of "Summary and Conclusions." (Here I recall Commons' remark, in *Industrial Government,* as to why he called the final chapter "Inferences" rather than "Conclusions.")

The language here quoted from the introduction almost suggests the author's (tentative) answers. Like many other "discussants" of such matters, Lauterbach finds actual behavior in business enterprises extremely variable, in part by reason of differing sizes of firms; and his conception of "those rules . . . which economic analysis has assumed or developed" appears to give insufficient weight to the institutional elements which are rather prominent in, *e.g.*, Mill and Marshall. Sensible economists have long, if not always, realized that the simple "model" of the immediate-profit-maximizing "economic man" is at best only a bare framework for the beginning of analysis of "capitalist" economy. And with reference to the second question quoted above, we may find much of interest and importance in Lauterbach's discussion of instability and insecurity. The phrase, however, "concomitant of a private business economy" might well lead to more consideration of the extent to which conversion of private-profit-seeking enterprise into private-nonprofit and governmental enterprises may be expected to effect a net reduction of insecurities.

The foregoing comments may indicate some of my notions as to important ingredients somewhat underrated in Lauterbach's treatment of his third group of questions—more directly concerned with motivation and reasonable expectations as to social-economic reforms. But on the whole his discussion here seems distinctly enlightening. He holds, of course, that a considerable range of (specified) targets of amelioration may be approached without "presupposition of a different kind of human being"; and through the book considerable research material is indicated as supporting this view. His optimism, however, is restrained and cautious, leaning perhaps toward the view that large enterprises such as the hydro-electric power project, about which he interviewed people in Austria, are most likely to be suitable for government ownership—if the public bureaucracy averages as high in ability and probity as the big-business bureaucracies of the nation concerned.

Z. CLARK DICKINSON

University of Michigan

Das Konkurrenzproblem im Oligopol. By RUDOLF RICHTER. (Berlin and Munich: Duncker and Humblot. 1954. Pp. 112. DM 8.00.)

The first half of this recent German contribution to the theory of oligopoly consists of an extensive and clear account of ten versions of the theory, *i.e.*, the models presented by Cournot, Bertrand, Hotelling, Frisch, Chamberlin, Stackelberg, Schneider, Kaysen, Fellner, and Brems. According to Richter, all are unsatisfactory, either because they assume the existence of a reaction function that is bound to turn out to be invalid, or because their solutions are merely subjectively, but not objectively, rational.

Richter's positive contribution is as follows. There are two distinct problems to be solved, one at the industry level, one at the firm level. Industry behavior is a matter of fixing the price of the industry's product, price and product being assumed to be common to all firms. Under such assumptions it is legitimate for Richter to draw a downward-sloping industry demand curve. At what point will industry fix its price? The reasoning here is far from clear, but let us reproduce it for what it is worth. Once the industry price had been set, industry sales would have been determined, and firms would regard firm revenue as being in direct proportion to the firm's quantity sold. Assume that production cost and selling cost as well are in direct proportion to quantity sold. Profits will then be in direct proportion to quantity sold and thus to firm revenue. So far we can follow Richter without difficulty. But then he says that since in an oligopolistic market the emphasis is on revenue and market share (one firm can gain revenue only by depriving another of revenue), then industry price is best set at the point where industry revenue is maximized. Richter seems to be aware of the fact that when costs exist industry revenue is maximized by a lower price than industry profits, but he does not convince his reader that industry revenue rather than industry profits should be maximized.

The second problem is to determine firm behavior. Once the industry pie has been determined, firm behavior will determine the slices of the pie falling to each firm. What are the variables used for this determination? Price being now beyond the control of the firm, and quality of product being assumed to be constant and identical as among firms, only advertising remains. But even here there is the constraint that advertising cost per unit of product sold must remain constant. So firms fight for market shares not with advertising budgets but merely with good ideas as to how to spend those budgets. Jastram is quoted in defense of this assumption which sounds quite realistic.

The stage is now set for the determination of firm behavior. A solution is found in the theory of the zero-sum two-person game as originally developed by von Neumann and Morgenstern. The game is two-person, because duopoly is the only case considered by Richter, and it is zero-sum because of a neat little trick. A's result of the game is defined by Richter as A's revenue *minus* B's revenue, $r_A - r_B$. B's result is defined as $r_B - r_A$. Under the set industry price, industry revenue $r_A + r_B$ is constant; call the constant K. Then $r_A - r_B = 2r_A - K$, from which we can see that what maximizes r_A will also maximize $r_A - r_B$. Likewise it can be seen that what maximizes r_B will also maximize $r_B - r_A$ or, which is the same thing, minimize $r_A - r_B$.

Hence the profit maximization game is zero-sum, for under constant price and constant per-unit cost of production and selling what maximizes revenue also maximizes profits.

Richter now introduces the assumption of perfect information in the strictly technical, *i.e.*, von Neumann-Morgenstern sense. This means that each player who makes a personal move is perfectly informed about the outcome of the choices of all anterior moves by his adversary. Van Neumann and Morgenstern, as we know, have shown that in games in which perfect information prevails, permanently optimal, pure strategies exist. Disliking the mixed strategies, Richter is very fond of this result. It permits him to reach a purely objective solution of his problem. No estimates of probabilities of rival action, no reaction curves, no attempts to find one's adversary out!

Apart from the maximization-of-industry-revenue procedure, where the reader may be pardoned for remaining unconvinced, Richter is correct within his own assumptions. But how narrow are the confines of those assumptions? Imagine a game in which every move requires careful and time-consuming preparation and, consequently commitment long in advance. Perfect information is ruled out by the very nature of the game, and there is a high premium on finding out the adversary. Suppose the German High Command had found out the time and place of the Normandy invasion, or the Allied Command the time and place of the Battle of the Bulge!

When facing a situation like this, the theorist can do two things. He can face reality squarely and come out with a subjective rationality. Or he can insist upon objectivity and refuse to admit any phenomenon which could play havoc with his assumption of perfect information. In oligopoly, one such phenomenon is product-quality variations, for they require research, designing, production engineering and tooling-up; in short they require commitment far in advance. Although he emphasizes the nonprice variables, Richter refuses to consider the quality of the product as a variable. The exclusion of quality variations is defended in the interest of "the exactness of our analysis."

As an exercise in objective and exact solutions, and as one of the few applications of the theory of games to oligopoly, Richter's book is useful, not the least because it clearly reveals the frightening height of the price that must be paid for objectivity and exactness.

HANS BREMS

University of Illinois

Economics and the Public Interest. Edited by ROBERT A. SOLO. (New Brunswick: Rutgers University Press. 1955. Pp. xiv, 318. $5.75.)

This is a collection of twenty essays, plus a short preface by Arthur F. Burns, contributed by former students and colleagues at Rutgers University to mark and honor the seventy-fifth birthday of professor emeritus Eugene E. Agger.

As is almost inevitable in a collection of this kind, the offerings are of uneven merit. Most are clearly written. Several are spirited. But only a few create a lasting impression.

The longest and most likely reference article is by Geoffrey H. Moore, entitled "The Diffusion of Business Cycles." Dipping into the National Bureau's informational stores he presents percentage "diffusion" measures which register the number of industries expanding and contracting. Finding that these indexes lead other measures of aggregate activity, Moore suggests that they ought to "contribute to a proper timing of measures taken to . . . promote recovery" and "they may be helpful in appraising the efficacy of such measures" (p. 58).

In a more provocative piece, on "Rain Making and Monetary Policy," Anatol Murad contends that advocates of monetary controls are indulging in magical dreams. Examining four recent reports he observes that in each case "the writers . . . recognize the failure of monetary policies, yet blandly urge greater reliance upon such policies" (p. 147). Even if his position is overstated, his evidence is of interest.

In a deterministic setting Leopold Kohr ("Economic Systems and Social Size") argues that "if a community is either too small or too large" then "the only possible system is . . . a system of discipline, direction, control. Economically speaking, this means socialism" (p. 208).

A clear position and a fast pace characterize "Colonial Experience and the Social Context of Economic Development Programs," by Harry D. Gideonse. Citing Indonesia, for "its recent history demonstrates so eloquently the hollowness of the usual 'anti-colonial' cant about unilateral exploitation" (p. 250) he attacks the proposition that freedom and advance can be transplanted "by a flow of financial grants matched with a vague desire for material improvement" (p. 257). In contrast Broadus Mitchell ("The Poverty of Economics") holds: "We are at this instant reaping the bitter fruits of imperialism and colonialism." Through free trade, which was merely a "British axiom," other peoples "were repressed . . . into primitive production and lopsided development" (p. 31)

The opening essay is an arid methodological item by Solo on "Economics as Social Philosophy, Moral Philosophy, and Technology," which particularly violates his editorial canons on "significance and clarity." A more lucid note by William C. Bagley, Jr., on "The Task of Institutionalism," chastizes economics for neglecting "culture" though he does not show how the new institutionalism transcends the old. He suggests that theory will disappear when "everyday experience" is studied (p. 21). Occupational unemployment for the theorist is not a new forecast.

Broadus Mitchell thunders in lively scorn and wrath at friend and foe. His range encompasses the classicists, diminishing returns, formal convention papers, academic stock-market forecasters, Keynes in academic gown, Keynes in business suit, Keynes the Judas-goat, politicians, scholarly journals, mathematics, model builders, compensatory finance, full employment, colonialism, etc. He is reassured though that "economics, after all, is not a science but an art . . ." (p. 29). And he reveals that to "turn the gross mass of poverty, ignorance, disease and death into the gold of peace, plenty, and progress" involves "no secret beyond good-will and good judgment" (p. 30).

In a modest statement on "Marketing's Contribution to Economics," R. S. Alexander queries whether a price reduction leaves the demand schedule

unchanged, suggesting that expectational forces may engender a sales decline. These dynamic relations are too frequently ignored. Also, he avers that demand inelasticity (in the neighborhood of accustomed price?) is more common than usually supposed. And he rightly criticizes the extensive preoccupation with a single-product firm.

Sidney I. Simon offers a useful survey of accounting and legal definitions in "Profits, a Semantic Problem Child" and J. Wilner Sundelson, a specialized study of "Forecasting Automotive Sales." Ridgeway Hoegstedt ("Economics and Accounting") wells with pride in reiterating that "accounting is essentially a consensus" of standardized conventions. This he regards as virtue enough. His gentle, scholarly rejoinder to economists is that they "have urged that it [accounting conventions] be replaced by a body of controversy resting on linguistic confusion" (p. 118). His profound, pontifical advice to economists is that "the subject matter of economics is not mechanism, but mankind" (p. 119).

Alexander Balinky covers "Public Finance and the Public Interest," Monroe Berkowitz, with some good insights on the union shop, develops "Public Policy and Union Security," Lawrence Knappen outlines "Managerial Zones of Reasonableness in Public Utility Regulation," and Max Gideonse examines "The Development of International Commodity Policy." Reviewing price stabilization programs, Gideonse decides "that the inherent defects of government control schemes normally outweigh the defects of the free market . . ." (p. 225).

David A. Morse devotes "International Employment Problems and Policy" substantially to the work of UNESCO and the ILO. Kenneth Kurihara follows Harrod's path in a brief coverage of "Growth Theory and the Problem of Economic Stabilization." Robert J. Alexander elaborates mainly some British and Russian history in considering "Who Bears the Cost of Economic Development?" Finally, Roland R. Renne closes with "Land Tenure Reform as an Aspect of Economic Development in Asia." Economic theory today, compared to the older tradition, perhaps pays too little attention to diverse rental methods as an influence on allocational efficiency.

Amid this assortment, and almost in the very middle of it, Milton Friedman has a paper on "The Role of Government in Education," concerned not with the content, nor facilities, nor recruitment of educational personnel but instead with a proposal to separate the financing and administration of education. It is surprising to learn that elementary education is a "nationalized" industry. In Friedman's scheme: "Government could require a minimum level of education which they could finance by giving parents vouchers redeemable for a specified maximum sum per child per year if spent on 'approved' educational services" (p. 127). Doing so, "Government would serve its proper function of improving the operation of the invisible hand without substituting the dead hand of bureaucracy" (p. 144). Though he properly abhors racial segregation, the same anxiety for freedom, this time of those who *choose* segregated schools, enables Friedman to see a saving grace in the plans of some Southern states to abolish the public school system.

University of Pennsylvania

Theorie der allgemeinen Volkswirtschaftspolitik. By HANS-JÜRGEN SERAPHIM. (Goettingen: Vanderhoeck & Ruprecht. 1955. Pp. 351. DM 30.-; cloth DM 33.-.)

The American reader may find the title and the structure of this book somewhat puzzling, if he does not relate them to the typically German approach of the author. For more than a century, German economists have stressed, in their thinking, their research and their teaching, a systematic distinction between the theory of economics and applied economics. They gradually developed the latter into a self-sustaining discipline of economic policy, and in due time they proceeded to divide this new discipline into general and specific parts as well as to bolster it with a theoretical foundation of its own—hence their "theory of general economic policy." It is rather difficult to draw any clear-cut borderline between this theory and the theory of economics. However, decades of professional experience and skillful handling of systemological intricacies have helped the author to overcome some of the obvious difficulties concerned. His efforts have been facilitated by two characteristic attitudes. In a traditionally German way, he explicitly emphasizes the methodological aspects of economic policies and consistently inquires into their sociological background.

Accordingly, the first part of the book is devoted to a reconsideration of relevant old and new methodological debates. The outcome is a series of analytical refinements pertaining to the permissible scope of theoretical abstraction, to the issue of value judgments, to up-to-date model building, and to the bearing of these refinements on the relation between theoretical and applied thinking in the domain of economics. The author's rejection of catallactic economics of the pure exchange-theory pattern as a sufficient foundation of economic policies leads him to an examination of the essential social factors involved.

His sociological appraisal of these factors, which represents the core of his achievement, is concentrated on the phenomenon of economic power as well as on the basic forms of economic organization, respectively treated in the second and third parts of the book. Among the strategic conditions of effective economic power, he successfully analyzes the required personal qualifications and purchasing power, and he adds illuminating remarks on some of the related functional aspects of social structure and economic equilibrium. His morphological comments concerning the basic forms of economic organization reveal the effects upon the market resulting from the development of the tribe, family, medieval feudal and corporate ties, modern private enterprise, class stratification, and economic collectivization. He then makes a stimulating attempt to explain such effects in terms of the historical epochs of economic policies.

The fourth part of the book deals with the subjects, ends, tasks, means and "systems" of economic policies. Most likely, this part could have been profitably expanded even if it were at the expense of the three preceding parts. In particular, it would have been useful to elaborate further on the relationship among the economic categories of "systems," "orders," "proc-

esses," and "fundamentals" determining the over-all goals of economic policy. Nevertheless, it is fair to add that such categories have been abundantly discussed in the economic literature of German-speaking countries; that the author has contributed to the clarification of several relevant penumbrae; and that it would have been beyond the scope of his "general" theory to penetrate specific problems of applied economics.

Possible improvements in the book may be suggested: First, some of the methodological classifications are too rigid. For example, the distinction between economic policy and economic guidance (pp. 326 ff) and the enumeration of seven models reflecting "systems of economic policy" (pp. 334 ff.) should be relaxed and more directly referred to what is usually meant by economic systems. Second, some of the essential theorems should be refocused in order to include more convincing arguments. For instance, the analysis of individual and collective wants (pp. 241 ff.) should be reconsidered in the light of such intermediate cases as relative and absolute social wants, common wants and group wants. The application to economic policies would then be more plausible and efficient. A somewhat similar result could be achieved by reclassifying the five means of economic policy (pp. 300 ff.) and by shifting their emphasis toward empirical differences in the degree of governmental intervention. Third, although it is undoubtedly justifiable to stress the qualitative factors of economic policies, the concomitant quantitative factors and their analysis should also be given adequate attention.

All in all, this book offers a substantial contribution to several neglected chapters of economic methodology and systematology. Especially valuable are its frequent references to the historical development of the doctrines expounded. The author's excellent coverage of recent German economic literature in itself would warrant an English translation.

Syracuse University

Kapitaltheoretische Untersuchungen. By WALTER EUCKEN. 2nd edition, enlarged by 3 essays (Tübingen: J. C. B. Mohr. Zürich: Polygraphischer Verlag. 1954. Pp. xxvii, 336. DM 18.80.)

This volume reprints the *Kapitaltheoretische Untersuchungen* first published by Walter Eucken in 1934. Eucken follows Böhm-Bawerk in basing his interest theory on the productivity and scarcity of capital. In common with the Swedish followers of Böhm-Bawerk, such as Wicksell and Akerman, Eucken frees his analysis from the discount idea that interest reflects a low valuation of future as compared with present goods. He rather stresses the higher productivity of production through time. Interest appears as the payment for the services of capital which permit more time-consuming and therefore more productive processes; it is determined by the general equilibrium of the economy. Böhm-Bawerk toward the end of his *Positive Theory* had already discussed interest in a general equilibrium setting under the simplifying assumptions of only one productive agent and a single product.

Wicksell developed the theory of interest with more than one productive agent and several final products. Eucken considers the production of consumption as well as capital goods and adds the idea that the nature of all inputs changes with a shift in the time period of production.

Though Eucken explicitly recognizes the production of capital goods, he treats the total amount of productive agents as a given constant and thus appears perhaps the last exponent of a "stationary" interest theory. In later essays reprinted as an appendix to the present volume, and in unpublished notes left at the time of his unexpected death in 1950, Eucken attempted to push beyond the limitations of static analysis. Following Hayek, he gave up the idea of an average production period. Under the influence of Keynes, he recognized the role of monetary factors in the determination of the interest rate. Stimulated by his student Lutz—who has contributed a masterly introduction to the new edition—he concerned himself with the structure of interest rates. All this was leading Eucken from static interest analysis toward the search for a more dynamic theory of capital formation and of the economic development which distinguishes succeeding investment periods.

The *Kapitaltheoretische Untersuchungen* may not add much to the main body of economic theory. Yet they stand out as a valiant contribution to rational economic analysis at a time and place given to emotional propaganda rather than rigorous theory. When first published in the Germany of 1934, Eucken visualized his work as the beginning of a new series on "problems of economic theory" and prefaced it by an inquiry on "what does economic theory contribute?" It is this introduction on economic methodology which established Eucken as the great teacher who preserved the tradition of economic reasoning through a decade of totalitarian dictatorship and who prepared his students to help in the re-establishment of a free German economy.

WERNER HOCHWALD

Washington University

Public Policy. A Yearbook of the Graduate School of Public Administration, Harvard University, Volume V. Edited by CARL J. FRIEDRICH and J. KENNETH GALBRAITH. (Cambridge: Graduate School of Public Administration, Harvard University. 1954. Pp. viii, 420. $5.00.)

This book contains a variety of papers without central theme or unifying organization plan. It opens with the text of a lecture by Eugene Meyer, substantially devoted to reminiscences of his diversified experience in the federal service, including the management of prices in World War I, the War Finance Corporation, the Farm Loan Board, the Federal Reserve System, and the Reconstruction Finance Corporation. Part II presents two case studies of antitrust policy, one dealing with the International Business Machines Corporation and the other with the textile machinery industry. Part III contains three papers under the general heading of Planning and Resources Policy: one on watershed flood control, the second on planning research for defense, and the third on the formulation of economic policy in postwar France. Part

IV—Fiscal and Monetary Policy—offers the following assortment: "Monetary-Debt Policy Revisited," "The New Monetary Policy," "Some Aspects of Family Allowances and Income Redistribution in Canada," "The Canadian Exchange Rate," "The Limits of Taxation," and "The Income Tax of France." In Part V are found two papers on Legislation and Parties, one on "Congress and the Fair Deal" and the other on "Party and Separation of Powers."

The usual comment on quality range in such a collection is in order. Contributors include graduate students and senior professors. In appraising a pudding concocted from such mixed ingredients, the reviewer's useful function is to identify the choice plums and hold his peace for the rest.

The most interesting papers are those by Preston on the textile machinery industry, Houghteling on the French income tax, Peret on the limits of taxation, and Musgrave on monetary-debt policy.

Preston's study suggests that the disposition to transfer antitrust policy from a foundation in abusive and predatory practices to a foundation in market power offers an adventure in uncertainty. Since 1920 the textile machinery industry has seen the number of firms producing a full line of cotton preparatory machinery decline from nine to two, the number of loom-makers from five to two. Yet all the normal monopoly tests indicate ambiguous results: in overt restraints on trade, in measures of industrial performance. The intriguing implications of performance in what should be a classic arena for monopolistic manipulation urge the extension of such industry analysis before we are too far committed to the superficially attractive economic concepts as a satisfactory substitute for the traditional legalistic approach to antitrust problems.

Houghteling's study of the French failure to establish effective and equitable income taxes concludes that the root of the difficulty is not a dearth of ideas for reforming the tax structure, but a distribution of political forces that impedes constructive action. In contrast to the tendency in nations with relatively advanced economic development to rely heavily on income taxes, in France income taxes have never produced more than one-fourth of the central government's tax revenues. The aggregative tax burden is heavy, is slightly but irregularly progressive, and is in no sense archaic. The system's principal influence is toward perpetuating characteristics of the French economy that act as drags on economic development. Those with a vested interest in these characteristics are sufficiently powerful to compel policy compromises that fail to convert the tax system into a force for economic progress.

Peret begins with Colin Clark's thesis on the critical limit of taxation. He observes a lack of consistency between the hypothesis of the critical limit and its statistical underpinning. From a review of taxation and economic performance he concludes that taxable capacity is a variable responsive to national resources, their level of utilization, the level of technological development, and the rate of general economic growth. There is no record to support the proposition that the level of taxation in the United States has contributed to either adverse effects in the area of economic development or to inflation.

Musgrave undertakes a reconsideration of the monetary-debt-unemployment-inflation complex with emphasis on removing false issues created by attempting to convert incomplete analysis into policy criteria. This leads him to two conclusions. The first is that monetary-debt and fiscal restrictions are related, not independent, tools, and therefore require resolution within the framework of a general stabilization policy. The second conclusion suggests that the nature of this resolution—the "product mix" of monetary-debt and tax measures—may contribute to important differences in results. These are found in income distribution, in resource allocation, and ultimately in the rate of economic growth.

MELVIN ANSHEN

Carnegie Institute of Technology

Economic History; National Economies; Economic Development

Approaches to Economic Development. By NORMAN S. BUCHANAN and HOWARD S. ELLIS. (New York: Twentieth Century Fund. 1955. Pp. xiv, 494. $5.00.)

Underdeveloped areas are backward in more ways than one. The lack of capital accumulation not only is not the whole story, it is no more prominent that the backwardness of social institutions, cultural attitudes, personal habits and aptitudes, and the bureaucratic inefficiency of governments. A good introductory book on the development of such areas should begin not with growth models and other elaborate machinery, but with the empirical contents of the subject—the characteristics of the people and their institutions, and policy problems expressed in the form in which they present themselves in backward areas. Capital accumulation can be given a central position, but not one that eclipses the less tangible problems.

Ellis and Buchanan have written such a book, and written it well. One pays a price for it; the result is not exciting reading, it is quite untheoretical reading, with no original machinery of analysis and no new program, and often concerned with organizing the obvious. Even the original ideas do not seem original, since they must be on a low level of generality and somewhat mundane in their contents. The result is an excellent text for students but a chore for economists. It is a rewarding chore, but not in intellectual stimulation.

The book could have been somewhat more exciting, and the better for it. Omission of repetitions would have saved space for more advanced sorties; and parts of the book would have been improved by abstract models. Some Malthusian models would have helped the discussion of population; and the treatment of inflation, investment, income growth, and balance of payments could probably have been made more rigorous and less ambiguous without belaboring multipliers excessively. But the purpose of the book is mainly responsible for its lack of climax and stimulation; and the purpose is a proper one.

The scheme is good. Part I, 116 pages, introduces the characteristics of underdeveloped countries, discusses resources and their use in relation to per

capita income, and then gives three chapters of equal weight to capital accumulation, social and cultural factors, and demographic factors. Part II, 115 pages, contains brief histories of the economic developement of England, Japan, France, Germany, and the U.S.S.R., and an historical summary. Part III, 232 pages, is on contemporary problems and policies: development of agriculture, of commerce, of industry; saving, financial institutions, government finance; foreign trade; foreign capital; assistance program for underdeveloped countries; and a chapter on the interests and responsibilities of the United States. For class use Part II could be taken first, last, or where it is, or left out, without disturbing the organization. The reviewer's first inclination was to leave it out, as insufficiently productive of easily transferable policy conclusions; on reflection he is persuaded that its provision of "perspective"—which was the authors' main purpose for it—earns it a firm position somewhere in the book.

The book is least satisfactory where it is most theoretical. The role of capital in production and income generation leans excessively on the concept of factor *proportions* in Chapter 2, and at several points (pp. 42 and 47) seems to confuse income with real wages and to ignore the return on productive assets. For example, "If labor were completely substitutable for land and capital equipment in production, then the dearth of land and capital relative to labor in the underdeveloped areas would make no difference: output per person could be just as high as in the high-income countries" (p. 42). Thus, even though the authors preface their remarks on labor and its productivity with the statement that "unlike land and capital, human beings are at once a factor in production and the end purpose of economic activity," they do not avoid the analytical pitfalls involved. They do, however, avoid a lot of other pitfalls, especially the obstinate one about all differences in labor productivity among countries being due to the quantities of land and capital available; and for their excellent discussion of social, cultural, and personal differences among workers and their productivity they deserve congratulations.

The treatment of inflation is ambiguous. The implicit criterion for fiscal stability seems to be something like constancy of the ratio of money to income (pp. 308, 312, for example) but the implications of this criterion are not carefully handled. There is a hint or two (pp. 308, 312, 388) that noninflationary investment is investment that leads to "an equal flow of marketable product," but this concept has no meaning except in an explicit time-sequence analysis. A number of statements on fiscal stability depend on unstated premises—statements about the comparative inflationary effects of government deficits vs. private deficits (p. 312), commercial bank loans vs. other forms of financing (pp. 307-8), the inflationary effect of capital inflow (pp. 388, 398), and the "income velocity" multiplier (p. 388). With a little thought one can usually provide the particular premise that makes the statement understandable; but the effect on students will be confusion.

Other deficiencies—mentioned here to advise, not to discourage, the user of the book—are: inadequate attention to the exchange rate in discussing the "productivity" criterion for allocation of investment; undue identification of the "productivity" of foreign capital with the specific imports financed by

the foreign exchange (pp. 391-92); similar identification of a country's capacity to service foreign debt with the specific investment projects financed by foreign loans (pp. 394, 398); the absence of systematic discussion of whether the "unseen hand" of the price system and profit motive is, in principle, an ideal allocator of investment, *i.e.*, whether private and social productivity can be identified with each other; insufficient attention to the influence that income distribution objectives will have on the allocation of development among the industries and areas within a country; and a neglect of the critical question of the appropriate rate of capital accumulation (in a time-preference, social stability sense, rather than a fiscal-monetary one) except where the authors use this topic to divide economists rather ruthlessly into two comprehensive schools of thought.

A reviewer can pick faults endlessly from a book that tries to lay an elementary groundwork; the present book has the usual share of deficiencies of a good text, not more. The footnoting is excellent; for people either teaching a course, or briefing themselves on the rudiments of the subject, it supplies a well selected reading list parallel to the text.

As remarked above, the book is not much fun, and probably was not for the authors either, since they had to discipline themselves on nearly every topic. The reviewer, who shares the authors' prejudice on how to approach the subject, thinks the result well worth the labor.

THOMAS C. SCHELLING

Yale University

Economic Development—Principles and Patterns. Edited by HAROLD F. WILLIAMSON and JOHN A. BUTTRICK. (New York: Prentice-Hall. 1954. Pp. xii, 576. $6.75.)

"Underdevelopment" has reached the textbook stage. Since the war, the problems of the less developed countries have occupid a prominent place in economics. Once the great debate about monetary and fiscal policy and about the dollar gap had blown over, no other field in economics, it is probably fair to say, has been so fruitful in new ideas as that of development. Here the discussion is still very much in flux. It is gratifying to think that enough systematic material has accumulated to encourage some bold spirits to write a book addressed chiefly—not exclusively—to college students.

It is not possible, in the framework of this review, to do full justice to all the contributions, but some of the outstanding ones deserve special mention. Harold Williamson opens the book with a thoughtful essay on the meaning and measurement of development. Here the reader finds all the questions, and probably some more, that may have worried him as he contemplates the current developmental scene. J. Spengler contributes an interesting essay that opens up the whole range of population problems. His bold speculations with concrete magnitudes are intriguing, as always. John Buttrick's chapter on capital formation represents, for the analytical point of view, the heart of the book. Nevertheless, I doubt that the casting of familiar propositions into new diagrams, however skillfully done, is of real help to the often broadly

diversified group that meets in development courses, variously known as an interdisciplinary cross-section or motley crew.

Yale Brozen's extremely interesting piece on entrepreneurship and technological change deals with the two analytically and statistically most baffling subjects in the whole field. Here we find the chief discussion in the volume—and only too short—of alternative directions of development. He also suggests methods for stimulating the supply of entrepreneurship, which he regards not so much as a problem of creating the spirit as of removing barriers.

The chapter on cultural factors by Francis L. K. Hsu has much to say that is fascinating to the economist. Hsu sees the source of Western economic pre-eminence in the sense of insecurity that stems from Western individualism. If the various doubts that this theory raises can be resolved, it may have many fruitful implications.

The three closing chapters on individual countries are all excellent. Each demonstrates a different aspect of development. Irene Taeuber, writing on population growth in Japan and Korea, gives the clearest account I have yet seen of the impact of industrialization upon population growth. Helen Lamb describes the immense problems besetting India's economic development. Henry Aubrey analyzes Mexico's rapid growth. Rising inequality of income, allowing a high rate of capital formation, seems to have been an important causal factor.

The book as a whole shows that the field of economic development has not yet shaken down to anything like the well systematized—and somewhat deadening—organization encountered in many other branches of economics. Wide differences of view are to be expected as to what belongs, and where. The present volume has the virtue of a broad-gauged approach, in addition to containing many valuable contributions. On the other hand, it does not deal with any of the general growth theories, nor does it take cognizance of the important current debates, stirred up by the ideas of Prebisch, Singer, Rosenstein-Rodan, and many others. In particular the book is short on policy.

In consequence, it is not easy to tell from the volume exactly where developmental economics stands today—except that it seems to be entering the textbook stage. Some years ago, development theory seemed to be in a phase somewhat analogous to the early stages of Keynesian economics. Much of the theoretical equipment evolved in advanced countries was being rejected as inapplicable to the less developed areas, and, as in the early Keynesian phases, a new economics was being demanded. Some bold and revolutionary ideas came to the fore at that time. Today there seems to be less inclination in development thinking to emphasize the novel and the extreme. There is less of a tendency, for instance, to identify development exclusively with industrialization. The belief in the effectiveness of inflation as a vehicle for development seems to be waning. Perhaps—though this is doubtful—one may discern a somewhat more liberal attitude toward international trade and foreign investment.

It seems also that the pessimism connected with the earlier belief that capital-output ratios for underdeveloped countries were very high, and that very large amounts of capital would be required to achieve a modest degree of development, has yielded to often rather optimistic assumptions. The capital-output ratio as an instrument of developmental thinking and planning has found wide acceptance, sometimes perhaps a little uncritically. The population problem is beginning to be viewed as amenable to policy, and not as subject solely to uncontrollable social and biological forces. Finally, there seems to be less interest in general theories of development and more in detailed analysis of specific problems, though the hope of finding the philosopher's stone of a really universal theory no doubt springs eternal.

Such are the year-to-year issues that are hotly debated for a while and then often laid aside. Of them our volume takes little cognizance. Perhaps that is the part of wisdom in a book that is not intended to be rewitten every two years. It is to the understanding of more permanent problems that the Williamson-Buttrick volume makes its contribution.

HENRY C. WALLICH

Yale University

The Economic Future of Canada. By H. M. H. A. VAN DER VALK. (Toronto and New York: McGraw-Hill. 1954. Pp. 206. $4.75.)

This book was originally written in Dutch by a distinguished Dutch economist in order (as he says in the foreword) ". . . to share a stimulating friendship with [his] own countrymen—many of whom have set out to make their home in a country of which they had only vague impressions." The Canadian edition proceeds to do just this for a much wider readership.

The initial chapters describe the essential characteristics of the Canadian economy in the usual order—the frontier, the population, national income, the resource pattern, industry and transportation. The blossoming growth floodlighted in these early chapters is then analyzed in fuller macro-economic terms—international trade, capital movements, investment and monetary policy. The culminating pages make some broad and perfectly acceptable projections into Canada's economic future.

The descriptive chapters provide an excellent compilation of generally available data in brief, well-organized, and readable style. The analytical section operates within an outline of the Canadian financial institutions, trade structure and public policy. To both parts the European observer brings, at intervals, a fresh awareness of things North Americans sometimes neglect because they are, though extremely important, extremely commonplace. For example: "The European coming to Canada and the U. S. is generally impressed by the large amount of productive work done voluntarily. For this reason the Europeans have a wrong idea about the five-day week. The so-called 'free Saturday' is for many one of the busiest work days of the week, a day of work for themselves" (p. 169).

Constructive criticism can be aimed on two levels. For the uninitiated, "beginner" on Canada, the initial chapters on the frontier and the resource

pattern would have far more meaning if they were projected against a broad framework of the geography and geology of this tremendous region. Moreover, at least to the North American reader, resource development hinges much more emphatically upon public policy both on the national and the provincial level than the European writer perceives. Likewise, a great deal more light could be shed on developing Canadian economic (and broader) policy had there been a clearer statement of the role of the French-Canadian. (Bilingualism is not merely an interesting cultural phenomenon.) One or two points on a lower level undoubtedly reflect the problems encountered in distilling a tremendous subject. Discussing transportation, the author concentrates on the St. Lawrence seaway (with an adequate supply of the by-now familiar diagrams and maps). In effect, a newly groomed tail wags an important dog. Canada's transportation picture is complex. Not least important is the leading role in contemporary expansion played by the country's historic overinvestment in railroads. As a by-product of this, the author may contribute to the impression that Ontario province is an area rich in hydro-electric power. Niagara redevelopment and Ontario's share of St. Lawrence power notwithstanding, power in the future of the eastern region focuses attention on Quebec and Labrador (a sector often eclipsed by the glamor of the Yukon and Northwest Territories' development).

In passing, it may also be difficult for the student of the Canadian economy to accept the relatively minor role given to the United Kingdom's historical position in both financial and entrepreneurial capacities. The modern, independent stature of Canada and the current influx of capital from the United States should not cast a shadow over the real and (even presently) substantial British contribution to the Canadian scene.

Professor van der Valk has made good use of a significant part of the fine array of material now available on Canada and, all things considered, has done very well in condensing encyclopedic information in two hundred pages. Given the present level of ignorance among American college students as to the Canadian economy, the book should find a wider readership than it probably will. To those who do read it, the book's few, well-chosen footnotes will open excellent doors for further reading on Canada.

On the whole, the reviewer feels this is a useful introductory volume on the Canadian economy despite the blemishes undoubtedly induced by the pressure for brevity.

Colgate University

A Report on Monetary Policy in Iraq. By CARL IVERSEN, assisted by P. WINDING and P. N. RASMUSSEN. (Copenhagen: Ejnar Munksgaard Pub. 1954. Pp. 331.)

Professor Iversen joins the growing ranks of Western academicians whose advice has been sought by governments of underdeveloped countries, and gives a highly readable analysis of financial aspects of the development of Iraq. Prepared at behest of National Bank of Iraq, the report is concerned

with monetary policy in its wider sense (*i.e.*, credit, foreign exchange, fiscal, and investment policy).

Iraq, oil-rich, relatively underpopulated, but poverty-stricken, launched a developmental program in 1950 as much from the pressure of expanding oil royalties as from the basic desire of raising living standards. Iversen considers the ideal rate of expansion as one which proceeds as rapidly as consistent with avoidance of inflation and maintenance of adequate exchange reserves; and he analyzes alternative courses of development. The reader is run through a Keynesian gauntlet of autonomous investment, induced effects, one-shot and continuous doses, marginal propensities, closed and open multipliers, accelerators and endogenous cycles. Whether the desired pace is maintained depends further on reaction-time lags, producer expectations, and inventory policies. The way may also be littered with supply bottlenecks (*e.g.*, shortage of skilled manpower and entrepreneurship). If local bottlenecks become generalized, development is retarded and cumulative wage-price inflation threatens. However, the reader is reassured, Iraq enjoys a unique advantage over other underdeveloped areas in its relatively large foreign exchange reserves. This permits it to plan for development without fear of balance-of-payments adversities, and to combat inflation by calling upon foreign supply sources.

Having analyzed the situation of an underdeveloped area exposed to "advanced" ailments, the report considers the applicability of "modern" remedies. Credit policy is hampered by institutional obstacles (*e.g.*, domination of money market by foreign banks and absence of a capital market). Even if these were overcome, Iversen doubts whether credit policy in itself would be effective in containing generalized inflation. Fiscal policy is similarly found lacking. This leaves it up to the Development Board to plan its activities so as to balance approximately available supplies and total demand. Finally, Iversen considers whether Iraq should leave the sterling area in an attempt to preserve the purchasing power of its foreign-exchange assets and concludes that no clear gain would result, unless sterling becomes convertible or Iraq significantly increases its dollar earnings. Since neither possibility seems realistic at present, the country should concentrate on improving its bargaining position within the sterling area.

It may be questioned whether the analytical apparatus employed comes to grips with currently, rather than potentially, relevant problems of underdeveloped areas, and whether sufficient attention has been paid to longer-term institutional adjustments necessary for effectiveness of modern policy prescriptions.

SHELLEY M. MARK

University of Hawaii

Indian Village, By S. C. DUBE, with foreword by M. E. Opler. (Ithaca: Cornell University Press. 1955. Pp. xiv, 248.)

"Instability" in the industrial labor force of underdeveloped countries is assumed to interfere substantially with the effective allocation of human

resources in a country developing its industries. High rates of absenteeism and turnover, low rates of labor productivity, poor work habits, plant indiscipline are all phenomena associated with a work force recently settled in industrial centers. Most students trace the lack of worker "commitment" to the workers' hybrid affiliations, partly industrial and partly agricultural, to the "village nexus." It is argued that new industrial workers are often unable so sever the umbilical cord that ties them to the village. As industrial workers they appear motivated by the mores of the village rather than those of the city. They are "in the city but not of the city."

Study of the socio-economic structure of villages in underdeveloped countries has a place in the study of economic development even if one rejects the "village nexus" hypothesis. After all, the majority of the economically active population of most underdeveloped countries is to be found in villages. It is there that underemployment and unemployment is most marked and it is in the villages that economic and social growth is to make its greatest strides.

Dube's *Indian Village* provides the student of economic growth in underdeveloped countries with an excellent base line study of the social and economic life of a villager.

Shamirpet is a village of less than 3,000 people located about twenty-five miles from Hyderabad, in South India. Although the author claims no particular typicalness for it, Shamirpet possesses characteristics common to most rural communities in India. In its economic constitution Shamirpet shows features present in the villages of most predominantly agricultural countries. All aspects of village life are surveyed to ascertain to what extent social, economic and political changes currently taking place in India and the world are affecting it. Changes in the role of the family, the caste, the village council are reported with clarity and in language void of narrow professional jargon. Much emphasis is placed on the nature and change of ritual and on the web of family ties; yet at least 105 pages of the 235 pages of the text deal directly with the economic structure of the village.

Dube provides the reader with an occupational breakdown of the total population. The dependence of the great majority of the population on the productive activities of the few (only 336 people find full-time employment and produce the food consumed by the village); the extremely small number of people engaged in activities not connected with agriculture (only 331 persons find occasion to work in areas other than agriculture and of these 90 are government servants); and the very high level of underemployment—all characteristic of the economy of underdeveloped countries—come vividly to the reader's attention.

Land distribution as well as that of other assets is discussed. So are the complex exchange relationships which show the carry-over of traditional division of labor and the role of caste.

Shamirpet is no isolated center of the hinterland, being connected to the capital by no less than 12 busses which go through the village every day. Nor is the village economically independent: "the economy of the village is only partially self-sufficient" (p. 87). Consumers and producers goods (the weavers' spindles) are imported from the nearby capital. Labor is exported

in the trickle of workers that bicycle to the capital to look for employment as often as to go to work. Precisely in the analysis of the village dependence on the rest of the world lies the book's importance. Dube notes that: "For over a century 'the timeless and changeless Indian Village' has been the ideal of the romanticist" (p. 212).

Changes that had been in the making in the last seventy-five or a hundred years and which became more marked after 1948 are looked at in detail. Although much concerned in social changes the author finds that most are traceable to changes in the "material culture and technology" and argues from the readiness in accepting earlier changes that "it is justifiable to predict that given suitable conditions the tempo of change would greatly increase" (p. 235).

The economic situation of present-day India whose rapid economic development has surprised many Indian and Western economists is made to hinge on the rapid "spreading of the market." For an understanding of the phenomenon, in real terms, *Indian Village* is a must for the student of economic development.

Statistics and Econometrics

Linear Aggregation of Economic Relations. By H. THEIL. Contributions to Econ. Analysis VII. (Amsterdam: North-Holland Publishing Company. 1954. Pp. xi, 205. $5.00.)

Aggregation theory is concerned with the relations between microtheory, macrotheory and aggregation procedures. Such procedures are constructed as definitions of macrovariables in the form of functions of a specified group of microvariables. Earlier studies in this field by Klein, Shou-Shan-Pu, and May established and discussed three distinct problems: (a) to determine aggregation procedures consistent with a postulated micro- and macrotheory; (b) to specify a macrotheory consistent with a postulated microtheory and postulated aggregation procedure; (c) to determine a class of microtheories consistent with a postulated macrotheory and specified aggregation procedure. For quite a number of years aggregation theory was neglected even as a few contributions were made on special topics in input-output analysis. The present book by a Dutch econometrician revives the discussion. It should be emphasized that a further investigation of the problems in the field is certainly required, *e.g.*, existing macrotheory contains relations between macrovariables which are inconsistent with generally accepted measurement procedures of the variables involved. Such a further investigation is contained in this book, and let it be immediately stated that it is a well organized and clearly executed analysis. The author restricts his problem in two general directions: (a) he considers essentially linear models and linear aggregation, *i.e.*, the case where macrovariables appear as linear forms of microvariables, and (b) by the particular choice of procedure for deriving relations between the micro- and macrostructure of a given class of phenomena. This procedure

may be termed "statistical" to distinguish it from another possible approach. The various chapters of the book unfold the logic of the chosen procedure in a series of cases with rising degree of complexity.

After a general introduction the author discusses in three subsequent chapters three types of aggregation: aggregation over individuals, over commodities and over time. The theorems obtained indicate a close connection between the formal structure of the three types of aggregation. The essential features of Theil's analysis in these chapters can be summarized in the following way: Suppose there is postulated a set of microrelations connecting microvariables y_i with microvariables x_{jh}. Aggregation procedures are postulated: macrovariable Y is the sum (weighted or not) of the y_i and each X_j is the sum of the corresponding x_{jh} (with respect to h). Then it is postulated that the macrovariables are connected by a relation similar in form to the corresponding microrelations. The problem now is to determine relations between the parameters of the micro- and the macrostructure. For this purpose a new set of auxiliary relations is introduced, defining each of the microvariables x_{jh} as a function of all the macrovariables X_i. These relations have no economic meaning; they are introduced for "purely statistical" considerations. As a result of various substitutions and rearrangements we derive then the intercept-macroparameter as a sum of two components; the first component is the sum of the intercept-microparameters, and the second component is a multiple of the covariance between the intercept-parameters of the auxiliary regression and the slope microparameters. We obtain similarly the slope macroparameters as a sum of the average value of corresponding slope microparameters plus a term indicating a covariance adjustment, depending on the covariance between the slope-parameters of the auxiliary regression and the slope microparameters. Some important conclusions follow from this result. In general a macroparameter will depend on all the microparameters. Thus, a small macroparameter does not necessarily mean that the corresponding microparameters are small. A serious consequence of the "covariance adjustment" in the relation between micro- and macroparameters is the possibility of contradictions between micro- and macrotheories, *i.e.*, that the reaction patterns in endogenous variables relative to given changes in exogenous variables will differ in the two schemes. Further, due to the derivation by means of the auxiliary regression, the "covariance adjustment" depends on the observed values of the microvariables. This implies that the macroparameters may change in the course of time even within a constant environment of microparameters. And as long as the "covariance adjustment" does not vanish, the estimates of macroparamenters will depend on the statistical methods chosen. Considering these troublesome results it is therefore interesting to note that there exist aggregation procedures in the form of fixed-weight sums of microvariables which will eliminate the covariance adjustment. Consequently, for suitably chosen macrovariables, we find that the intercept macroparameter is just the sum of the corresponding microintercepts and the slope macroparameter just an average of corresponding slope microparameters. In Chapter 5 the author turns to a discussion of aggregating a *system* of microrelations into a *system* of macrorelations. Some of the techniques developed by the Cowles

Commission are used in the context, and this then permits an application of previously established results to this case. Given are again a microsystem, aggregation of micro- into macrovariables, and a macrosystem in a form similar to the microsystem. In a first step the reduced forms of the micro- and macrosystem are obtained. Previously established theorems can be immediately applied to these sets of reduced forms so that the parameters of the macroreduced forms become expressible in terms of sums of corresponding microreduced form parameters and some covariance adjustment. This makes the parameters of the macroreduced form dependent on the microstructure, and provided that the macrostructure is identifiable, the same property holds for every parameter of the macrosystem. Chapter 6 extends the results to a changing economy, *i.e.*, an economy with a changing number of individuals, commodities and changing microparameters. By means of a division into subperiods and an additional auxiliary relation involving the averages of the microvariables in each subperiod the former results can easily be extended, and the macrointercept and macroslope parameter appear as sums of weighted averages of certain other parameters. By a suitable choice of weighted aggregation the most troublesome features of aggregating within a changing microenvironment can be eliminated. Chapter 7 is devoted to an investigation of "perfect aggregation," which is defined in terms of absence of contradiction between micro- and macrosystems. Perfect aggregation prevails if the aggregation bias defined in terms of the covariance adjustments vanishes. There always exists a suitable choice of linear aggregation functions which will assure perfect aggregation. A concluding chapter summarizes the results and considers the relevance of aggregation analysis.

This compactly and clearly written book which exhibits a high degree of econometric craftsmanship does not clearly answer one basic question for the reader. If in any given situation, microsystem, aggregation functions and macrosystem are given, then as a result of manipulating linear systems we obtain solutions for macroparameters in terms of corresponding microparameters only. Consistency requires that these relations be satisfied. But the author uses a different approach, by means of the auxiliary regression. Thus, a more explicit justification of his procedure in terms of the auxiliary functions would provide additional information to the reader.

KARL BRUNNER

University of California, Los Angeles

Einführung in die Theorie der Zentralverwaltungswirtschaft. By K. PAUL HENSEL. Schriften zum Vergleich wirtschaftlicher Lenkungssysteme. (Stuttgart: Gustav Fischer. 1954. Pp. viii, 234. DM 11.50.)

Hensel's study is a first major advance in the theoretical exploration of the planning mechanism of a centrally administered economy since the controversy initiated by O. Neurath, von Mises and Max Weber got sidetracked in various attempts to calculate the prices of productive factors by means of Walras' and Cassel's systems of equations and O. Lange's later elaboration of a theoretical model of "competitive socialism." Unlike these earlier attempts at a solution of the problem of economic calculation Hensel is always conscious

of the fact that different economic systems must be understood as different forms of economic organization which have their own specific techniques and procedures for the determination of the relative importance of aims and means and hence call for different theoretical models for the analysis and interpretation of the manner in which the problems of allocation and over-all coordination of the parts into a whole find a solution.

In full recognition of the difficulties involved in any quantitative calculation *in natura* (*Naturalrechnung*) and in full command of the familiar general conceptual framework which permits us to view economic reality in terms of its technical and economic interdependence, Hensel develops a theoretical model of the planning mechanism by drawing, like Eucken before him, upon the experiences of the German war economy. But unlike Eucken he considers the problems of central economic planning as basically solvable. The model is based upon many carefully drawn distinctions the most fruitful of which is probably that between the elaboration of the plans for the various economic units, their coordination into a centrally equilibrated over-all plan, and the actual execution of the plan as well as its effective control by a central planning authority.

Whereas the execution of the plan and its control are based upon accounting prices and upon calculations in monetary units, the elaboration of the individual plans and their coordination into a central over-all plan takes place in terms of a calculation in kind, which Hensel shows is the only possible and completely adequate form of economic calculation. After having chosen the length of the planning period and having tentatively determined the requirements of direct goods in accordance with norms of consumption and the social preference scales of the central planning authority, the major task of the planning authority consists in the preparation of preliminary quantitative balances (*Mengenbilanzen*) which list the as yet tentative requirements opposite the available supplies and planned output of goods of all degrees of intermediacy. The next step is concerned with the translation of consumers goods into intermediate goods (including land and labor) by means of technical coefficients which express the technical input-output relations prevailing at the time. These technical coefficients enable the central planning authority to translate all quantitative plans for direct goods into as many quantitative balances of supplies and requirements as there are intermediate goods; in this manner it is possible to bring into the open the relative over-all scarcities of all goods in the form of deficits (or surpluses).

The totality of these quantitative balances and their respective deficits not only show the technical interdependence as well as the competing character and complementarity of all ends and means but bring to light the critical shortages of original factors of production (bottlenecks). As such these balances are the prerequisites for the final establishment of (partial) *equilibria* of all individual plans by either reducing requirements or increasing output. This adjustment in the form of an equalization of planned output and requirement can take place only in the light of a final review of the original tentative determination of the relative importance of different aims whose competing character has been made visible in the light of the technical inter-

dependence and the complementarity of all aims and means revealed by the deficits of the quantitative balances. This final decision within the planning authority takes necessarily the form of a weighing of the relative marginal importance of different objectives which must be sacrificed (or are to be attained) as a result of the necessary substitution of scarce intermediate goods (ultimately the original factors labor and land) from one use in an alternative one. Once this decision has been reached the adjustment of the quantitative balances is complete, the coordination of all individual plans (for each group of commodities and factors) emerges automatically; the position of a "general planning equilibrium" is attained; a central over-all plan has been established.

The important point is that the coordination and adjustment of the individual plans is solved beforehand within the central planning authority. The maximizing of "utility" takes place in the light of objectives of the authority. Hensel does not devote major attention to the question of the relationship between these objectives and those of individual households; however, he seems to imply that any adjustment of the plan to the wishes of individual households is incompatible (*systemfremd*) with the nature of a centrally administered economy. Inferences drawn from empirical data derived from centrally administered economies engaged in production for war and defense or for that matter rapid expansion of heavy capital goods industries may color our conclusions just as much as categories and generalizations applicable to one form of economic organization may mislead us. After all, the technical difficulties of establishing the preferences of individual households, for instance by public opinion polls, are much less formidable than the calculation of the technical coefficients involved in Hensel's translation of consumers goods into goods of different degrees of intermediacy.

It is not possible to develop this necessarily incomplete outline of the core of Hensel's positive solution in greater detail. Suffice it to add that the book concludes with a comprehensive analysis of the problem of price formation and the role of monetary calculation, both of which play an important role not in the drawing up of the plan but in connection with the effective control of its execution—particularly in connection with the central finance plan and the related function of banks as central control agencies and the establishment of various types of incentives related to the reduction of money outlays in individual production units, the avoidance of social costs (diseconomies) and the mobilization of labor in accordance with the directives of the plan.

A final part contains a useful comparative survey of the role and the method of economic calculation under conditions of decentralized market economies and centrally administered economic systems as well as a short section devoted to a penetrating survey of the evolution of the theory of economic calculation since Neurath advocated a calculation *in natura* during the second decade of the century.

The whole study is a vivid demonstration of what comparative economic analysis in terms of ideal types and models can achieve if it stays close to the nature of the case and if it steers clear of the danger of utilizing uncritically modes of thinking adequate for the analysis of one kind of economic order as well as normative prejudgments of all kinds which have nothing to

do with the problem at hand. The author's theoretical solution of the problem of economic calculation will receive valuable support in practice by the current work in the field of input-output analysis of which Hensel was apparently not aware.

K. WILLIAM KAPP

Brooklyn College

Business Fluctuations; Prices

Regularization of Business Investment. A Conference of the Universities-National Bureau Committee for Economic Research. Edited by MELVIN DE CHAZEAU. (Princeton: Princeton University Press. 1954. Pp. xxvi, 513. $8.00.)

The present volume makes available the papers and comments presented at a two-day conference sponsored by the Universities-National Bureau Committee for Economic Research to explore what contribution private business firms might make, in their own self-interest and without collusion, to our national economic goals of sustaining high levels of income and productive employment. The conference grew out of the concern of the members of the planning committee that in the historical context of the Great Depression, the war and the fears of the postwar years, economists and the public generally had perhaps been so preoccupied with the primary responsibilities of the government for stabilizing business conditions that inadequate consideration had been given to the potential contributions private business itself might make to this objective. That something worthwhile might be accomplished outside of government along these lines was suggested by the progress business had already made in reducing seasonal instability in production and employment and by the increasingly broad and constructive view many businessmen were known to be taking of their management responsibilities. But little serious consideration, either in academic or business circles, had been given to the question of just what responsibility private enterprise could prudently accept and reasonably be expected to discharge for reducing the severity of the cyclical declines in employment and business volume. Any possible contributions of business itself to reducing cyclical instability would further reduce the basis for some of the most serious indictments of the system. There was also some feeling in the committee that to the extent feasible, such action by business itself might be needed to reduce the dependence on government action which, while promoting sustained high levels of income, might weaken our private enterprise system.[1]

The conference brought together an impressive group of academic and business economists. Viewed as a whole, the volume provides much the best informed, broadly based and penetrating analysis of this subject matter so far available. While it is inevitable that not all of the papers come up to the high standards characterizing the volume as a whole, even the thinner papers provide fresh material that must be reckoned with. Every serious student of the

[1] The introduction to the volume makes the point that "professional literature is replete with analyses of and recommendations for government action and policy, but too little attention has been given to the impact of such proposals on the functioning, let alone the strengthening, of our private enterprise system" (p. xv).

business cycle and of stabilization policy for many years to come will need to be familiar with the papers in this volume. This is true as much for the issues left unresolved and for the suggestions of gaps in our knowledge and needs for further research, as for the important positive contributions made in the papers. In this connection, special attention should be given to the editor's introduction and the excellent "appraisals" of the conference by Don Woodward, Adolph Abramson and Ruth Mack in the final section.

Because of the broad range of material and analysis involved in the central issues of the conference and the generally high quality of the individual papers, the volume will also be a valuable reference for a much broader audience than would be primarily concerned with the specific problem of stabilization policy. The numerous insights provided concerning the way in which business decisions regarding investment outlays are made, and concerning the character and impact of important noneconomic and organizational factors bearing on these decisions are particularly valuable. Melvin de Chazeau's paper, which summarizes the materials gathered in his extensive field work on the investment policies and decision-making of some 45 leading companies under the auspices of the Committee for Economic Development, is outstanding in this respect, as well as in its wise and judicious analysis of the broader subject of the conference. In the words of one of the discussants from business, this paper "reflects a familiarity with the meanings, process, and functions of the modern business concern and the private enterprise system that would be remarkable for an academic economist even if it were not as rare as it unfortunately is." This paper will surely rank with the studies of investment behavior by Ruth Mack, George Terborgh, Walter Heller, and Michael Gort, for economists concerned with corporate investment policy and industrial organization. Kent T. Healy's paper on capital investment in railroads is also especially valuable for its combination of new material, careful analysis and a rich insight into the actual decision-making processes involved. Within the framework of more orthodox considerations and therapy, Joel Dean provides a broad and penetrating analysis of the financial implications for the firm of shifts in the timing of its investments.

The volume also provides important material concerning the effects of flows of funds upon the volume of investment, and the possibility of regularizing investment through changes in the financial policies of both business firms and private financial institutions. The generally excellent discussion of these matters in the paper of Jacoby and Weston is somewhat weakened however by failure to allow for the increases in funds from operations which business firms would have enjoyed had investment expenditures in fact been stabilized, as they assume in the rest of their calculations. Albert G. Hart gives a brief but highly suggestive list of government measures to promote regularization in private investment and B. H. Higgins reviews the efforts made along these lines in other countries. Brozen takes up the impact of technological change on the time pattern of business investment along with policies to stabilize investment in the face of erratic technological development. Abramovitz points up the implications of his research into business inventory policies on the stabilization problem in stimulating fashion and Millard Hastay provides a good

brief summary of the National Bureau's research of the cyclical behavior of investment outlays. Economists interested in any of these related problems as well as those concerned with the primary issue posed for the conference itself cannot afford to overlook the valuable material and analysis in this volume.

JOHN LINTNER

Harvard University

The Great Crash, 1929. By JOHN KENNETH GALBRAITH. (Boston: Houghton Mifflin Co. 1955. Pp. ix, 212. $3.00.)

In this little book Galbraith boldly enters Error's den to do battle with one of her more innocent looking, but actually very dangerous, offspring, Complacency about a Speculative Boom in Stock Prices. Doubts about the reality of this particular beast should have been dispelled by the reaction to the Fulbright Committee hearings last March. Then, as in the 'twenties, the mere suggestion that stock prices might be going up too fast was treated as nonsense, or perhaps something even worse, both by the speculators themselves and by those leaders of business and government who confuse the prosperity of stock-market speculators with the prosperity of the whole economy. We must be profoundly grateful to Galbraith, Eccles, and the others who spoke out clearly and courageously about the dangers of the developing boom.

The Great Crash amplifies and reinforces Galbraith's testimony before the Fulbright Committee. His primary purpose, he tells us, is to recount the story of the great stock market boom of the late 'twenties and the crash which followed. This he does in a way to bring out the full drama and color of that most dramatic and colorful episode. In telling the story he also effectively points the moral: first, a boom once it has come to feed upon itself, *i.e.*, once the rise in prices has come to depend on the expectation of a further rise, is inherently unstable; and, second, a major break in the stock market is bound to have serious repercussions on business activity in general. The book is so well written and its lesson is so clearly developed that the chances are excellent it will justify the hope which its author expresses in the opening chapter:

> Since 1929 we have enacted numerous laws designed to make securities speculation more honest and, it is hoped, more readily restrained. None of these is a perfect safeguard. The signal feature of the mass escape from reality that occurred in 1929 and before—and which has characterized every previous speculative outburst from the South Sea Bubble to the Florida land boom—was that it carried Authority with it. Governments were either bemused as were the speculators or they deemed it unwise to be sane. . . . The wonder, indeed, is that since 1929 we have been spared so long. One reason, without doubt, is that the experience of 1929 burned itself so deeply into the national consciousness. It is worth hoping that a history such as this will keep bright that immunizing memory for a little longer.

The book's only weakness is in a very real sense a product of its great strength. The author becomes so absorbed in the fight with his chosen antagonist that he allows another of Error's brood, Oversimplification of Economic Processes, to escape practically unscathed.

Until the middle of the nineteen thirties depressions were generally explained in one of three ways: as part of a natural and inevitable rhythm in economic activity, as the product of stupidity and mismanagement on the part of foreigners, as the result of the collapse of a boom in stocks or real estate. In the early years of the Great Depression, Republicans generally favored the first two explanations, Democrats the third. Neither found its diagnosis of much use in devising measures to stimulate recovery. Republicans put their faith in time and the tariff, Democrats in the S.E.C. and other financial reforms. Both felt bewildered and frustrated by the ineffectiveness of these remedies.

The Democrats did, of course, try other things too, some of which turned out to be much more useful in helping to get us out of the depression. But their approach was largely a hit-or-miss sort of thing and many of them were never clear as to which measures had contributed to recovery and which had not.

We have learned a great deal in the last twenty years, thanks to the work of Keynes, Hansen, Currie, Samuelson, and others, about the causes of both depression and recovery. Galbraith refers to some of this work in his last two chapters. But the references are too brief to mean much to readers who are not already familiar with modern income and employment theory. For instance, many economists think that the leveling off of consumer demand in the late 'twenties for such major products as automobiles and houses was, through its effect on investment, quite as important a cause of the depression as the collapse of the stock-market boom. Galbraith's only reference to this phenomenon is in a footnote (p. 181)—scarcely enough to make much impression on the uninitiated reader. Most readers will, I am afraid, come away from this book with no greater understanding of what causes depressions than they might have had in 1929, or 1893, or 1837. Their overwhelming impression will be that depressions are, as the history books say, the result of "excessive" or "wild" speculation in stocks, or railroad building, or Western lands. An important element of the truth, no doubt, and one that should be re-emphasized for each succeeding generation, but scarcely the whole truth.

It is perhaps illegitimate to complain because the author of a thoroughly good book has not written another and even better book. I cannot help regretting, however, that while he was striking such a telling blow for economic sanity Galbraith let slip the opportunity to strike a blow also for economic sophistication.

ALAN SWEEZY

California Institute of Technology

Economic Fluctuations. By MAURICE W. LEE. (Homewood, Ill.: Richard D. Irwin. 1955. Pp. xviii, 633. $6.00.)

Economic Fluctuations is designed for a one-semester course for either liberal arts or business administration undergraduates. It does not presuppose too much training in economic analysis, other than what might be supplied by an adequate introductory course. Its subject matter is sufficiently varied, yet with simplified descriptions, so that it can be understood by the newcomer and also be of interest to the concentrator.

The sections cover (in the following order) the nature of economic fluctua-

tions; the history of economic fluctuations in the United States; the nature and use of the national income accounts; business cycle theories; economic stabilization; forecasting; and international economic stabilization. The stabilization chapters also include the problems of a war (or siege) economy, and a recognition that such circumstances are no longer unique events. This reader in particular was pleased to see the international aspects treated as a major part, rather than as an addendum to the theoretical section. The author is also to be commended for his frequent cautions on the gap between theory and its application and the complexities involved in any policy implementation.

For the instructor relying on this text the end of each chapter contains many good essay questions, although some would be difficult to answer without the material contained in subsequent sections.

Quite a bit of space is allocated to the Keynesian concepts, and an excellent summary discusses the instability of the consumption function. In fact, most of the major concepts associated with macroeconomics are treated quite well. Unfortunately, their integration into a coherent theory is not as successful; it is doubtful if the average student will grasp the process fully without further explanation by the instructor. The author could also improve his exposition of the equality of savings and investment.

There are other defects, some of which can be remedied quite easily by anyone selecting the book, but others would require revision in a new edition. The major structural deficiency is the placing of the historical before the theoretical sections. It would be difficult to have much of a classroom discussion of the former without first having available some analytical aids. For example, the open market operations of the '20's are discussed on page 206, but their influence on the banking system and the economy in general is not explained until pages 458-59. Similarly, the historical section has frequent references to fiscal policy, well before its cyclical effects are covered.

Although most of the theoretical summarization is satisfactory, two areas in particular could be improved: those concerned with Wicksell and the natural rate of interest, and liquidity preference. The latter should certainly be expanded, in view of its crucial role. Greater space could also be given to suppressed inflation and its control.

The book also suffers from minor lapses and errors which can easily be remedied. For example, page 392 refers to a nonexistent accompanying chart; page 478 refers to a table containing both long- and short-term rates, but only the former are given; while a reference to Fisher on page 327 could not be found.

Regrettable, too, is the repetitiveness at times of the style. Occasionally a short explanation is followed by a summary practically repeating the idea almost word for word. Or sloppy phrasing leaves the reader in doubt as to just what is meant; to illustrate, on page 486 the student would be puzzled whether the increase in the public's holding of the government debt meant the public, as stated, or the commercial banks, as is meant. Similarly, the anecdote (p. 84, fn. 1) will be lost unless it is realized that reference is being made to a least-squares curve.

However, these defects actually are merely annoying, for the text is other-

wise very acceptable. The general tone is eclectic and cautious, a quality of the book with which this reviewer is most sympathetic. The theoretical material is summarized compactly, avoiding the excessive length that make compendia of so many works. The historical and factual discussions are generally quite clear, so that the cause and effects can be readily followed, especially since the author provides so many charts and short tables. These can also serve for classroom problems, since enough are supplied to allow for divergent interpretations and policy recommendations. For this alone the busy instructor should be thankful.

Money and Banking; Short-Term Credit; Consumer Finance

Quelques enseignements de l'évolution monétaire française de 1948 à 1952. By PIERRE DIETERLEN. Centre d'Études Economiques. Études et Memoires No. 19. (Paris: Librairie Armand Colin. 1954. Pp. 232. Fr. 750.)

In seeking the lessons of France's monetary developments from 1948 to 1952, Mr. Dieterlen has done a very valuable piece of research. He reviews, in the first part of the book, the theoretical prolegomena, which he exposes, however, not as a self-contained body of doctrine but rather as a framework within which he discusses, in the second part, the various phases and aspects of France's monetary developments, and, in the third part, its monetary policy. Throughout the book, he seeks in France's monetary experience the fundamental lessons and their implications for monetary policy today.

The gist of the author's observations is that, during recent years, inflation in France was attributable not so much to the government deficit, the rise in wages, and the continued large volume of fixed investment, as to speculative and precautionary motives that prompted businessmen to exploit adroitly all of these phenomena by shifting from cash into nonmoney assets—and by borrowing to acquire such assets—in anticipation of market conditions, price movements, etc. Such moves by businessmen could not always be effectively countered by monetary policy alone. In Dieterlen's opinion, the credit controls adopted in France prevented a hyperinflation at the time of their establishment in 1948 and again in 1951, but were unable to prevent, after the Korean outbreak, a greater degree of inflation in France than in other European countries—largely because of the "safety valves" that rendered these controls partially ineffective, since both the government and business, each for reasons of its own, were reluctant to accept more stringent restraint. The crucial importance of speculative and precautionary motives as the inflationary factor in contemporary France is also attested, but in a negative way, by developments in 1952 and 1953: as business sentiment and expectations became at that time less "speculative," even the combination of a persistent government deficit financed to a large extent by recourse to the banking system, of political uncertainty, of social unrest, and of course, of easy money, failed to give rise to any inflationary strains.

Institutional, political, and psychosociological forces must undoubtedly be taken into account in any realistic study of inflation in the contemporary world. Dieterlen's effort to enliven abstract economic analysis and the interpretation of monetary data with continuing reference to the "real" world is therefore to be welcomed. Yet I wonder whether, in discussing the inherent limitations on monetary policy in France, he does not take too much for granted. True enough, for reasons that are well known, monetary and fiscal policies in France are not complementary; in effect, monetary policy, in addition to its proper tasks, has also the task of offsetting the inadequacies of fiscal policy. Nevertheless, while recognizing the tremendous difficulties of monetary policy in France, the question may well be raised whether creeping inflation, however tempered it may be by periodic pauses, is as inevitable as Dieterlen seems to imply. Exception should, I believe, also be taken to some of his interpretive comments. For instance, he regards quantitative credit controls as something different from discount and open-market policy, thus confining such controls to rediscount ceilings and primary and secondary commercial-bank reserve requirements and their variations—as if discount and open-market policies were not quantitative credit control instruments par excellence. Furthermore, he seems to have somewhat greater confidence in qualitative credit controls, unaided by general monetary restraint, than appears warranted in the light of the postwar experience. Finally, his scepticism about the effects of interest rate fluctuations, even though seemingly corroborated by recent developments in France, appears unduly generalized.

Altogether, Dieterlen's book is a very valuable contribution to the recent literature on money. His theoretical framework is not only well presented, but also refreshingly full of new insights; his statistical analysis ingenious; and his discussion of policy problems illuminating. It is a most helpful book, which deserves to be studied carefully not only by those interested in France, but by anyone who wishes to keep abreast of current thinking in the field of money and banking.

M. A. Kriz

New York, N.Y.

Trends in Consumer Finance. By M. R. Neifeld. (Easton, Pa.: Mack Publishing Co. 1954. Pp. xiv, 142. $6.00.)

M. R. Neifeld's "Trends in Consumer Finance" is a comprehensive study of small loan companies, whose lending operations account for about 6 per cent of total consumer credit outstanding. The title of the book is somewhat misleading since the term "consumer finance" normally refers to the broader scope of consumer savings and credit.

Neifeld traces the development of small loan companies in the United States under the Uniform Small Loan Law. He discusses volume of loans made, repayments, receivables, charge-offs, expenses including advertising, interest charges and earnings, capitalization, and profits. Neifeld presents a typical small loan company, shows its "break-even" size and the loan-mix by size of loans. The book also covers the characteristics of small loan company borrow-

ers, the reasons for borrowing, and the security used for loans. These facts are presented in tabular and graphical form, many from 1938 through 1952, on both a national and state-by-state basis. Much of this statistical information was not available heretofore. Special compilations were prepared by state banking officials at Neifeld's request and numerous gaps were filled by careful estimating on the author's part.

This book makes a real contribution to our statistical knowledge of small loan companies and the role they play in today's society. It should serve as a valuable source of information for anyone interested in consumer lending.

DUNCAN McC. HOLTHAUSEN

Tenafly, N.J.

Money, Banking and the Financial System. By MILTON L. STOKES and CARL T. ARLT. (New York: Ronald Press. 1955. Pp. vi, 670. $6.00.)

The increasingly troublesome "book surplus" problem places a heavy responsibility on the writers of any new text, especially in the field of money and banking, to justify their action by making explicit the nature of the contribution they feel they are making to the cause of education.

In the case of the book now under review the authors maintain, quite rightly, that the chief handicap of the student of money and banking "is a tendency to forget the central theme of the subject, namely the role of money and financial institutions in the determination and fluctuation of price and income levels." Such students, they say further, "need an explicit frame of reference for understanding and relating the various aspects of an admittedly complex subject." This "frame of reference" is provided most adequately by the first four chapters of the book which give a very lucid discussion of monetary theory designed especially to "show the strategic importance of the flow of money expenditures as a determinant of price levels, income, and output." This inherently difficult material is presented in terms that should be readily grasped by any student who has had a minimum of an elementary course in economics.

This introductory section, which comprises about 15 per cent of the entire book, is followed by chapters of a more descriptive nature that cover all the topics traditionally taught in a course in money and banking. The teacher of the subject will be particularly interested in the arrangement of this material designed to make the book more flexible in use. It could very well be used for a one-semester course by omitting the sections on international economics and trade, on money markets, and the financing of investment and consumer expenditures. These topics are very often taught in separate courses anyway. On the other hand, by dealing with certain sections more intensively and by providing a moderate amount of outside reading, the text could well serve the needs of a full-year course.

For those who still believe that a student will gain a better understanding of today's problems through a study of the evolutionary development of our monetary and banking institutions, there are several good but somewhat brief historical chapters. The two on the development of monetary standards in the United States and the three on the historical development of commercial and

central banking provide a background and perspective which should make for a more intelligent study of the material that follows.

The practice of introducing certain "panoramic" chapters giving a broad outline of the subject and following these with other chapters presenting the more detailed analysis and description should enable the student to orient himself better and make his reading more fruitful.

The book is written in an easy flowing and, in spite of its dual authorship, even style which should make an especial appeal to the undergraduate student. There is a nice balance maintained between theoretical analysis and the mechanics of operation of the various institutions treated.

Business Finance; Investments and Security Markets; Insurance

Investment Principles and Policy. By RALPH R. PICKETT and MARSHALL D. KETCHUM. (New York: Harper and Brothers. 1954. Pp. ix, 820. $6.00.)

This textbook is intended for college students and for investors interested in acquiring a knowledge of the basic principles of investment. The volume is well written, comprehensive in coverage, and it constitutes a useful addition to the other existing textbooks in a field that is once again receiving increasing attention by both college students and the public at large. Economists, in particular, will be gratified by the sophisticated treatment given to the study of business fluctuations and to the forecasting of business trends.

The usefulness of the book, however, is limited by the decision of the authors to refrain from discussing investments from the viewpoint of the institutional investor as distinguished from the individual investor. This is a defect not only because a substantial part of the professional students of investments are likely to find employment with the investment departments of life insurance companies, pension funds, mutual funds, etc., but especially because the operations of these institutional investors have a profound effect on the behavior of the securities markets. This was brought out emphatically at the recent hearings before the Senate Committee on Banking and Currency on the stock market which constitute an essential supplement to all existing textbooks on the subject. This omission is all the more regrettable because the book is of inordinate length. Such length is hardly necessary in a field in which the daily financial section of the newspapers, annual reports of corporations, and a flood of releases by investment houses are readily available as supplementary sources of information.

In its discussion of the instruments of finance (Part II), the book gives a more specific discussion of common stocks by industries than most other textbooks and this is all to the good. However, the short shrift given to the specific problems of the petroleum industry in the chapter on mining securities is puzzling in view of the fact that petroleum shares tend to constitute the largest proportion of the typical investment portfolio.

Public Finance

Essays in Public Finance and Fiscal Policy. By GERHARD COLM. (New York: Oxford University Press. 1955. Pp. xvii, 367. $4.75.)

When Gerhard Colm came to the United States from Germany in 1933, he had already attained a substantial publication record dating over more than a decade, with emphasis on public finance, but with ramifications extending into such fields as international trade and sociology. His move to the United States did not interrupt his flow of writings, and articles on principles of government expenditures and taxation and upon depression fiscal policy began to appear in the American journals. His study of the distribution of tax burden by income class, made with Helen Tarasov for the Temporary National Economic Committee, was the first systematic study of this question in the United States. The war and postwar period saw increased emphasis in his writings on fiscal policy in inflationary periods, the governmental sector in the national income accounts, the national economic budget, and projections of income flows into future periods. From his early affiliation with the New School for Social Research, he moved on to various governmental agencies, including the Bureau of the Budget, and finally, the Council of Economic Advisers, where he served as chief expert in the field of public finance. When the Council was reorganized as a result of the change in administration, he left the government service to become chief economist of the National Planning Association.

In this volume of essays, seventeen of Dr Colm's articles, written between 1934 and 1953, are reproduced, together with one new essay prepared for the volume. Except for elimination of some sections involving excessive duplication, the material is reproduced in unchanged form. The primary emphasis is upon fiscal policy and economic stabilization, with eight articles on this subject. Three articles deal with national income accounts and the national economic budget, four with principles of government expenditures and taxation, and three with the general nature and role of economics and public finance. Unfortunately no material was reproduced from the study of tax burden.

The earlier essays emphasize the extent to which Colm broke away at an early date from the narrow confines of traditional public finance to study the economic effects of governmental expenditure and tax programs, and to advocate the use of fiscal policy as a deliberate instrument for gaining greater economic stability. But he was never an extreme exponent of functional finance; throughout his writings he emphasized the obstacles in the way of successful fiscal policy, together with the problems created by the conflict of the goal of economic stability with other economic goals, and the difficulties of trying to solve by fiscal policy the problems created by other disturbances in the economy. Colm was one of the first to stress the possibility of tax adjustments as an instrument of fiscal policy, in the period in which the whole emphasis was placed upon expenditure aspects. He recognized the importance of flexibility in the operation of fiscal policy, with adjustments in terms of changing conditions, and the ever-present need for evaluating policies in terms

of a dynamic, rather than a static, economy. He has likewise stressed the need for measuring, quantitatively, the various income flows and the precise effects upon them of governmental policy, and for the projection of the data into the future.

So far as the role of economists is concerned, Colm's point of view represents the opposite extreme from that of Lionel Robbins. To Colm the traditional dichotomy between goals and means is an artificial and unworkable one; the economist must consider both, and is under obligation to make policy recommendations, not merely to evaluate alternative means of reaching given goals. Deliberate intervention by the government in economic affairs is regarded as necessary, and not incompatible with the maintenance of democratic institutions. In his work with respect to various types of taxes, Colm argues that the concept of equity in taxation must be developed in terms of the particular stage of economic and political development of the country. In conformity with this thesis, he defends the corporation income tax on the basis of the argument that at present the government is essentially a partner with business firms in the conduct of economic activity, and thus is entitled to a partner's share of the profits. To many, including the reviewer, this argument is nothing more than a flimsy rationalization of the actual treatment of corporate income.

The essays clearly reveal Colm's breadth of vision and interest, and the development of his philosophy of public finance over two decades. But his ability to see the over-all picture, and to break through traditional confines of analysis exceeds the strictness of his logic. The analysis never attains a high level, and abounds with broad unsupported generalizations. His greatest contributions have been those of emphasizing the need for seeing interrelationships of the governmental and private sectors of the economy, in stimulating others to more penetrating analysis, and in popularizing, especially in government circles, the new doctrines of fiscal policy. Along these lines his contribution has been substantial, and the present book may be regarded primarily as a tribute to this feature of his work, rather than as a contribution to the subject matter of public finance. The excessive repetition which still remains, and the lack of comprehensiveness of coverage make the book of little value for classroom purposes.

University of Illinois

The Redistribution of Income in Postwar Britain—A Study of the Effects of the Central Government Fiscal Program in 1948-49. By ALLAN M. CARTTER. (New Haven: Yale University Press. 1955. Pp. viii, 242. $5.00.)

This book seeks to interpret the alteration by government taxing and spending of the size distribution of family incomes in what may well have been the peak year of redistribution by the Labour government. By his careful inquiry Professor Cartter has contributed to the understanding of a subject of wide interest and has advanced comparative study in the field of income distribution, building solidly upon the earlier work of a small group of econ-

omists. Using the findings of Tibor Barna and John H. Adler and others he is able to present the 1948-49 experience in the perspective of prewar British and prewar and postwar American experience.

The leading conclusions reached by the author may be briefly summarized as follows:

1. It should be noted to begin with that out of a total national income of £9.8 billion the central government collected in taxes and disposed of £4.1 billion.

2. All taxes taken together, including a special capital levy, were found to have a progressive effect, ranging from 24.5 per cent of the total of "private income" received by those in the lowest income group (under £135 of taxable income) to 106.6 per cent for those in the highest income group (£20,000 and above). (Table 12, p. 44.)

3. All central government expenditures taken together were found to be distributed regressively. The group receiving under £135 of taxable income "received" benefits equal to 92 per cent of the total "private factor income" received by the group, while those in the £20,000 and over group received benefits equal to only 10 per cent of their incomes, assuming that the indivisible benefits (military, etc.) were distributed proportionally to "net private income." (Table 17, p. 53.)

4. "The breakeven point, or the income at which the average taxpayer contributed in taxes exactly the amount which the government spent in his behalf, fell somewhere between about £550 and £650 of taxable personal income. (In terms of private income, including undistributed profits, the breakeven point was between £700 and £800.)" (P. 63.) Cartter observes that ". . . one can fairly safely conclude that about 80% of the population was on the gaining end, and at least 10% was on the losing end" (p. 120).

5. Excluding indivisible benefits, which comprised £2.4 out of the £4.1 billions expended, the breakeven point was, of course, lower, at about £225 of taxable income. This means that as far as tangible benefits to individuals are concerned only about 25 per cent of the population showed net gains over what they paid in taxes (pp. 54, 120).

6. A summary view of the extent of the total redistributive process may best be afforded by the proportion that posttax and postbenefit incomes were of pretax and prebenefit incomes. The posttax and postbenefit income total for the group having less than £125 of taxable income was 156.7 per cent of the pretax and prebenefit total of income. For the group having incomes over £20,000 the comparable percentage was 12 per cent, including the effect of the capital levy. (Table 25, p. 63.) Of the national income 13.1 per cent was "lost" by some income groups, in the sense that taxes exceeded benefits, and gained by others (p. 79).

7. Comparing the situation with 1937 Cartter found that there was slightly less inequality pretax in 1948-49 than in 1937. But, "... redistribution appears to have been greater in postwar Britain in absolute terms and relative to the national income but slightly less per pound of tax revenue raised" (p. 79).

8. In comparing the British experience with that of the United States, Cartter found that, after adjusting U.S. data to show the same governmental

functions as those performed by the British central government, "Both before and after the war the redistribution of income was substantially greater in Britain. Combining a somewhat more equal initial distribution in postwar Britain with a greater redistributive effort, we find that the distribution of final consumer income in postwar Britain was considerably less unequal than in the U.S." (pp. 91-92).

9. In addition to the immediate redistributive policies, there are long-run programs designed to reduce inequality, which Cartter examines. ". . . the expansion of environmental services and the gradual decline in large inheritances, if these are permanent features, will undoubtedly have a tendency to diminish extreme inequalities of opportunity for future generations" (p. 110). Also, it is emphasized that ". . . there is present in Britain an additional force not included in the previous estimates redistributing incomes *to* persons with large families" (p. 116).

A study of the redistribution of income requires not only considerable economic deductive analysis but also intimate knowledge of the tax and expenditure programs. Further, the study can only be as good as the basic data on income distribution, capital holdings, and consumption patterns allow. The difficulties of seeing the problem as a whole are magnified many times when the attempt is made to compare across time and across national boundaries. Because of the many difficulties confronting the researcher in this field the reader is cautioned against easy acceptance of these conclusions, particularly the comparative statements, as "facts."

Although Cartter provides in Part II of his book a seemingly exhaustive presentation of his methods, there are a number of leaps from sketchy data to complete estimates which emphasize how much individual interpretation is involved. To this reviewer the most glaring example of such "interpretation" is the easy move from a taxable income distribution to a number of other income distributions, which are then used as the basis for comparative study. One of the methods used is to "sandwich" various types of nontaxable income into taxable income brackets without making any estimates of numbers of income recipients who might be in the newly created income bracket. The result is that the income recipient column does not match up in any known way with the income columns. (See pp. 137-51.) No sources are cited for a number of income distribution tables and graphs presented throughout the book. (For example, see Figures 5 and 6 on pp. 75-76.)

While a factual study of income redistribution among income groups provides only limited insight into the qualitative change in social arrangements brought about by the modern "welfare state," such a study is basic to appreciation of the directions in which we are moving.

ROBERT J. LAMPMAN

University of Washington

The Problem of the National Debt. By EDWARD NEVIN. (Cardiff: University of Wales Press. 1954. Pp. 115. 6*s*.)

This compact little book essays two tasks: determining empirically the distribution of interest payments on the British national debt, and proposing

a reform of the debt structure to make it a more effective instrument of economic policy. Details of the empirical study will probably be welcomed by British readers, but Americans will find this section heavy going. However, Dr. Nevin finds the pattern of distribution to be similar to that of other advanced nations, so that the proposals based on his findings are of general validity and interest. For some reason, he does not present any data on distribution measured by capital value, although that would have been relevant to his subsequent discussion.

Over 20 per cent of the interest is currently paid to government agencies (including the Bank of England). Since this leads to budgetary confusion and irrationality, he recommends an end to this method of financing public services. Another 10 per cent of the interest goes to commercial banks, representing a subsidy for banking services. The author recommends that nontransferable securities be issued for bank ownership, the interest determined openly by the subsidy required for the public services they perform. The securities would have no maturity dates, but the banks would be permitted to cash them in at par after a suitable notice period, or to cash them on demand at a discount. The government might redeem these at par after giving the same notice, or on demand at a premium.

For the private owners of the debt, special issues would also be devised. Institutional investors, such as insurance companies, could continue to hold long-term marketable issues with specific maturities. For individuals, nontransferable personal certificates would be issued in small denominations, with redemption and call features similar to the bank issues. These features would protect against a mass demand for redemption.

These measures would very largely isolate each of the major sectors of debt ownership and would facilitate the exercise of monetary policy by permitting the government to deal directly with each independently. Unnecessary turnover of maturing debt would be reduced, but the liquidity of small savers and commercial banks would be safeguarded. By manipulating the terms of issue and redemption, and by exercising its option to redeem, the government could cause any sector to increase or decrease its holdings, thus affecting the money supply and/or the availability of credit to specific sectors. These proposals seem to offer much toward making the debt a functional part of financial policy in any country.

The author could have made some interesting comparisons between his proposals and similar practices actually in use--U. S. savings bonds, for instance, or the bonds issued to banks in the reorganization of the German banking system.

One regrets that the book deals only with problems of managing a debt of given size. The large questions revolving around increasing or decreasing the debt are not discussed. The author has done a good job within the limits chosen, and one laments the omission of other topics because of the feeling that they would have been well treated also.

PAUL B. TRESCOTT

Kenyon College

Fiscal Policy: Its Techniques and Institutional Setting. By JAMES A. MAXWELL. (New York: Henry Holt and Co. 1955. Pp. vi, 218. $2.90.)

In these tightly packed but readable pages, the author offers a realistic, extensive, and nontechnical survey of American techniques and institutions for implementing countercyclical fiscal action. Most of the arguments and conclusions may be found elsewhere in the literature—the author claims no originality in this work—but the skillful integration of political and economic ideas, research findings, description, and historical references into a swiftly developing argument is unique.

Professor Maxwell's core conclusions, developed in the first half of the book, are that discretionary fiscal action ought to be employed after a turning point has been reasonably established, and that built-in flexibility of the federal budget should be relied on as the first line of defense against recession or boom. According to the author, this arrangement is preferable to one which relies on forecasts of economic conditions, because explosive results may be obtained from unreliable forecasting and techniques of uncertain power; political delays and bias tend to negate prompt and rational discretionary action; and structural maladjustments in costs and prices are more likely to be corrected if strong fiscal action operates with a lag. To minimize the dangers of cumulative movements and the inflexibility of a rigid system of built-in stabilizers, the degree of built-in flexibility should not be too strong, but tardy discretionary action should be vigorous. These conclusions are placed in proper relationship to other aspects of policy and the institutional environment in chapters which cover a gamut of subjects from monetary policy and debt management to the work of the Council of Economic Advisers and the Joint Committee on the Economic Report.

Detailed analysis of feasible techniques to increase the degree of built-in flexibility and to implement dicretionary action is presented in the second half of the volume. The author concludes that his computations indicate that the existing degree of built-in flexibility is modest and ought to be strengthened in a number of ways, including, among others, higher per capita exemptions and steeper progression in the individual income tax, longer carry-backs of business losses, replacement of federal public assistance grants with block grants which vary countercyclically, and enlargement of federal grants for state-local construction to provide semi-automatic cyclical offsets. Concluding remarks discuss the implications for democratic liberties of shifting some or all fiscal authority from Congress to the Executive, and end on an optimistic note about present institutional arrangements.

Many exceptions which might be raised against Maxwell's conclusions are weighed in his book and require no additional comment here. But there are some issues which I find inadequately treated. Though there are illuminating references to such social goals as freedom, progress, and equity, economic efficiency tends to be suppressed, except in the discussion of wastes of unemployment and make-work schemes for elminating it. There are a number of comments, more or less related to monetary matters and debt management, which seem extreme in their unqualified form. For instance, the allegation that

short-term treasury financing at low interest rates during 1945-1951 was responsible for inflation (p. 26) is unduly controversial, and the inference that classical writers thought an addition to government spending would produce inflation at full employment (n. 17, p. 11) is surely misleading, if not erroneous.

The conclusion that countercyclical excise tax rate changes should be confined to goods with inelastic demand (pp. 195-98) is, in my opinion, erroneous. As applied to tax reduction, the argument is that tax cuts on products of elastic demand would not reduce excise collections very much, and, by lowering prices of these relieved products, would expand their use and absorb income which otherwise would have been spent on other goods. The effect would be to stimulate the favored industry largely at the expense of others. On the other hand, excise reductions on commodities of inelastic demand release income for expenditure on other goods by roughly the amount of decline in tax collections, and stimulate other industries at the expense of the Treasury. But this argument sidesteps an important consideration. The expansionary effect of an excise cut is roughly equal to the decline of tax collections, and there is *some* rate-cut which will reduce collections on goods of elastic demand —by the full amount in the limiting case of removal of the tax. Though it is true that the expansionary effect in this case directly benefits only the taxed industry and that spending on other products will be more or less reduced, the total expansionary effect on aggregate demand is not for these reasons any less than that of an equal reduction in revenues on goods for which the demand is inelastic. Moreover, excise relief for products with elastic demands should not be denied merely because the industries concerned are the chief immediate beneficiaries, for the demands for their products are often the hardest hit by a general decline in incomes.

These criticisms, however, do not weigh heavily against the many advantages of this book. It is an excellent survey for use in government finance courses, and it can be read profitably by economists in other fields who desire a brief, modern treatment of fiscal policy.

CHALLIS A. HALL, JR.

Yale University

International Economics

Problems of Economic Union. By JAMES E. MEADE. (Chicago: University of Chicago Press. 1954. Pp. ix, 102. $1.75.)

Professor Meade deals with a number of problems, international and domestic, which are involved in the establishment of an economic union. As he characterizes it, the purpose of such a union is to increase levels of living by improving economic efficiency through the creation of a large free-trade area and, perhaps, also through the creation of a large area within which the factors of production can freely move to the most productive employments. He assumes that the countries would wish to do this in a way compatible with the avoidance of booms and slumps and with the maintenance of equilibrium in their balances of payments. The implications of forming such a union for

the domestic economic policies of the countries involved are also explored. The principal conclusion is that large-scale delegation of authority on domestic as well as foreign policies by the nations concerned to the Union's central agency would be necessary to accomplish the objectives of the Union.

The brevity of the book has resulted in the elimination of both rigorous proofs for some of the arguments made and of additional actual or hypothetical examples. Fortunately, however, brevity has not caused the author to limit the scope of the problems to which he addresses himself. Meade presents a welcome objective analysis which sets this problem in a useful perspective.

Attention is first given to the problem of the creation of a single free-trade market within the Union. Using the "welfare" approach, he finds that the members of the Economic Union would have to give up all direct interferences in international trade and payments, including the less obvious protective devices such as customs procedures. Difficult as we know these foreign economic policies are to achieve in practice, Meade also points out that to meet his "welfare" criteria the achievement of the goals of the Economic Union would require important delegation of authority in major fields of domestic policies on monopolies, taxation, defense, etc.

Perhaps for purely personal reasons, the reviewer found most interesting, and would like to devote most of this review to the chapter dealing with the balance of payments, in which Meade considers the question of whether in the modern world there is any practicable alternative mechanism for adjusting balances of payments among the members of the Union other than variations in direct trade and exchange controls. Three different basic methods are discussed, namely, that of "accommodating finance," inflation or deflation, and variation in rates of exchange. The first method, which the very name explains, is regarded as unsatisfactory as a continuing device for meeting a permanent balance-of-payments problem.

The second method of inflation or deflation, as the case may warrant, is also essentially discarded. The discussion of this method is conditioned by the author's basic assumption that the members of the Union wish to avoid either booms or slumps. Meade notes that the problems of adjustment to changes in relative domestic prices would be eased by the removal of trade barriers, free movement of labor and the application of the principle of multilateralism to all monetary transfers between members of the Union. He then goes on to argue that the adjustment of trade flows to changed price relationships would be bound to take time and, in the meantime, there would be need for some accommodating finance to cover the temporary deficits in the balances of payments. Meade seems to feel that, if this method of adjustment is used, it would be best done through instituting a single currency.

The author sees great difficulties in achieving balance-of-payments equilibrium through domestic stabilization policies. The major difficulties would, however, seem to stem at least in part from the either-or method of approach. If one assumes serious problems of disequilibria in many countries, resulting from conditions of advanced inflation or deflation, it obviously becomes a matter of considerable difficulty to achieve equilibrium through changes in

domestic policies alone, or indeed, through any single line of policy. If, however, less difficult conditions are assumed to exist and/or the authorities have available a *combination* of policies, then—and I am sure Meade would agree—domestic stabilization policies become both an essential and feasible part of the program of achieving and maintaining international equilibrium.

Meade is obviously enamored of his third solution, namely, variations in exchange rates. His arguments for exchange rate changes as a means of adjusting balances of payments are quite familiar, and like many others, Meade sees their principal charm in their compatibility with the maintenance of full employment and internal balance. More interesting is his discussion of the use of "free exchange market" versus "adjustable-peg." The first method envisages a free exchange market in which the various national currencies of the countries concerned are subject to the daily or hourly fluctuations of supply and demand accompanied, perhaps, by the intervention of official exchange equalization funds. The second system is that "envisaged under the Articles of Agreement of the International Monetary Fund." According to Meade, under the latter method there are long periods in which "more or less rigid" exchange rates prevail and "then from time to time there are large once-for-all changes in exchange parities in order to restore equilibrium to disordered balances of payments" (p. 46).

Meade is an able advocate of the free exchange market. There is much with which to agree in his arguments; for example, his point that the impediments to trade due to the uncertainties of exchange rate changes are much less significant than those due to an extensive system of exchange controls and import licensing. Others of his conclusions are, perhaps, more doubtful, such as the judgment, which he seems to make, that the problem of competitive devaluation has become much less important— a conclusion which might well be suited to the decade 1945-55, but maybe not to the next decade when satisfactory levels of domestic activity may be coupled with very competitive conditions internationally. His description of the "adjustable-peg" would seem to generalize from a short period of history, particularly the widespread devaluations of 1949, which can not offer a sufficient basis for generalization. The reviewer shares the author's abhorrence of overvalued exchange rates as a cause of balance-of-payments disequilibrium. There is, however, nothing in the method of operation of the Fund which would prevent the mechanism of exchange rate adjustment envisaged thereunder being used effectively as a means of avoiding unrealistic exchange rates. The same factors which cause countries to try to maintain overvalued exchange rates may also operate to prevent the effective functioning of a free exchange market. Intervention by the monetary authorities directly in the exchange market or through limiting access to the exchange market might recreate some of the evils which Meade seems to see resulting from "adjustable-pegs." He notes that for his system of free exchange market "to work at all there must be reasonably reliable principles governing the internal monetary policy of each country. . . . If a national government fails to carry out an effective financial policy for domestic stabilization, the resulting continuing inflation of prices and incomes or the resulting uncontrolled depression will make it quite impossible for any one to judge

whether that member's exchange rate is at any time over-valued or under-valued . . . trade between countries concerned will be subject to wild uncertainties and speculation" (pp. 53-54). It is the conviction of the reviewer that under the conditions set forth for the favorable operation of the free exchange market, and assuming the removal of direct import and exchange restrictions, as is done by the author, the difficulties of successful operation of a system of exchange-rate adjustment as set forth in the International Monetary Fund Agreement becomes much easier to overcome than is suggested by Meade. Both systems are undermined by inflationary domestic policies; both systems become much more manageable under conditions of domestic stability. When domestic stability and international equilibrium (without direct restrictions) have become the rule for some time, we will be in a better position to judge the merits of this controversy of "free exchange market" vs. "adjustable-peg."

Meade also has an interesting chapter as to whether the formation of a single integrated market for products is sufficient to ensure the use of the resources of the group of countries forming the Union in the most efficient manner or whether these countries must also allow their resources of capital and manpower to move freely from country to country in search of the most productive employment. The author summarizes, as the basis for his analysis, Samuelson's arguments as to why under certain conditions freedom of trade and products will suffice. He analyzes what he regards as some of Samuelson's assumptions in order to demonstrate why freedom of trade would not be sufficient in practice. He gives six reasons for his conclusion, namely, differences among member countries in productive atmosphere and in the scale of production; transportation costs; the complete specialization of certain regions on certain lines of production; the existence of a large number of factors relative to the number of standardized traded products; and marked differences in the technical possibility of substituting one factor for another in the different industries producing traded products. These arguments are, of course, limited to the movement of labor, but Meade notes that a similar analysis could be used to demonstrate the need for the movements of capital from capital-rich to capital-poor regions of the Union. He realistically sees and discusses some of the difficulties in achieving the movement of free labor and capital. In effect, it would mean, for example, that member states would have to keep in step in their policies for the distribution of income.

Even this brief summary of Meade's arguments should demonstrate what is perhaps the most important conclusion to be drawn from the book, namely, the far-reaching character and thorough-going nature of a real economic union. It will help avoid the confusion of regarding the transfer to some supranational or international body of one or two precisely defined economic functions as the same thing as the formation of an economic union. In view of the practical difficulties involved, Meade writes that he does not see the possibility of achieving a real economic union between important countries by a single constitutional change, but that he would rather be inclined to advocate the development of the institutions which are already at hand. It may be noted that the preconditions for the achievement of economic union by coun-

tries which are willing to make the necessary political decisions to achieve the advantages of this step, are made easier by further progress in international economic, financial and monetary cooperation. Through such general co-operation countries not only begin to create those economic preconditions which might facilitate the formation of economic unions, but also begin to learn the hard process of adjusting national economic policies to internationally agreed standards and procedures.

IRVING S. FRIEDMAN

Washington, D.C.

International Trade Under Flexible Exchange Rates. By JOHN BURR WILLIAMS. (Amsterdam: North-Holland Publishing Co. 1954. Pp. xiv, 332. $5.00.)

This book, though it claims to present a "new theory" of international trade, actually works for the most part within traditional confines. Its novelty lies in its concentration upon the short run, and in its rejection of multiplier theory as the main tool of short-run analysis. Williams' theory is based on the notion that supply curves for individual commodities are fixed in the short run in money terms, and on a simple version of the quantity theory of money which holds that aggregate spending will change only in response to changes in the quantity of money. The volume of spending, however, is assumed to affect the level of economic activity rather than the level of prices, the general price level being tied to the level of wages, which is assumed to be fixed in the short run. Interest rates are assumed to be determined in the market for new issues of securities, and savings are assumed to find their way into real investment through the market for new securities (p. 165). Hence increases in the desire to save within a country are reflected in interest rates and investment; not in aggregate demand or unemployment. Likewise, changes in the desire to purchase foreign securities are reflected in interest rates and exchange rates; not in aggregate demand or unemployment.

Within this system, where by assumption economic activity is uniquely linked to the quantity of money, it should be no surprise that neither reparations nor exchange manipulation nor private foreign investment will alter the level of economic activity unless at the same time the quantity of money is changed.

Williams relegates consideration of changes in spending to a single chapter of fifteen pages. If payment of reparations is financed by new bank credit, the paying country will experience a rise in economic activity, but this rise will be due to the monetary expansion, not to the transfer itself, as Williams defines it. Under a common currency, as between regions of a country or between nations on a pure-specie gold standard, the transfer of reparations is accompanied by changes in the quantity of money, and the familiar process of inflation in the receiving area and deflation in the paying area brings about the real transfer of goods and services. Here, and only here, is there a direct connection between a transfer and changes in employment. Other cases, involving special assumptions about the policies of monetary authorities, though discussed by Williams, play a distinctly subsidiary role in his analysis.

Williams is the prisoner of his assumptions, and they are not very sophisticated. Yet his analysis serves to remind one of important propositions in the theory of flexible exchange rates, and to make one wonder whether we have not been led, by treating fixed exchanges as the typical if not the general case, to have monetary expansion and contraction buried in our assumptions and never brought to the surface, when really such movements may be crucial to our conclusions.

The book should get one plus and one minus on matters of exposition. Williams relies heavily on complicated systems of graphs rather than on verbal or mathematical analysis, and constant reference to his charts became tedious to this reader. On the other hand the style is lucid and highly readable, and scattered through the pages are apt references to recent experience and pithy, almost aphoristic judgments on matters of wide interest. Let me illustrate and close by quoting Williams' comments on the International Monetary Fund:

> An International Monetary Fund to help stabilize exchange rates has been widely advocated, and one is now in operation. One of its functions is to set fixed rates of exchange, and then revise them from time to time, but only at long intervals and in the face of obvious necessity. The effect is to make the rate change suddenly and in big jumps instead of slowly and little by little. Is this what we really want? The big jumps come far apart, to be sure, but the very size of the jumps in rates may well do more harm than any amount of slow continuous drifting of the rates. The advocates of steady rates say it is hard to close a business deal if rates are rising or falling, even though slowly; but it is even harder to close a deal if rates, though steady today, threaten to jump a long way tomorrow. Since the risk in foreign exchange can be avoided without resort to fixed rates, nothing is to be gained by fixing them as the Fund does. . . . If [a pegged] rate breaks down, it can move only in one direction, and foreign traders are seldom in doubt as to which direction this is. Consequently, whenever they cannot hedge their holdings of foreign exchange, . . . one party to the trade knows that he stands a chance of suffering a serious loss, with no chance of making an offsetting gain. In a free market, however, . . . both parties to a trade feel that their chance of gain is equal to their chance of loss. Likewise, they feel that any fluctuation that does occur is likely to be small. With a pegged rate of exchange, on the other hand, any fluctuation that does occur is likely to be large, with the result that one party to the trade may suffer a crippling loss. For this reason foreign traders do not like a pegged rate (pp. 238-39).

Business Administration

Productivity Accounting. By HIRAM S. DAVIS. (Philadelphia: University of Pennsylvania Press. 1955. Pp. xii, 194. $5.00.)

This book, by an industrial economist who is the director of the Department of Industrial Research, Wharton School of Finance and Commerce of the

University of Pennsylvania, is not so much a work on accounting as it is a description of a statistical technique for measuring the productivity of an enterprise. As the author himself states, "the only justification for giving the name 'productivity accounting' to the method proposed in this book is that it is grounded on basic accounts of a firm, and like usual business accounting deals with all inputs, although in an economic rather than in a financial sense."

The measure proposed is the ratio of total output during an accounting period to the total economic costs incurred to produce that output. Both output and cost are restated in terms of constant prices. The method pursued is to analyze in great detail the financial statements of an actual business, disguised sufficiently to conceal the firm's identity but still reflecting the results of its accounting process as conventionally followed. An illustrative application to this firm of "productivity accounting" is presented first; then follows a lengthy discussion of the theoretical and practical difficulties involved, after which various uses of the calculations are presented. These uses are grouped under five main headings, namely, (1) as a measure of the efficiency of a firm as a whole, (2) as one means of analyzing past performance, (3) as part of the budget control of current performance, (4) as a means of preparing common-price financial statements, and (5) as a device to measure the initial distribution of the benefits flowing from a change in productivity.

Productivity is broadly defined as the "change in results obtained for the resources expended," and consequently includes shifts in the output-input ratio resulting from (a) changes in the production process, (b) changes in methods of using existing processes, (c) changes in the "mix" of input or output, and (d) changes in both the rate and scale at which existing processes are utilized. Specifically, the financial statements of a "given" year are compared with those of a "base" year by restating the recorded dollar amounts of output and input in the given year in terms of base-year prices. The ratio of output per dollar of input for each year is then calculated. The change in the ratio between years is the measure of the change in productivity. This procedure can obviously be extended to the data for a series of years or to a comparison of budgeted with actual figures.

The classification of output follows the familiar accounting and statistical categories of types of product, *e.g.*, commercial grades of rubber, textiles, etc. Input is composed of (1) labor and management, (2) materials, (3) supplies and business services, (4) capital goods (depreciation), and (5) investor input. Each of these categories can be subclassified in specific cases, or analyzed separately, depending upon the objective of the analysis.

The author recognizes clearly that revaluation of output and input in terms of constant prices (*i.e.*, the actual prices prevailing in some base period) means a rating of the component items in terms of their market importance in the base period. As a consequence, the measure of productivity change he obtains is a measure of the change of output per unit of input "in terms of the existing value system under which the production occurs."

This book is excellent for those who wish to use accounting data as grist

for a statistical mill whose output is data on productivity in industry. The practical and theoretical problems are certainly completely catalogued, and, for the most part, satisfactorily handled. What the author never makes entirely clear is why any business management should prefer a change in productivity to a change in profit as a signal to speed up or slow down. Perhaps the increased use of electronic computers in business will enable management to obtain both kinds of data so that a choice between them will not have to be made.

MAURICE MOONITZ

University of California, Berkeley

Les commerces de détail en Europe occidentale—Essai de comparaison internationale de la productivité des magasins et du travail commercial. By JEAN-MARCEL JEANNENEY. (Paris: Armand Colin. 1954. Pp. 73. Fr. 300.)

This study of *Western European Retailing—International Comparison of the Productivity of Retail Outlets and their Personnel* is the first publication of the "Service for the Study of Economic Activity and Social Conditions," an institute created in 1952 by the "National Political Science Foundation" and directed by the author, Professor Jean-Marcel Jeanneney of the Paris Law School.

Using measuring techniques developed by the U.S. Bureau of Labor Statistics and adapted to the distributive trade by the Organization for European Economic Co-operation, Jeanneney attempts a comparative evaluation of retailing productivity in eleven European countries.

With a view to detecting the probable causes of mediocre retailing productivity, the author analyzes eight ratios: the number of food stores, the number of other retail outlets, the number of their respective employees, in terms of population, and annual sales volume.

Great differences in retailing productivity are indicated by the various ratios. If equal weight is assigned to them all, the eleven countries rank, in descending order of productivity, as follows: Sweden, Switzerland and Italy, Denmark and Norway, Great Britain and Germany, France and Austria, the Netherlands, Belgium.

Several attempts are made to explain the differences. Does retailing productivity depend upon geographic factors, such as density of population or degree of urbanization; or upon economic factors, such as the ratio of farmers to total population or the use of industrial power? The only close relationship indicated by the measurements links less-than-optimum retailing productivity to a low standard of living and, particularly, to a low wage structure. Legislation restricting the establishment of new retail outlets, of course, protects inefficient operation.

Despite admitted limitations of the statistical techniques used, this first attempt at determining the productivity of distribution appears extremely interesting. While much remains to be done, the experiment explores a new, difficult, and highly important field. Similar studies should be undertaken of the productivity of wholesaling finished products, and of the productivity of

the process whereby raw materials, component parts, and other producers' goods are marketed in industry. If it is true that productivity of the over-all distribution process depends primarily upon its accurate synchronization with the accrual rate of consumer demand, then studies of this type should be valuable in spotlighting areas in need of improvement, and in facilitating remedial action.

ERIC D. BOVET

Washington, D.C.

Industrial Organization; Public Regulation of Business

Grossindustrie und Gesellschaftsordnung. Industrielle und Politische Dynamik. By HERBERT VON BECKERATH. (Tübingen: J. C. B. Mohr (Paul Siebeck). Zürich: Polygraphischer Verlag AG. 1954. Pp. xii, 278. DM 19.60.)

The dominance of the large enterprise in industry has attracted much attention for many decades. Of economists it can perhaps be said that the large industrial enterprise has been a center of attention for those concerned with economic history and organization, with labor problems, with reformism and socialism, and with such concrete issues of public policy as the maintenance of competition. Economic theorists on the other hand have dealt with big business only recently and with some awkwardness and discomfort. Much the same can be said of those economists who have discussed general economic policy at high levels of abstraction. In his new book Herbert von Beckerath sets for himself a comprehensive problem, that of the meaning and consequences of modern large-scale industry for social structure and development, for the economy as a whole, for politics, and for public policy.

Part one of the book, which is introductory, announces the limitation of the scope to large enterprises in the manufacturing industries. Inasmuch as the author essays evaluations of the political and social aspects and consequences of big business, this indeed must be counted as a shortcoming. Big business is more than big manufacturing, and in the United States particularly, the large nonmanufacturing enterprises, being predominantly private, present public policy issues different from those which have existed in Europe. Large corporations in such fields as banking, insurance, transportation, and communication receive scarcely a mention from von Beckerath; unions are viewed only in the light of their relations to and effects upon the manufacturing industries.

Parts two and three give a sketch of the history of industry in western countries since 1875. Parts four and five are devoted to general descriptive materials on business organization and management, raw materials supplies, sources of capital, labor markets, and product markets. Part six is on public policy and the large enterprise. Here the breadth of Beckerath's knowledge and interests gives the reader interesting contrasts and comparisons among the countries of the West and among general types of economic policy. But here, as throughout, his treatment of each topic is brief, and in parts, superficial.

Because international comparative analysis of the relations among society, state, and industry has not often been undertaken, von Beckerath's comprehensive view is valuable for its insights. He is in a position, as few have really

been, to view in long and in minimally distorted perspective the political economies of both sides of the Atlantic. The contrast between the effects of public policy on the structure of industry in America and Western Europe he handles well. Likewise, the author's characterization of the main types of economic policies, with their political and philosophical orientations, is skillful in the light of his purposes. Beckerath's own point of view can perhaps best be described as conservative in the sense in which that term has appeared in recent political literature in this country. Public policy, he believes, faces the task of preserving and increasing the contribution of large industrial enterprises to economic progress, while maintaining freedom (especially that of the superior people), and at the same time following the dictates imposed by the politics of the age, namely, those of economic stability and the defense of western civilization.

This is not a book to recommend to the specialist, except that some might find in the many references to the French and German literature a source of help. The work is intended as a text and for the general reader. For this purpose its breadth, judicious tone, and its very brevity should make it valuable.

George Washington University

Public Utilities; Transportation: Communications

Transportation and Communications. By G. LLOYD WILSON. (New York: Appleton-Century-Crofts. 1954. Pp. xi, 757. $6.00.)

The transportation industry, despite its great age and maturity in many respects, is still growing and changing, so that a new textbook is imperative every few years. Therefore, this book, by the chairman of the transportation and public utilities department of the Wharton School of the University of Pennsylvania, is a timely arrival. Since transportation textbooks are essentially factual presentations of the transport industry—its history, facilities, practices, and problems—they cannot differ radically in content, and must be judged on the basis of clarity, logic of arrangement, and relative emphasis.

Those well acquainted with the field of transportation will immediately recognize in this book a strong family resemblance to the long-popular Johnson, Huebner, and Wilson text *Transportation—Economic Principles and Practices.* The general arrangement is the same; what might be termed the *vertical* approach, that is, each of the various means of transport is considered separately in all its aspects. Other texts may follow the alternative approach of taking up various functional aspects of transport, such as rates, regulation, etc., and considering each of these with reference to all forms of transport. This too has its advantages, but many of these texts, and especially those which have tried to combine both approaches, have frequently bogged down in confusion and repetition.

A unique feature of this book is the inclusion of five chapters on the communications industry--telephone, telegraph, and radio. This is an area, closely related to transportation, which is all too often entirely neglected in college curricula in business administration.

One criticism of this book is its occasional lapse in presentation of the latest statistical data available. For example, in one of the introductory chapters, a table giving the distribution of freight and passenger traffic among the various agencies of transport uses 1939 figures, although later in the book there is a discussion of the relative shares in 1952. In the chapter on passenger service, reference is made to the federal transportation tax as 15 per cent, but seven pages later the reduction of this tax in 1954 to 10 per cent is recorded (though a typographical error makes the date 1944). Slips like these, while annoying, are not too serious, since they are few and any competent instructor can make the necessary corrections.

The important fact about this book is that it is eminently teachable. Instructors who wish to rely heavily upon a text will find that it contains ample material for a semester course, while those who prefer to create their own course will find the book an excellent framework upon which to hang their own material. It will serve equally well as a text for the only course in transportation, or for a basic course which is to be followed by advanced courses on specialized areas of transport.

Although transportation is a subject in which it is very difficult if not impossible to divorce the theoretical from the practical, it should be pointed out that the emphasis in this text is somewhat heavier upon the practical approach. For instance, in the discussion of railroad rates there is slightly more emphasis upon *what* rates are than upon *why* they are what they are; and in regulation more space is devoted to the provisions of the regulatory laws than to the philosophy of utility regulation. In short, the author has evidently tried to describe what the *user* of transport needs to know about the American transportation system.

Industry Studies

The New England Fishing Industry—A Study in Price and Wage Setting. By DONALD J. WHITE. (Cambridge: Harvard University Press. 1954. Pp. xvii, 205. $4.00.)

Apart from a few dedicated souls in government agencies, professional economists have shown remarkably little interest in the fishing industry. Yet its history of bitter internal disputes and repeated antitrust actions provides ample evidence of the need for analysis of both market structure and market performance. Dr. White has undertaken this task with respect to the important fresh and frozen sector of the New England fisheries centered in Massachusetts and Maine. Though the analysis is centered on the seriously disruptive conflicts among fishermen, vessel owners, and buyers, it is prefaced by a concise summary of the basic structure of the New England dockside markets and concludes with a series of specific policy recommendations.

The author is obviously thoroughly familiar with the technical and organizational background of the New England fisheries, and his delineation of the proximate sources of their troubles—the interrelationship of prices and labor

compensation through the lay payment device; the pressure of declining fish populations; and the mounting volume of imports—is convincing.

Nevertheless, while this is a useful book of professional calibre, it fails to develop the interrelationship of market structure, behavior, and performance in the precise manner characteristic of the many excellent industry studies produced in what might be termed the Harvard tradition.[1] For example, there is no analysis of the degree of concentration among waterfront buyers or of the possibility that coordinated purchasing policies could develop and persist without overt collusion. This is vital to an understanding of continued conflict among dealers and fishermen, since—contrary to White's assumptions—the supply function of primary producers in the fisheries is typically inelastic to price decreases in both short and long run.

Perhaps because of the brevity of the book, a number of its conclusions are inadequately supported. There are, for example, better reasons for rejecting a price support program in the fisheries than that it would result in "putting the union at the mercy of the government" or "undermining the New England industry's will to self-improvement." And the implication that marketing margins are excessive is supported only by the fact that they are high.

White's recommendations with respect to the futility of import restrictions, the need for basic research on both biological and economic fronts, and the desirability of expanding and stabilizing the demand for seafoods are sound. But the key question of the establishment of orderly and competitive pricing procedures at dockside will not be resolved by his suggested changes in the mechanics of pricing, though they are sound. Until the bases for recognized interdependence of buyer purchasing policies are eliminated the turmoil on the waterfront is likely to continue; and this is hardly touched upon in the book.

JAMES A. CRUTCHFIELD

Land Economics; Agricultural Economics; Economic Geography

World Population and World Food Supplies. By SIR E. JOHN RUSSELL. (London: George Allen & Unwin Ltd. 1954. New York: Macmillan. 1955. Pp. 513. $8.50.)

The central purpose of this work is apparently to survey the nations of the world with respect to "what each is doing to increase its contributions to the world food market or to reduce its dependence thereon" (p. 6). The method is to show, by analysis of the history of current practices in agricultural organization and technique in each of several countries, those roads to enhanced food output which may be followed in others somewhat similarly situated especially as to climate and soils. Attention is consistently directed to the successive gaps between "freak" yields, achievement under experimental conditions, outputs of the best farms, and results obtained by average and inferior producers. Ways and means of agricultural improvement and development being the main subject matter, the volume has particular interest for readers concerned with problems of underdeveloped areas. There is a wealth of specific information,

[1] For example, the works of Bain, Markham, Steiner, Alhadeff.

pertaining to specific places, on current practice *vs.* scientific knowledge about irrigation, land reclamation, water conservation, correction of soil deficiencies, use of fertilizers and insecticides, soil and pasture management, plant and animal breeding.

Consideration of the gaps between practice and knowledge in agriculture leads Russell to conclude (p. 7), "the picture that finally emerges is one of tempered optimism." He holds higher expectations of improved food supply for advanced countries than for the underdeveloped ones, for temperate zones than for tropical, for South American tropics than for the African and Asiatic. On food imports for the United Kingdom, he thinks (p. 495) "we may feel hopeful about bread grains, margarine, milk, bacon, pork, and mutton at present levels of consumption, also sugar, fruit, and vegetables. But we cannot rely on pre-war supplies of butter or of beef however much we may hope for them." As for the less advanced countries, he believes (p. 7) that "all can, if they will, find a basis for cooperation with the countries that can supply them [with appliances lacking domestically but needed for improvement of their agriculture] and provide experts teaching how to use them." Apparently his expectations for the underdeveloped areas would be higher if political leaders in those parts of the world showed more evidence of hospitality to capital imports and foreign experts than they do.

Such conclusions indicate that Russell is not greatly troubled by "the population problem," perhaps in part because he restricts his probing of the future to "our time" and says nothing about matters indefinitely remote. He speaks, it is true, in favor of a "sound population policy" for the less advanced countries, India in particular; but the point is made briefly and casually, and what such a policy might be or how implemented receives no discussion at all

The book is somewhat narrower in scope than its title suggests. Excluded from more than passing mention are the USSR and satellite countries, Western Germany, Austria, Switzerland, Greece, Morocco, Algeria, Tunis, Libya, Ethiopia, Turkey, Arabia, Iran, Mexico and Central America, the Caribbean islands, the Philippines, and a few others. Considering the purpose of giving illustrations of roads to agricultural improvement, omission of Turkey and Greece appears especially regrettable. There is a brief, somewhat perfunctory, introductory chapter on world population numbers and growth, and a longer concluding chapter on trends in world food supplies especially as they bear upon prospects for British food imports. Otherwise the treatment is by geographical areas *seriatim:* British Isles (54 pages); Netherlands, Denmark, Sweden, Finland (54 pages); France, Spain, Portugal, Italy, Israel, Egypt (50 pages); Africa south of the Sahara (135 pages); India and Pakistan (27 pages); China, Japan, Indonesia, Burma, Thailand, Indochina (9 pages); the United States and Canada (46 pages); Australia and New Zealand (47 pages); and Argentina, Brazil, Uruguay, and Paraguay (22 pages). Opinions will differ on the relative merits of the regional analysis. The present reviewer happened to derive least satisfaction from the discussions of Asiatic countries, Spain and Portugal, the United States, and South America; most from the discussions of Israel, Egypt, Africa below the Sahara, Australia, Finland, and Canada.

Although publication was in 1954, the author usually found himself unable to present statistical contrasts of prewar circumstances (acreage, production, consumption, land use, etc.) with circumstances in postwar years later than 1950, sometimes 1951. Commonly the crops of 1952, 1953, and 1954 were far larger, so that in not a few countries where the earlier data suggested deterioration of yield and lower consumption, later information suggests the reverse. Writing today, Russell might well find less reason to temper the optimism of his conclusions than he found two years ago.

Food Research Institute, Stanford University

Labor

Labor-Management Relations in Illini City. By W. E. CHALMERS, MARGARET K. CHANDLER, L. L. MCQUITTY, ROSS STAGNER, DONALD E. WRAY, and MILTON DERBER. Vol. 1: *The Case Studies*. Vol. 2: *Explorations in Comparative Analysis*. (Champaign: Institute of Labor and Industrial Relations, Univ. of Illinois. 1953, 1954. Pp. xlii, 809; x, 662. 2 vols., $15.00; each $10.00.)

Economic books should be accurate and thorough, but, once ready or approximately so, they should be rushed on the market. The reasons were suggested years ago by Richard T. Ely in defense of his own policy of prompt publication. They are, essentially: that the world has great need of all the enlightenment that can be offered in this field; that the product is highly perishable; and that some other chap may beat you to the draw. The present study, after the manner of elephants, has had a long period of gestation. The interviews and research upon which it is based covered the three years from 1948 to 1950, inclusive; the first volume, which is primarily a case-book, is dated "1953," but it had to stand by until its somewhat less hefty brother could appear at its side late in 1954; and now both are being reviewed in 1955. We cannot at this distance know all the difficulties, mechanical, controversial, and otherwise, that may have been encountered. Certainly, there has been no undue economy of time or space, or of thought and effort. The authors may well declare that they are writing for the future and not merely about the past.

This is an example of cooperative research and analysis among the social sciences; and not the least interesting feature for the profession itself is the brief account toward the very end by Chalmers of how it worked. The three disciplines immediately concerned were economics, sociology, and psychology, with political science on the side-lines. We are told that the participants first had to educate one another, and this may have been part of the time-consuming process which would not have been so necessary in olden days when an academic chair was more in the nature of a settee. We are not told which one of the triumvirate finally ruled the roost; but, judging from the fondness throughout for certain modes of expression, the emphasis upon methodology, and the use of such mouth-filling terms as "accommodation," "quantification," "circular influence," and "norms," it appears that it was not the economists,

and may have been the sociologists or their near relatives, the institutionalists. Yet there can be no doubt but that labor relations offer scope for all methods and viewpoints, and that such a newer synthesis or integration is highly desirable. We have Sir John Clapham's authority for saying that "it is at the overlapping margins of disciplines and sciences that the most important discoveries are usually made."

Some disappointment may be felt that we are given so much information about industrial affairs in an unidentified city of 50,000 or upwards, and that the names of companies, labor leaders, and historical characters are so carefully concealed. But perhaps we have become somewhat accustomed to such anonymity through parallel studies like "Middletown," "Yankee City," Steeltown" and others, which are sometimes here referred to, and can understand that confidentialness is the price that must be paid for freedom of expression and fullness of data upon a live, current situation.

The end-purpose of the study was to arrive at certain positive criteria or scales for measuring labor-management relations within a given community, industry or plant, whether they are to be regarded as good, fair, or poor; to determine the principal factors or influences bringing them about; and to show how the different features or variables are correlated. The community chosen is a medium-sized city in the Middle West with a considerable variety of industries but a relatively homogeneous population with respect to race and culture. It is fairly typical of its area but not necessarily of all areas. The industries selected for special investigation were five in number, in three cases represented by two different establishments or concerns each: a grain-processing company with quite a long history; a plumbing-supply or metal products plant; building construction firms; garment factories making house-dresses and employing chiefly women; and the local and over-the-road trucking business—making eight different units in all.

The goals or tests as to the level of success achieved in each industry and establishment are mainly three: (1) the present economic status of the workers as shown in average hourly pay and annual earnings; (2) the extent of union influence as shown by participation in the decision-making process on various phases of the business (wages, hours, accidents, seniority, time study, etc.); and (3) the attitudinal climate as registered in the frequency and bitterness of conflict or the existence of a spirit of cooperation between employers and employees. Among the determinants of successful industrial relations are given such factors as the attitude of the community toward unionism at different periods and the extent to which union leaders are represented in civic affairs; the influence of national psychology and legislation under the New Deal; the baneful effect of absentee ownership as contrasted with a neighborhood feeling; regional as compared with local leadership of labor; the change from the paternalistic or the captain-of-industry to the more professional type of management; the importance of business prosperity; the proportion which labor cost bears to total cost, and so on.

Perhaps the least revelatory portion of the analysis in Volume II is that on the "determinants" in Chapters 8 and 9, where so many of the hypotheses

as to what makes for greater or smaller union influence or for improvements in economic status seem axiomatic and not really necessary of proof. It is true that in our classes we often shape up hypothetical questions the answers to which are already known, just as an exercise for the students. But it seems rather unprofitable in a scientific treatise to devote pages to demonstrating that hourly wages tend to be higher where the regularity of employment is low, or that "If the skill level is higher, the hourly earnings tend to be higher." Adam Smith said most of these things in 1776 and no one has ever seriously disputed them, always remembering to add, "other things being equal."

It is much too late to give advice as to how the avoirdupois of this treatise could have been reduced. That would seem to have been eminently desirable both from the standpoint of publishing costs and for the comfort of the reader. The plan of treatment may be what is commonly called a spiral one or the method of approximations. But surely we are conscious of returning again and again, as in a nightmare, to the same material stated in almost identical language. Summaries and conclusions at the end of each chapter and division, and at the end of Volume II, are so frequent and complete that any passenger who dropped off at a way-station to get a sandwich or a newspaper would have no difficulty in jumping on again when the last car came by. In fact, it might be just as well to begin with Milton Derber's "Summary of Findings" in chapter 16 where there are ample cross-references to all previous discussions of each topic, and then "proceed backward" from there.

WARREN B. CATLIN

Bowdoin College

The French Labor Movement. By VAL R. LORWIN. (Cambridge: Harvard University Press. 1955. Pp. xix, 346. $6.00.)

This reviewer heartily hopes that the many persons now engaged in comparative labor studies will use Professor Lorwin's *The French Labor Movement* as a model of organization and balanced presentation. Few American writers, of course, will bring to such a study the long familiarity that Lorwin has with his subject. The French labor movement has been in the Lorwin family for a long time. Val Lorwin's father, Lewis L. Lorwin, published his *Syndicalism in France* forty years ago.

The first half of this book is devoted to describing the rise of French unionism, a product of the unique social history of that land, its syndicalist origin and its later capture by the Communists. It was, ironically, the individualism of the French workers who refused to give either funds or authority to their union leaders that kept their organization weak, thus easy prey for the well-disciplined Communists who moved in at the time of liberation.

Lorwin describes how the bright hopes that French labor held at the war's end have been dashed, the Communists in control using the major federation, the Confédération Générale du Travail, to further Soviet policy and in disregard of the interests of labor and the French economy as a whole. Yet even the CFTC, the Christian Federation, and the *Force Ouvrière,* the group that broke from the CGT—both of them closer to the more immediate objectives of the

concrete wage earner, not the abstract "proletarian"—have been unable to rally the kind of day-to-day support a trade union movement needs for growth and effective action.

Although the Communists are in control of the apparatus of the CGT, they are no more successful than their predecessors or their rivals in mobilizing the membership for their own objectives.

That collective bargaining as Americans know it hardly exists in France is brought out in the second half of the book, where industrial relations and the role of government in labor affairs are described. The well-organized employers, who view their markets as inelastic, determine the area and scope of such bargaining as exists. The competition among the federations and the apathy of the workers make this task easy.

As long as the major segment of the French labor movement continues to treat "bourgeois" government as its principal enemy, it will go on depriving itself of the alternate, governmental route for an amelioration of the workingmen's condition of life as well as for upbuilding the bargaining power of its unions.

This excellently written book has added usefulness for the teacher and student because of its complete bibliography, chronology, and appendixes.

Edwin Young

University of Wisconsin

The Union and the Coal Industry. By Morton S. Baratz. (New Haven: Yale University Press. 1955. Pp. xvii, 170. $3.75.)

The first three chapters of this book present a description of the market structure of the coal industry and of its most important producing area (Appalachian Region) followed by a historical review of "significant developments" of the sixty years closing in 1950. Chapters 4 and 5 are outlines of "policy objectives" of the United Mine Workers, and of the "political aspects" of union action in its internal operation, as well as in its management-government relations. The last four chapters deal with the effects of union activity upon wages and market competition (both interregional and interfuel) with a concluding appraisal of these effects.

The long first chapter furnishes the foundation. It is an old familiar framework consisting of two elements—one is the view that "a distinguishing characteristic of the industry is the vigor of price competition among many firms," and the other, that "union-enforced 'floors' . . . have curbed the use of wage cutting as an instrument of competition." The view of the industry as an almost perfect example of "pure competition" (p. 27) may have been an acceptable basis for Lubin's[1] study of collective bargaining in the 'twenties, but Parker[2] recognized its oversimplified character in 1939-1940. The "pure competition" view was never more than symbolically correct, and it became seriously defective after 1941 when unionism encompassed the steel companies' "captive mines." No mention of the significance of standardization of wage

[1] I. Lubin, *Miners' Wages and the Cost of Coal* (New York, 1924).

[2] G. L. Parker, *The Coal Industry* (Washington, 1940).

scales in this market-sheltered segment of the industry occurs in the first chapter, but later efforts to repair the defect constitute the most original contributions of the study. Had some of these been supported by convincingly presented fresh evidence, they might have counted as strokes of real craftsmanship. Unfortunately these efforts to deal with consumer-owned tonnage come too late to do more than introduce mere fragmentary bits of rare materials into a framework of pure competition where they have no place (pp. 28, 30, note 7, 37-38, 80, 82 and 141). Not only do the materials fit the structural layout very badly, but they also show marks of inept handling. Thus in considering the union-reduced working time of 1949, the author writes, "This was an attractive proposition to many firms, but it was resisted strenuously *by the captive mines—all of which could sell a full week's output* (p. 141, reviewer's italics). If we skip the very real question of whether it is appropriate to refer to the captive mines as ever "selling" anything in a conventional sense, there remains the observation that the statement simply is not correct as to the facts. It was based on a newspaper account (note 9), and a little investigation of the reports of the Bureau of Mines would have shown the author the inaccuracy of his statement. Captive mines of steel mills are the principal suppliers of the coke-making furnace plants. During all months of 1949 furnace plant coke reserves were approximately twice as great as in all the corresponding months of 1948.

The book contains many illustrations of the misleading use of the common materials of economic analysis. The course of wages during the period 1935-1948 is discussed with almost no consideration of changes in general price levels during the period. Neither does the section dealing with the elimination of regional differentials in wages take into account that this movement coincided in timing with similar developments in other industries;[3] perhaps something more than unionism was at work. Moreover, the text may give the impression that union scales have obliterated all regional differentials, as there is no recognition of the fact that district agreements still permit noticeable differences in area rates.

Also the casual five-paragraph treatment of the new institution of the U.M.W. welfare fund (pp 115-16) is another illustration of inadequate consideration of important facts. Reference is made to the 1948 rate of 20 cents per ton without any mention that this was raised to 30 cents in 1950 and again to 40 cents in 1952. At the time the author was writing his text (early 1954, see p. 140) the sag of coal prices had made the then current rate represent over 10 per cent of realization-at-the-mine to many operators, an amount too significant to be dismissed with indifference.

This sort of loose procedure can hardly lead to any reliable conclusions and the frail evidence presented cannot support "an appraisal." Hence in the final chapter, with scrupulous documentation it is true, refuge is taken in summarizing views advanced earlier by other writers. With its substantial reliance upon the ideas of Arthur Ross, Henry Simons, Lloyd Reynolds, and C. E. Lindblom, this final chapter could have been written, save for minor changes,

[3] See W. S. Woytinsky et al., *Employment and Wages in the United States*, esp. Ch. 41, (New York, 1953).

without any reference to the earlier portions of the book. Thus the reader is left with very little fresh enlightenment on "The Union and the Coal Industry."

C. L. CHRISTENSON

Indiana University

An Introduction to the Study of Industrial Relations. By J. HENRY RICHARDSON. (London: George Allen and Unwin Ltd. Distributed by Macmillan in the U.S.A. 1954. Pp. 442. $5.25.)

From a rich background of experience in Great Britain and abroad, Professor Richardson of the University of Leeds has written what he terms a comprehensive survey of the field of industrial relations. Although the aim is not stated in terms of any one particular industrialized country, the book leaves the impression of being a Briton's view of policies and practices in his own country, with only oblique references to America and other countries. The American reader's interest will more likely stem from a desire to make comparisons of viewpoints than from a search for new or old knowledge challengingly presented. He will be interested for example in perceiving the extent to which our techniques in personnel administration find their parallels in Great Britain while our philosophies on collective bargaining and state intervention do not.

It should be pointed out at once that Richardson's definition of a comprehensive survey is not the same as an American's definition of a textbook in labor economics and labor relations. Thus when Richardson turns to the subject of wages, he deems it sufficient for his purposes to concentrate on the wage-setting mechanisms and on the key arguments influencing the wage settlement. He does not analyze in any detail the economic significance of the bargains arrived at, nor does he relate the wage-setting process to distributive theory in economics. In general, Richardson's survey stops at a description of institutions and techniques, and does not push on into examining the consequences flowing from those institutions and techniques.

In five separate areas, the author describes contemporary institutions developed by men in pursuit of better relations between employer and employed and better standards of living for all. Beginning with relations at the workplace in the face-to-face meetings of worker and boss, he treats the standard subjects of personnel administration. From this, he moves on to introduce the institutions of unionism and of collective union-management relations. Next he allots a section to the problems of wages and hours as those problems manifest themselves in the private sectors of the economy. The role of state intervention in the wage policy, conciliation, and social security fields carries him on to the national level. From there, it is only a short step to the international sphere and to a brief description of international labor organizations.

The tour here is a quick one and the guide is well informed. Yet there are two related problems about such a tour and Richardson effectively solves neither of them. First, there is the guide's temptation to hold us too long in one place that is of special interest to him but that is not explained to us in such a way as to arouse our interest. For this reader, too much time is spent

for example on a rather detailed description of the Bedeaux system of work measurement without developing those basic principles which add understanding as opposed to skills. At such points, the guidebook takes on the air of a manual. If one were to use this book as a classroom text, he would be at a loss to provoke discussion that lifted the students' sights beyond the details of technique and toward the economic and sociological implications of the Bedeaux system.

The other problem flows directly from the first one. The guide then must make up for lost time and needs to rush us past other spots with a few broad generalizations. With Richardson, such generalizations as are sprinkled throughout the book invite dissent in many instances and further clarification in others. Two examples: "It must be emphasized that there is not the slightest objection to time studies if the method is properly used. Indeed, for suitable work time studies are of value both to management and workpeople, and if standards of output are fixed by mutual agreement as they usually can be they remove a cause of friction and lead to more harmonious relations in the undertaking" (p. 73); and, "In some countries, *e.g.*, the United States, misunderstandings are still the cause of bitter costly conflicts, but in Britain the prospects for constructive advance are favorable" (p. 159).

There is furthermore an ambiguity of purpose which shows through in these pages. This takes the form of occasional lapses from objective description into policy prescription. My quarrel is both with the appropriateness of including any advice at all in such a survey and with the wisdom of the particular advice given here. Here are two instances of these prescriptions: "Clerical work has long had a higher prestige than many manual occupations—because of higher social status. Where this distinction is merely snobbish, it should be broken down" (p. 102); and, "One road to greater harmony in industry would be for workpeople to become part owners of the capital they use and to have a more direct interest in the profits of industry" (p. 429). In a book otherwise notable for dispassionate description, these passages are strangely out of place.

Carnegie Institute of Technology

Population; Social Welfare and Living Standards

A Theory of Economic-Demographic Development. By HARVEY LEIBENSTEIN. (Princeton: Princeton University Press. 1954. Pp. xi, 204. $4.00.)

Professor Leibenstein concludes his book with the following remarkable sentence: "As a consequence it appears that to attempt to suggest means of testing propositions developed in this essay is at present otiose." This is true, he feels, because (1) scientific propositions can be tested only if they lead to predictions which then turn out to be true or false. (2) These predictions can not be tested because the variables discussed are not measurable—either for lack of statistics or lack of techniques of measurement. (3) Finally, by the time the statistics and techniques are perfected, the author feels that a more adequate theory of economic-demographic development can be evolved.

Such modesty indicates that instead of laying claim to having slain the

dragon of Malthusianism, Leibenstein presents himself as something of a reluctant dragon. What he is here saying is that his model for economic-demographic development has not been—and should not be—subject to empirical analysis and verification. Is it therefore useless? Evidently he does not think so and, I am glad to say, neither do I.

Needless to say this is a work in pure theory—a model highly simplified but apparently, like many models, complicated enough to defy empirical verification. Basically this model sets the rate of population increases against the rate of accumulation of capital in Malthusian countries and attempts to estimate the "critical minimum effort" required to pull the "system" out of its "stall" on dead center.

It sees the "Malthusian trap" in the undeveloped countries as tending to a stable equilibrium, with the major variables at an extreme value consistent with the survival of the population. Thus (1) population size tends to be at a maximum in relation to given resources, technology, and economic organization; (2) per capita income tends to be at a minimum consistent with population survival; with (3) birth and death rates at the maximum consistent with survival.

If we inject into this system given increments of income, what will happen? Will the increased average income lead to population growth, thus lowering income? Or will increases in average income lead to more saving, thus increasing the rate of capital accumulation faster than the rate of population increase? Here one has a choice of two models. (1) The rate of population growth can be regarded as a monotonic increasing function of average income up to a point beyond which the rate continues at its maximum value; or (2) it can be postulated that above a certain level of average income, the rate of population growth will decline.

In this moving series of equations, what is the "critical minimum effort" necessary for the destabilization of the Malthusian equilibrium? Under certain conditions attempts to escape Malthusian stagnation will—when they fail—make the situation worse. For the average income-gain multiplier to be larger than the population multiplier, the investment for example should be labor-elastic in character. Thus it is better to build a railway system than to invest in the production of agricultural machinery which at the onset will displace labor. Later, however, fewer workers must grow more food to supply urban industrial populations.

The first explanations are developed at the "macro" level of the total systems—economic and demographic. Ultimately, however, the analysis must get down to the "micro" level; that is, it must consider individual choices, that is, the decision-making process in terms of both the technological and biological constructs involved. Here the analysis attempts to integrate the economic order with the *mores* and social values involved in the high fertility complex.

This represents a complex system hardly more amenable to the symbols, curves, and equations of a certain type of economic theorist than to the conventional verbalizing of the orthodox cultural demographer. No model can

include all the variables involved in the real situation. Actually the more "micro" the model, the more variables that are left out. How many can be left out and still give us a model which is functional or "workable"? Aye, here is the rub; it leaves both the author and the reviewer feeling somewhat otiose.

The volume ends with a chapter on optimum population theory which adds little either to the model or to the concept of the optimum. This book is distinctly not the cup of tea to which demographers of the sociological variety happen to be addicted. Nevertheless, it is something which required doing. It is also something which for the good of my empirical little soul, I am glad I have read. I do predict, however, that if—and when—some of the backward countries break out of the Malthusian trap, no one will refer to Leibenstein's book as having had anything to do with it. This will be unfortunate and if I am around at the time, I hope to remedy the oversight.

RUPERT B. VANCE

University of North Carolina

Employment Expansion and Population Growth—The California Experience 1900-1950. By MARGARET S. GORDON. (Berkeley and Los Angeles: University of California Press. 1954. Pp. xiii, 192. $3.50.)

Dr. Gordon's monograph continues a series of historical studies of California's population and economy sponsored by the Institute of Industrial Relations at the University of California (Berkeley). The major emphasis of this study is on the relation of inmigration to economic growth in the first half of this century. In this context, the author examines the degree and timing of changes in the size and structure of the population and in the levels and structure of employment; comparisons are made with national trends, and differentials in income and unemployment between the state and the nation are analyzed. In the course of interpreting the interrelationships of population and economic growth, a number of interesting hypotheses are tested.

A major finding of the study is that the state's highest rates of inmigration were associated with rapid expansion in employment in California, and the time periods concerned coincided with those of rapid expansion in the nation. It is recognized that the reasons for migration to California may be noneconomic as well as economic in nature, but the evidence suggests that the timing of migration is strongly influenced by the levels of job opportunity prevailing in the period concerned.

Historical data on unemployment are also used to support the view that net migration to California is sensitive to changes in the rate of economic expansion. The only instance of a serious maladjustment between the two was found in the persistence of a relatively high rate of unemployment in the state during the years following the second world war. After comparing migration waves to California and to other selected states, the conclusion is reached that migration waves may be related to secondary secular swings in the rate of growth in the national economy.

The author finds no evidence that extensive inmigration to California has led to a decline in long-standing wage differentials between California and

other regions of the country. A recent decline in per capita income in California is attributed not to a decline in wage income but to a change in the structure of the population, namely, a decline in the relative underrepresentation of children, and to a decline in the relative importance of the extractive industries in the economy.

Despite an increase in manufacturing employment in recent decades, this report indicates that the structure of employment in California has been remarkably stable over a half century and that the state continues to have substantially higher proportions of workers than the nation in the distributive and service industries. Most of the manufacturing industries that have flourished in California have been "market-oriented" or owe locational advantages to the state's natural resources, including climate. As a result of the most recent developments, California's economy has become increasingly dependent on the level of spending for national defense.

Dr. Gordon finds that the hypothesis that California's economy is less vulnerable than the nation to cyclical changes can not be adequate tested from the available data. Employment in the state is found to be subject to relatively high seasonal variation in some industries that employ a substantial proportion of the labor force. Moreover, lags in fluctuations in the rate of inmigration compared with employment changes have occasionally led to a relatively high volume of frictional unemployment.

The evidence with respect to the effect of population growth on the pattern of industrial expansion is inconclusive, partly because of instability in the development of certain industries and persistent declines in the national and regional demand for labor in others. A methodological problem is raised by this part of the analysis. Apart from the validity of the assumption that all types of employment may be expected to expand with population growth, this reviewer questions the use of ratios of the rate of change in one to the rate of change in the other as a major indicator of trends, because ambiguous figures result if one rises and the other declines.

The major findings of the study are not affected by this methodological defect, however, and the report will be of interest to all regional analysts and to economists concerned with the geographic impact of national developments. More importantly, this is one of a very small number of regional studies that attempt to test important aspects of economic and social theory about economic growth and migration.

GLADYS L. PALMER

University of Pennsylvania

Hungry People and Empty Lands. By S. CHANDRASEKHAR. (New York: Macmillan. London: George Allen and Unwin Ltd. 1954. Pp. 306.)

This is basically a "tract for the times." Like many predecessors, it stresses the urgency of the population problems in underdeveloped areas, and presents a policy to deal with those problems. The thesis is simple and is no longer original. If the present rate of population growth continues in such countries

as India and China, the growth will swallow up any potential gains from industrialization and agricultural development. This will make the achievement of higher standards of living in those countries impossible, and could lead to such explosive internal pressures within the countries that demands for new land would become irresistible and war would result. To avoid these contingencies the author advocates a series of policies laying stress upon migration to currently "empty" lands, accompanied by birth control, as well as the usually advocated measures of industrialization and agricultural development.

The book deserves praise for emphasizing the possibility of migration. It examines the population-absorbing capacities of those countries that the author considers would be able to profit from large-scale immigration of peoples from the "crowded" countries. However, the book has many weaknesses. The major one is that the author sacrifices factual support and close reasoning for a supposedly popular and frequently weak level of argument. While the reviewer sympathizes with the author's position and agrees with him as to the urgency of the problem, he is unable to accept many of the arguments presented. A major argument, frequently repeated in the book, is that the pressure of population upon land is the basic cause of war. Unfortunately the author cites as strong supporting evidence Hitler, Mussolini and Japanese military leaders. The author obviously has failed to distinguish between rationalizations for policies and the causes of the policies. Furthermore, when the author states that even if the argument may not hold in "fact" it would be equally valid if it held psychologically, he is making the argument one that it is impossible to disprove. It cannot be put to any test and therefore is not valid as a scientific argument. In fact the cases of Germany, Italy and Japan may show that even with relatively high and increasing living standards countries may be induced into war by the sight of *higher* standards among other countries, rather than by their own absolute level of poverty.

This same weakness characterizes the discussion of the "empty" lands. The reviewer agrees with the criticisms of racial limits to immigration, especially as the author himself recognizes that any migration on a large scale must be accompanied by birth control among the migrants and in the "home" country if it is to be part of a policy toward a solution rather than a "palliative." However, the author never in fact supports his arguments that the "empty" lands can in fact *now* support large populations. Rather he usually presents statements, and these statements do no more than contradict statements to the contrary. The author may also confuse the capacity of a country to absorb migrants *physically* and its *economic* capacity to absorb migrants.

The author cites the Japanese experience with industrialization and population growth to support his argument that population growth absorbed the gains of economic development and led to war. Lockwood's recent thorough study of Japanese economic development from 1870-1937 does not support this argument. Rather Lockwood shows that, while population growth probably did *not* on balance assist Japan's economic development, nevertheless Japan's economic development in all sectors of the economy and its entrance into the world market did lead to a steady growth in per capita income. Only

when Japan sought to become self-sufficient did the leaders find that its internal resources were insufficient to support the population at higher income levels, to develop an Empire, and to support a great war machine. Furthermore, even with open land areas in Hokkaido within Japan proper and with an Empire, the Japanese never did migrate to those regions in large numbers.

The discussion of India and China appears to be of more value, not only because it brings together data unavailable elsewhere, but because it provides insights into the problems of those two countries and the difficulties of solution.

The author's policy proposals are of some interest. The suggestions for an International Migration Authority and for a survey of the "open" areas of the world are worth while both for determining certain facts concerning "open" areas, and as a basis for carrying out migration. The discussion of internal population policy and of planned population maxima within countries is provocative, but the reviewer feels that these policies approach oversimplification in dealing with a very complex problem. One wishes also that the criticisms of colonialism added something to the subject, without essentially flogging a "dead" horse.

The reviewer may appear too critical. He is sympathetic to the author's position, and realizes that the author is primarily interested in arousing concern, stimulating discussion, and presenting policy solutions for a very serious problem. The book succeeds partially in these aims. However, by its weak argumentation, both logically and factually, it may discourage, rather than attract, many potential supporters of the author's purposes or policies.

George Rosen

Washington, D.C.

Population. By Ian Bowen. (Cambridge: Cambridge University Press. 1954 Pp. xv, 256. 10 *s.*, 6*d.*)

This short volume is the latest addition to the Cambridge Economic Handbooks. (It replaces Harold Wright's book by the same title, published in 1923.) Like the others in the series it is intended for the "ordinary reader and uninitiated student"—a fact that may be of importance in assessing the value of this particular volume.

The book is divided into three parts. The first contains a brief sketch of the world's and Britain's demographic experience. The bulk of the book, Part II, is devoted to matters of theory. There is a very long chapter on Malthusian theory, and shorter discussions on optimum population theory, population growth and the demand and supply of labor, economic expansion and population growth, and international migration. In the final section we find a discussion of the future prospects of British and world population, and their connection to economic and social well being.

Much of this volume is in the nature of a running argument of one sort or another rather than straightforward exposition of facts and theories. Professor Bowen appears to have definite convictions on a number of questions, and these in large part appear to determine the nature of this work. On the

whole the book is provocative rather than balanced, discursive and general rather than technical, and often appears to be chatty rather than systematic. A great deal of space is devoted to what might be called "What Malthus Really Meant and Why He Was Wrong." Bowen is not especially tolerant of the more charitable interpretations of the Malthusian position, and an explicit anti-Malthusian tone is evident throughout. He appears to believe that there is not very much danger of overpopulation anywhere, since ". . . diminishing returns are not a bogey that ought to frighten anyone capable of discerning the immense ranges of output in all industries, including agriculture, where increasing returns are possible" (p. 150). There are frequent passing references to social scientists and other scholars of varying degrees of fame, but it is to be doubted that the ordinary reader or uninitiated student would have heard of more than a very small proportion of them, at best.

There are many things that demographers talk about that will not be found here. For example, there is no systematic discussion of the various measures and indices of population growth developed by demographers, nor will the reader learn very much about the methods of population forecasting that have been employed in the past. Similarly, the usual discussions of the factors often considered as significant in determining the changing patterns of mortality and fertility are either absent or, when considered, treated only *en passant*, and rather discoursively.

In sum, we might say that this short and highly readable volume will introduce the reader to "the population debate," but many teachers may want their students to get somewhat more of the other side than is likely to be found in this particular handbook.

HARVEY LEIBENSTEIN

University of California
Berkeley, California

Medical Care for Tomorrow. By MICHAEL M. DAVIS. (New York: Harper & Brothers. 1955. Pp. xii, 497. $6.50.)

This book is a gold mine for the field of medical care.

Michael Davis has been professionally concerned with medical economic affairs for more than forty years. He has been at various times an administrator, a director of research, and a reformer. For the last dozen years he has led the fight for compulsory national health insurance. Davis has drawn upon his fund of knowledge to produce the first approximation of an integrated picture of all the variables inherent in our national institutional structure for the distribution of medical care. To do this he has drawn upon the disciplines of philosophy, political science, history, economics, and the medical sciences themselves. An integrative task such as this involves recognizing the limits of the usefulness of each single approach to the subject. It is the sort of task that, though often attempted by committees, is finally possible only within single minds. Here the task is done by a man who has been applying his mind to the problems for a working lifetime.

Many persons may disagree with Davis in special cases. Most persons who

read his book, wherever they disagree, will pay him the immense compliment of accepting his basic assumptions regarding the dynamics of medical care in our society.

The first part of the book deals with the basic facts, and suggests useful working ideas. Economists will wish to criticize Davis' use of the term "demand"; he fails properly to relate the term to purchasing power. But his suggested term "social capital," applied to the public's investment in hospitals and similar facilities, is worthy of much wider application, and suggests exciting analytical possibilities. Davis points out elemental facts that, I am ashamed to say, never occurred to me. One is that though medical charges are incurred by individuals, bills tend to be met by families; this adds to the burden of larger families, and throws doubt on the usefulness of some statistical presentations. There is a useful interplay between description and analysis in this section; he does not attempt to present a great compendium of facts; he lets the argument have precedence, and adds what facts are relevant. A great contribution is Davis' constant emphasis upon the dimensions of the unknown in the field of medical care. We know little, for instance, of how to measure the quality of medical care. Here as throughout the book, Davis refers to any significant contributions which have been made, but also makes clear his own opinion in the matter.

The second part deals with the role of organization in the distribution of medical care, and includes much historical material on the genesis of the organizational pattern of the present. Davis succeeds in convincing the reader that there is nothing particularly sacred about the present situation.

The third part is devoted to health insurance, an institution close to the author's heart. The treatment of the growth and coverage of existing plans is very full indeed. The author writes, "A major consideration is that neither 'catastrophic insurance,' nor indemnity policies, nor insurance of the Blue Shield type offers opportunity for the preventive services . . . which lessen the likelihood of high-cost illnesses themselves" (pp. 225-26). Later he writes, ". . . health insurance is a financial mechanism for a medical end. The mechanism must serve the end and not be an end in itself. Those who elevate precepts of private insurance into immutable principles confuse the end with the mechanism" (p. 262).

The fourth part is a discussion of what Davis thinks should be done to improve medical care in the United States. This part also is interesting factually as well as conceptually. Davis states the case for compulsory national health insurance forcefully, but quite in its logical place within the volume as a whole. This chapter in no way colors the total work; and the book would have been incomplete without it.

I predict that this volume will go through many revisions, but that it will never be replaced. The field of medical care now has too many and too technical special aspects for any newcomer to achieve a mastery of the whole with justice to the parts. Every expert in a part of the field will have reason to dispute Davis; I challenge anyone to offer a substitute for his underlying logical structure.

The book has a useful selected bibliography listing fugitive and out-of-print materials as well as the standard works. The style is readable, if a bit discursive. Through all of the text the personality of the author is apparent—a reformer of the Old School, interested in "expedited gradualism," who concludes by saying "The evils of today should by no means be tolerated because they were worse yesterday" (p. 434).

TITLES OF NEW BOOKS

Economic Theory; General Economics

BECKWITH, B. P. *Marginal-cost price-output control—a critical history and restatement of the theory.* (New York: Columbia Univ. Press. 1955. Pp. viii, 283. $5.75.)

BLODGETT, R. H. *Our expanding economy—an introduction* (New York: Rinehart. 1955. Pp. xv, 973. $6.)

BOULDING, K. *Economic analysis.* 3rd ed. (New York: Harper. 1955. Pp. xx, 905. $6 50.)

With regard to the new edition, the author says in the preface: "Macroeconomics now takes a firmly equal place with microeconomics. There is more attention to problems of dynamics and growth Marginal analysis has been moved in the direction of greater generality."

CHAMBERLAIN, N. W *A general theory of economic process* (New York: Harper 1955. Pp. viii, 370. $5.)

COWARD, D *Økonomisk risiko og usikkerhet* (Economic risk and uncertainty). (Bergen: Bedriftsøkonomens Forlag. Oslo. 1953. Pp. 349)

FUZ, J. K *Welfare economics in English Utopias—from Francis Bacon to Adam Smith* (The Hague: Martinus Nijhoff. 1955. Pp viii, 113. *f.* 7 —.)

GEMMILL, P. F. *Current introductory economics* (New York: Harper. 1955 Pp. xii, 711)

A successor to the author's *Fundamentals of Economics* "Teachers who have used *Fundamentals* will find in *Current Introductory Economics* a good deal of familiar material; but it is material that remained after the earlier book had been thoroughly reexamined, and its various parts deleted, expanded, rearranged, or rewritten whenever such treatment gave promise of improving it eight chapters have been added. . . ." (From the author's preface)

HECKSCHER, E F. *Merkantilismen* 2nd rev ed 2 vols (Stockholm Norstedts 1953. Pp 444, 383 Sw. cr. 96)

HEIMANN, E *Vernunftglaube und Religion in der modernen Gesellschaft—Liberalismus, Marxismus und Demokratie.* (Tubingen: J. C. D. Mohr [Paul Siebeck]. 1955. Pp xiii, 315. DM 19 80.)

KEYNES, J. N *The scope and method of political economy* Reprint of 4th ed. (New York: Kelley & Millman. 1955 Pp xiv, 382. $6)

LAMONT, W D *The value judgment* (New York: Thomas Nelson. Edinburgh: University Press. 1955 Pp xv, 335 25 s.)

Handbook of statistical organization. UN Stat. Office stud. in methods ser. F no 6. (New York: Columbia Univ. Press. 1955. Pp. iii, 138. $1.50.)

This handbook is based largely on selected papers presented at an International Seminar on Statistical Organization held in October, 1952. It "is designed to meet the need for information and guidance in matters relating to the organization and operation of national statistical services" (from the Introduction).

Input-output analysis—an appraisal. Studies in income and wealth. Vol. XVIII By the Conf. on Research in Income and Wealth. (Princeton: Princeton Univ. Press, for the Nat. Bur. Econ. Research. 1955. Pp. x, 371. $7.50)

Methods of national income estimation. UN Stat. Office stud in methods ser. F no. 8 provisional issue. (New York: Columbia Univ. Press. 1955. Pp 58 50¢.)

"This handbook has been prepared as an aid in the estimation of national income statistics, with the needs of the less developed countries especially in mind. The emphasis, as suggested by the title, is placed on methods of measurement rather than on concepts and definitions. . . . The matter of concepts, definitions and the structure of accounts has been the subject of separate study and is dealt with in other publications of the Statistical Office, notably in A System of National Accounts and Supporting Tables and in Concepts and Definitions of Capital Formation." (From the Introduction.)

Proceedings of the Business and Economic Statistics Section—papers presented at the 114th annual meeting of the American Statistical Association, Sept. 10-13, 1954, Montreal, Canada. (Washington: Am. Stat. Assoc 1955. Pp. 255.)

Sennholz, H. F. *How can Europe survive?* (New York: D Van Nostrand. 1955. Pp. iv, 336. $4.)

The author is concerned with economic and political aspects of the movement towards European unification After an introductory part, Part II is devoted to "a selection of famous doctrines and plans of unification" "The several institutions for the promotion of unity set up by Western European governments are analyzed in Part Three They are examined in the light of the compatibility of their functions with the true principles of unification . . In Part Four, the author is searching for a world economy of peaceful cooperation, a world without trade barriers and restrictions upon the liberty of man, a world without incentives for war and aggression." (From the Introduction.)

CHINOY, E. *Automobile workers and the American dream.* (Garden City: Doubleday. 1955. Pp. xx, 139. $3.)

In the author's words, "This book reports an investigation of what opportunity looks and feels like to a group of automobile workers in a middle-sized midwestern city. It is an attempt to explore how these men live out their versions of the American dream in a world in which there is a palpable disparity between their experience and the prevalent

myth." By the American dream the author means the idea that there is equal opportunity for all to rise to the top in the American system. The approach of the author is essentially that of the sociologist.

NOTES

Erratum: The name of the nominee for president of the American Economic Association published in this section of the June 1955 number of the *Review* erroneously appeared as Edwin E. White. The nominee for the office of president in 1956 is Professor Edwin E. Witte, of the University of Wisconsin.

SIXTY-EIGHTH ANNUAL MEETING OF THE AMERICAN ECONOMIC ASSOCIATION

Hotel Commodore, New York City, December 28-30, 1955

Preliminary Announcement of the Program

Nearly half of the sessions of the program for this year are centered upon the economic growth of the United States, that is, on the problem of keeping the United States economy moving onward and upward. This means that both the secular and the periodic phases of the problem will be explored. Nine of the remaining sessions, including four that are joint with other associations, are primarily international or foreign in their scope and incidence Since this is the year when the Association meets jointly with other social science associations, twelve sessions will be held jointly with other associations, in addition to the two joint luncheon meetings. The papers and discussions of eighteen sessions will be published in the Proceedings.

Wednesday, December 28, 1955

10:00 A.M. Meeting of the Executive Committee

12:30 P.M. Luncheon Meeting of the Executive Committee

12:30 P.M. Luncheon Meeting (Joint with the American Statistical Association)
THE ECONOMIC OUTLOOK
Speakers: EDWIN G. NOURSE, Joint Council on Economic Education
ALAN H. TEMPLE, National City Bank of New York

2:30 P.M. Economic Growth. I. STATEMENT OF THE PROBLEM OF KEEPING THE UNITED STATES ECONOMY MOVING FORWARD, BUT STEADILY
Chairman: CALVIN B. HOOVER, Duke University
Papers: Scope and Objectives of Ten Sessions on Economic Growth
THE CHAIRMAN
The Economic History of the United States in These Terms from 1870 to 1955, but Particularly since 1900
MOSES ABRAMOVITZ, National Bureau of Economic Research and Stanford University
The Goals of Economic Growth in the United States—Economic and Other Social Priorities
PAUL T. HOMAN, University of California at Los Angeles
Discussion: WILLIAM J. FELLNER, Yale University
FREDERICK V. WAUGH and JAMES P. CAVIN, U. S. Department of Agriculture

THE ECONOMIC POTENTIALS OF LATIN AMERICA
Chairman: THEODORE W. SCHULTZ, University of Chicago
Papers: Developments Under Way, Obstacles and Problems, and Potentials
SUNE CARLSON, United Nations
Some Policy Lessons for Economic Development in this Part of the World
THEODORE W. SCHULTZ, University of Chicago

Discussion: GEORGE GARVY, Federal Reserve Bank of New York
EMILIO G. COLLADO, Standard Oil of New Jersey
SIMON ROTTENBERG, University of Chicago

THE CHANGING PATTERNS OF COMPETITION IN TRANSPORTATION AND OTHER PUBLIC UTILITY LINES
Chairman: EDWARD W. MOREHOUSE, General Public Utilities Corporation
Papers: The Competition of Long-Distance Motor Trucking—Farm and Industrial Products and Supplies
CHARLES A. TAFF, University of Maryland
The Partnership Policy in Regional Power Planning
WALTON SEYMOUR, Washington, D.C.
Federal Regulation of Natural Gas Producers and Gatherers
MARTIN L. LINDAHL, Dartmouth College
Discussion: FRED V. STONE, Canadian Pacific Railway

THE THEORY OF GOVERNMENT EXPENDITURES (Joint with the Econometric Society)
Chairman: OSWALD BROWNLEE, University of Minnesota
Papers: Aspects of the Abstract Theory of Public Expenditures
PAUL A. SAMUELSON, Massachusetts Institute of Technology
A Multiple Theory of the Budget
RICHARD A. MUSGRAVE, University of Michigan
Discussion: WALTER S. SALANT, Brookings Institution
JULIUS MARGOLIS, University of California

8:30 P.M. Economic Growth II: THE PRODUCTION AND CONSUMPTION ECONOMICS OF ECONOMIC GROWTH
Chairman: WILLARD L. THORP, Amherst College
Papers: The Production Economics of Economic Growth
W. DUANE EVANS, Bureau of Labor Statistics
The Consumption Economics of Economic Growth
RUTH P. MACK, National Bureau of Economic Research
The Value and Pricing Aspects
ARYNESS JOY WICKENS, Bureau of Labor Statistics
Discussion: EARL O. HEADY, Iowa State College
ROBERT FERBER, University of Illinois

CURRENT ECONOMIC THOUGHT AND ITS APPLICATION AND METHODOLOGY IN CONTINENTAL EUROPE
Chairman: ALEXANDER GERSCHENKRON, Harvard University
Papers: The Scandinavian Countries
HANS BREMS, University of Illinois
Holland
HANS THEIL, University of Chicago
Italy
FRANCISCO MODIGLIANI, Carnegie Institute of Technology
Eastern Europe Outside of Russia
Question Period Led by the Chairman

ARE UNION PRACTICES MONOPOLISTIC? (Joint with the Industrial Relations Research Association)
Chairman: RICHARD A. LESTER, Princeton University
Paper: To be announced
EDWARD S. MASON, Harvard University

Panel: PETER O. STEINER, University of California
JULES BACKMAN, New York University
PETER HENLE, American Federation of Labor
CHARLES C. KILLINGSWORTH, Michigan State College
MINEAR SARGENT, Caterpillar Tractor Company

TARIFF POLICY FOR THE U.S.A., A STRONG RICH COUNTRY (Joint with American Farm Economic Association)
Chairman: An Introductory Statement. CHARLES P. KINDLEBERGER, Massachusetts Institute of Technology
Panel: DON D. HUMPHREY, Duke University
LAWRENCE W. WITT, Michigan State College
RICHARD M. BISSELL, Washington, D.C.
DENNIS W. FITZGERALD
DONALD B. MARSH, McGill University
Summary Statement by the Chairman

Thursday, December 29

9:30 A.M. Economic Growth. III. INCOME DISTRIBUTION ASPECTS OF EXPANDING PRODUCTION AND CONSUMPTION
Chairman: PAUL SAMUELSON, Massachusetts Institute of Technology
Papers: Distribution of Aggregate Income between Taxes and Other than Taxes, and among Consumption, Savings, and Capital Formation
Distribution of Incomes of Business Firms among Taxes, Dividends, and Retained Earnings
JOHN LINTNER, Harvard University
Discussion: LLOYD ULMAN, University of Minnesota
LORIE TARSHIS, Stanford University

Economic Growth. IV. THE SHORTENING WORK WEEK AS A COMPONENT OF ECONOMIC GROWTH (Joint with the Industrial Relations Research Association)
Chairman: GERHARD COLM, National Planning Association
Paper: The Alternatives
CHARLES STEWART, United States Department of Labor
Panel: CLARK KERR, University of California
SOLOMON BARKIN, Textile Workers Union of America
NELSON N. FOOTE, University of Chicago
FOREST F. HILL, Cornell University
LESTER KELLOGG, Deere and Company

REPORT OF THE ATTORNEY-GENERAL'S COMMITTEE ON ANTI-TRUST POLICY
Chairman: CORWIN D. EDWARDS, University of Chicago
Papers: Market Power and Business Conduct: Some Comments on Anti-Trust Policy
EDWARD S. MASON, Harvard University
Enforceable Competition: Unruly Reason or Reasonable Rules
KINGMAN BREWSTER, Harvard University
Competition: Hard or Soft
CLAIR WILCOX, Swarthmore College
Discussion: GEORGE W. STOCKING, Vanderbilt University
ALFRED E. KAHN, Cornell University
CLARE E. GRIFFIN, University of Michigan
GEORGE J. STIGLER, Columbia University

Economic Growth. X. URBAN GROWTH AND DEVELOPMENT (Joint with Regional Scientists)
Chairman: WALTER ISARD, Massachusetts Institute of Technology
Papers: The Spread of Cities
DONALD J. BOGUE, University of Chicago
Changes Within Cities
CHESTER RAPKIN, Columbia University
Discussion: RICHARD U. RATCLIFF, University of Wisconsin
MARTIN MEYERSON, University of Pennsylvania
JOSEPH L. FISHER, Resources for the Future, Inc.

THE DYNAMICS OF FOOD RETAILING (Joint with the American Marketing Association and the American Farm Economic Association)
Chairman: JOSEPH ACKERMAN, Farm Foundation
Papers: Movements in the Retail Distribution of Food in the United States
ROBERT W. MUELLER, Editor, *The Progressive Grocer*
Some Recent Developments in Food Retailing in Europe
HERBERT EKLOEH, Germany
Supplementary Statements: WILLIAM APPELBAUM,
RICHARD H. HOLTON, Harvard University

2:30 P.M. Economic Growth V. THE INCREASE-OF-CONSUMPTION PART OF ECONOMIC GROWTH
Chairman: ASHER ISAACS, University of Pittsburgh
Papers: Price and Income Elasticity of Demand as Determinants of the Increase-of-Consumption Part of Economic Growth
ELIZABETH GILBOY, Harvard University
The Potentials of the Shifting of Price- and Income-Elasticity Demand Curves in Order to Keep the Economy Moving Forward
JAMES DUESENBERRY, Harvard University
Brief Reports on Current Research Projects in Consumption and Demand
JOHN B. LANSING, University of Michigan
IRWIN FRIEND, University of Pennsylvania
JAMES TOBIN, Yale University
ROBERT SCHLAIFER, Harvard University

Economic Growth VI. GOVERNMENT EXPENDITURES AND ECONOMIC GROWTH
Chairman: ROY BLOUGH, Columbia University
Papers: Government Expenditures and the Long-Run Goals of Economic Growth
C. LOWELL HARRISS, Columbia University
Government Expenditures and the Short-Run Goal of Steady Growth
DAN T. SMITH, Harvard University
Discussion: WALTER FROELICH, Marquette University
JOHN F. DUE, University of Illinois
MARION CLAWSON, Resources for the Future, Inc.

THE POPULATION SPECTRE—RAPIDLY DECLINING DEATH RATES IN DENSELY POPULATED COUNTRIES (Joint with the American Farm Economic Association)
Chairman: MERRILL K. BENNETT, Food Research Institute, Stanford University
Papers: A Statement of the Situation
KINGSLEY DAVIS, University of California
Food and Agricultural Possibilities
CHARLES E. KELLOGG, United States Department of Agriculture
Nonagricultural Possibilities
REUBEN E. SLESINGER, University of Pittsburgh

Possible and Probable Outcomes, and Courses of Action to be Considered
JOSEPH J. SPENGLER, Duke University
Question Period Led by the Chairman

FEDERAL RESERVE BOARD COMMITTEE REPORTS: I. SAVING STATISTICS AND CONSUMER EXPECTATIONS
Chairman: RALPH A. YOUNG, Federal Reserve Board
Papers: RAYMOND GOLDSMITH, National Bureau of Economic Research
JAMES TOBIN, Yale University
Discussion: GEORGE KATONA, University of Michigan
MORRIS COHEN, National Industrial Conference Board

8:30 P.M. *Chairman:* THOMAS NIXON CARVER, Santa Monica, California
PRESIDENTIAL ADDRESS: Agriculture in the Economy of the Nation
JOHN D. BLACK, Harvard University

Friday, December 30

9:30 A.M. Economic Growth. VII. THE MONETARY ROLE IN BALANCED ECONOMIC GROWTH
Chairman: MILTON FRIEDMAN, University of Chicago
Paper: CHARLES R. WHITTLESEY, University of Pennsylvania
Panel: IRA O. SCOTT, University of Minnesota
PAUL W. MCCRACKEN, University of Michigan
HOWARD S. ELLIS, University of California
EDWARD S SHAW, Stanford University

Economic Growth. VIII HIGHWAY DEVELOPMENT AND FINANCING (Joint with the American Finance Association)
Chairman: WALTER W. HELLER, University of Minnesota
Paper: Highway Development and Financing as a Case Study in the Problem
THE CHAIRMAN and OSWALD H. BROWNLEE, University of Minnesota
Panel: HAROLD M. GROVES, University of Wisconsin
JAMES C. NELSON, Washington State College
ARNOLD M. SOLOWAY, Harvard University
WILLIAM D. ROSS, Louisiana State University
HAROLD W. TORGERSON, Northwestern University

ECONOMICS IN THE CURRICULA OF SCHOOLS OF BUSINESS
Chairman: RAYMOND T. BOWMAN, University of Pennsylvania
Papers: Over-all Statement of the Problem and Situation
NEIL H. JACOBY, University of California at Los Angeles
By Universities: GEORGE LEE BACH, Carnegie Institute of Technology
EDWARD H. LITCHFIELD, Cornell University
DONALD W. O'CONNOR, Columbia University
ARTHUR M. WEIMER, University of Indiana
EWALD T. GRETHER, University of California at Berkeley

THE LAND TENURE SITUATION AROUND THE WORLD (Joint with the American Farm Economic Association)
Chairman: JOSEPH ACKERMAN, Farm Foundation
Introductory Paper: KENNETH H. PARSONS, University of Wisconsin
Papers by Individual Countries:
India and Pakistan
LEE R. MARTIN, North Carolina State College
Spain and Southwest Europe
JOSÉ VERGARA, Spanish Embassy

Australia
THOMAS H. STRONG, Bureau of Agricultural Economics, Australia
Mexico
EDMUNDO FLORES, *Nacional Financiera*, Mexico City
Japan
WOLF LADEJINSKY, Department of State
Question Period Led by the Chairman

FEDERAL RESERVE BOARD COMMITTEE REPORTS: II. INVENTORY STATISTICS, INVESTMENT EXPECTATIONS, AND GENERAL BUSINESS EXPECTATIONS
Chairman: MARTIN GAINSBRUGH, National Industrial Conference Board
Papers: GEORGE W. TERBORGH, Machinery & Allied Products Institute
J. FREDERICK DEWHURST, Twentieth Century Fund
Discussion:

12:30 P.M. Luncheon Meeting (Joint with the American Finance Association)
REFLECTIONS OF A CENTRAL BANKER
Speaker: ALLAN SPROUL, President, Federal Reserve Bank of New York

2:30 P.M. Economic Growth IX. UNEMPLOYMENT AS A PHASE OF ECONOMIC GROWTH
Chairman: EDWIN G. NOURSE, Joint Council on Economic Education
Paper: The Structure of Unemployment in the United States
ISADOR LUBIN, Industrial Commissioner, State of New York
Discussion: EWAN CLAGUE, United States Department of Labor
LAZAR TEPER, International Ladies Garment Workers Union
Paper: Measures to be Taken at Different Levels and Distributions of Unemployment
ALBERT G. HART, Columbia University
Discussion: ALBERT S. EPSTEIN, International Association of Machinists
Question Period

ECONOMIC THOUGHT AND ITS APPLICATION AND METHODOLOGY IN THE EAST
Chairman:
Papers: India
MAX F. MILLIKAN, Massachusetts Institute of Technology
Pakistan
OVERTON H. TAYLOR, Harvard University
Japan
MARTIN BRONFENBRENNER, University of Wisconsin
The Middle East
DON PATINKIN, The Hebrew University, Israel
Question Period Led by the Chairman

THE ECONOMIC POTENTIALS OF AFRICA
Chairman: JOHN W. GARDNER, Carnegie Corporation of New York
Papers: Economic Development, The African Scene
WILLIAM A. HANCE, Columbia University
Anthropological Factors in the Economic Evolution of Africa
MELVILLE J. HERSKOVITZ, Northwestern University
Discussion: LLOYD G. REYNOLDS, Yale University
CALVIN W. STILLMAN, University of Chicago
SANFORD A. MOSK, University of California

MINIMUM WAGES AND OTHER LABOR STANDARDS CONSIDERED IN RELATION TO ECONOMIC GROWTH IN UNDERDEVELOPED COUNTRIES (Joint with the American Farm Economic Association)

Chairman: Karl Brandt, Food Research Institute, Stanford University
Papers: In Factory Employment
Elmo P. Hohman, Northwestern University
In Small-scale and Cottage Industry
Jeanne S. Mintz, New York City
In Agriculture
Louis J. Ducoff, United States Department of Agriculture
Supplementary Statements: Egbert DeVries, International Bank for Reconstruction and Development
John Windmuller, Cornell University
J. Henry Richardson, University of California.

5:00 P.M. Business Meeting
6:00 P.M. Dinner Meeting of the Executive Committee

The First Congress of the International Economic Association, Rome, Italy, September 6-11, 1956

The International Economic Association came into existence in 1950, through the efforts of a group of European and American economists convened by UNESCO. In constitution it represents a federation of the various national associations in the field of economics, including the American Economic Association. Its Council is nominated by the national associations, and four representatives of the American Economic Association serve on it. The officers of the International Economic Association for the current year are as follows: *Honorary Presidents:* J. M. Clark, Luigi Einaudi, Gottfried Haberler, A. C. Pigou, and Arthur Spiethoff; *Executive Committee:* Howard S. Ellis (President), Leon Dupriez (Vice-President), Austin Robinson (Treasurer), Walter Hoffmann, Emile James, Erik Lindahl, Volrico Travaglini, C. N. Vakil, Xenophon Zolotas; *Secretary:* Helene Berger-Lieser, Paris VIII, 7, Rue de Miromesnil.

A main feature of the work of the International Economic Association has been a series of small conferences of persons making noteworthy contributions to certain defined fields of economics. The first conference was concerned with the problems of long-term international balance; the second with methods of teaching economics; the third with the regulation of monopoly; the fourth with the business-cycle in the postwar world; the fifth with the determinants of economic progress; the sixth with wage determination; the seventh - being held in September, 1955—is concerned with problems of migration. The working papers and discussions of these conferences have been or are to be publishd.

These small conferences have been of very great value in bringing together workers in the same fields, many of whom had never previously met each other, and in clearing up ambiguities and misunderstandings But they have inevitably been confined to small numbers of selected experts, and it has not been practical to invite many who would have enjoyed opportunities to meet and discuss

The purpose of the Rome Congress is to provide a wider opportunity for any members of the twenty-three associations that compose the International Economic Association to take part in the work of the Association. All members of the American Economic Association are entitled to take part in the Congress. The program follows:

Thursday, September 6. Opening of the Congress. Stability and Progress: The Richer Countries' Problem, by Sir Dennis Robertson.

Friday, September 7. Stability and Progress: The Poorer Countries' Problem, by Jacob Viner.

Saturday, September 8. The Quest for Stability: The Real Factors, by François Perroux

Monday, September 10. The Quest for Stability: The Monetary Factors, by Gottfried Haberler.

Tuesday, September 11. International Stability and the National Economy, by Erik Lundberg.

A fee of $5.00 will entitle participants to receive all Congress papers, which will be available in Rome and not distributed in advance. Meetings will take place in the Faculty of Law of the University of Rome, facilities of which will be available to the IEA by

courtesy of Professor G. Ugo Papi, Rector of the University of Rome. Each day's sessions will open with an address, the text of which will be available to Congress participants in the two official languages, French and English. The subsequent discussion of the address will, in each case, be introduced by two speakers chosen in advance. The discussion will be interpreted into the two official languages.

On behalf of the IEA, the Italian Tourist Agency CIT will take care of registration and the collection of the conference fee, as well as travel arrangements and hotel reservations. Those wishing to participate should as soon as possible write to CIT (Congress Department), Piazza Colonna 193, Rome, Italy. They will receive an application form, together with details of reduced fares and of hotel accommodation available in Rome.

International Committee for Social Sciences Documentation

This Committee was created at the end of 1950 as a result of meetings of experts convened by UNESCO. The purposes of the Committee are the coordination and improvement of existing bibliographic instruments for the social sciences, and the creation of new bibliographic instruments in this area. It is the intention to establish periodical comprehensive bibliographies for each major discipline; and to publish periodicals containing abstracts and specialized bibliographic essays, at least for certain disciplines.

Annual international bibliographies have been undertaken for sociology (Volume I, covering the year 1951, appeared in 1952), for political science (Volume I, for 1952, appeared in 1954), and for economics (Volume I, covering 1952, appeared early in 1955). *International Political Science Abstracts*, a quarterly journal of abstracts of articles in the field of political science, has appeared regularly since 1951. Since 1952, bibliographic reports on important research trends in sociology have been published twice a year in *Current Sociology*. The Committee has prepared an *International Repertory of Social Science Documentation Centers* and *A Selected Inventory of Periodical Publications* (the latter was published by UNESCO in 1951, and the first supplement appeared in 1953); it has edited a *World List of Social Sciences Periodicals* which was published by UNESCO in 1954; and, on an experimental basis, it prepared in 1954 some cumulative lists of works used in the teaching of the social sciences in the universities of the United Kingdom and of Sweden.

The address of the Committee is: Comité International pour la Documentation des Sciences Sociales, 27 rue Saint-Guillaume, Paris 7; and the secretary general is J. Meyriat

Schumpeter Prize Fund

A fund has been gathered by friends of the late Joseph A. Schumpeter to establish a prize to be awarded periodically for original work in the field of economics The Schumpeter Prize in the amount of not less than $1,000 will be awarded once every two years providing that sufficiently meritorious work has come to the attention of the awarding board If sufficient income has accumulated and work of sufficient merit has been found, the awarding board may award prizes in one-year intervals

Anyone who has made an original contribution to economics is qualified to obtain the prize—provided, however, that his contribution falls within those branches of economics in which the late Professor Joseph A. Schumpeter made his most creative contributions For the present, the study of economic development, and its interrelations with historical, social, and political evolution, and the interrelations between economic theory, statistics, and history seem to be the most appropriate; but relevant theoretical work is to be included.

The primary test in awarding the prize is to be the depth and originality of perception Whether the work is an article in a periodical or a full-length monograph is irrelevant

The prize will be awarded by a board consisting of three members of the faculty of economics at Harvard University.

The first award of the newly created Schumpeter Memorial Prize has been made to Professor Ragnar Frisch, of the University of Oslo, Norway, in recognition of his numerous pathbreaking achievements in the fields of economic theory, statistics, and econometrics

Recently elected officers of the Metropolitan Economic Association, New York City, are: president, Nilan Norris, Hunter College; vice-president, C. Lowell Harriss, Columbia University; secretary, Miriam Civic, National Industrial Conference Board; treasurer, Mildred Rendl, General Electric Company.

Deaths

Helen Baker, associate director, Industrial Relations Section, Princeton University, died January 10, 1955.

Walter E. Clark, president of the University of Nevada from 1917 to 1938, died May, 1955.

Bernard H. Hartzell, of Youngstown, Ohio, died January 9, 1955.

Archibald J. Nichol, associate professor of economics in the Wharton School of Finance and Commerce, University of Pennsylvania, died April 18, 1955.

Daniel T. Selko died at Caernarvonshire, Wales, February 27, 1955.

Appointments and Registrations

John F. Adams has been promoted to professor of economics in the School of Business and Public Administration, Temple University.

Quincy Adams has been transferred from the Central Intelligence Agency to an economist post with the Federal Trade Commission

John S. Almeida has been appointed instructor in the College of Business Administration, University of Florida

William H Andrews, Jr., has been promoted from assistant professor to associate professor at Indiana University

Ellis Austin, of Michigan State University, has been appointed assistant professor of economics at the University of Pittsburgh

George Babilot, Carnegie fellow, has been appointed instructor in economics at the University of Oregon.

L. Durward Badgley has been promoted to the position of director of real estate and mortgage research in the Mutual Life Insurance Company of New York

Stephen J. Barres has been appointed instructor in economics at Texas Western College, University of Texas

David W. Belcher has been promoted from associate professor to professor in the School of Commerce, University of Wisconsin.

Philip W Bell, of Haverford College, has been appointed acting director of the International Finance Section, Princeton University. He will serve half-time at Princeton and half-time at Haverford.

Michael H. Belshaw has been appointed lecturer in economics at Barnard College for the current academic year.

Jack F Bennett has resigned as monetary affairs advisor in the Foreign Operations Administration to take a position in the Treasurer's department of the Standard Oil Company of New Jersey in New York

Floyd A. Bond has been selected to receive the Trustees' Distinguished Professorship Award for distinguished service, Pomona College.

Chelcie C. Bosland has been granted a year's leave of absence from Brown University to serve as visiting professor of economics at Northwestern University.

Thomas R. Bossort, Jr, has been promoted from assistant professor to associate professor of management in the School of Business, Indiana University

Elbert V. Bowden, formerly research associate in the University of Kentucky Bureau of Business Research, has been appointed instructor in the department of economics and business administration of Duke University.

Charles T. Bowen has been appointed superintendent of the Consolidated Community School District No. 3, Literberry, Illinois.

Howard R. Bowen, of Williams College, became president of Grinnell College as of July 1, 1955.

Raymond T. Bowman has been granted leave from the Wharton School of the University of Pennsylvania to serve as assistant director of the Bureau of the Budget.

S. E. Braden has been promoted from associate professor to professor of economics at Indiana University. He is also associate dean of the College of Arts and Sciences.

Robert E. Branson, formerly of the Agricultural Marketing Service of the Department of Agriculture, has been appointed associate professor of agricultural economics at Texas A & M College.

Elmer C. Bratt was awarded an honorary degree of doctor of laws at the June 1955 commencement of the University of Nebraska. He is spending the year 1955-56 in Ceylon on a Fulbright grant, making an evaluation of Ceylon's rural development program.

Andrew F. Brimmer, of Harvard University, has joined the research department of the Federal Reserve Bank of New York.

George H. Brown has resigned as professor of marketing in the School of Business, University of Chicago, to become manager of consumer research, Ford Division, Ford Motor Company.

D. H Buchanan, professor of economics, emeritus, has returned to teaching duties at the University of North Carolina for the fall semester.

Norman S. Buchanan, has resigned from the University of California to accept a position as director of the Division of Social Sciences of the Rockefeller Foundation.

Albert Buckberg has been appointed instructor in economics at the University of Michigan.

Orin E Burley has been appointed chairman of the department of marketing and foreign commerce in the Wharton School, University of Pennsylvania

Clarence N. Callender has retired from teaching in the Wharton School, University of Pennsylvania, where he had served as professor of business law.

William J Carson has been granted a leave of absence from the Wharton School, University of Pennsylvania, to serve as director of the National Bureau of Economic Research

Philip W Cartwright is acting executive officer of the economics department of the University of Washington for the current academic year

Hollis B Chenery has been promoted to associate professor of economics at Stanford University.

Sherrill Cleland, of Princeton University, has accepted an appointment as assistant professor of economics at the University of Richmond

Denzel C. Cline has served as acting head of the department of economics, Michigan State University, during the leave of Charles C Killingsworth.

John R. Coleman, of the Massachusetts Institute of Technology, has been appointed associate professor of economics at Carnegie Institute of Technology.

Alfred H. Conrad, of Harvard University, has been appointed assistant professor of economics at Northwestern University

John H. Cover is working on an Asian area study in the Bureau of International Relations of the University of California during the current academic year.

Harold G. Cutright has been appointed professor in the department of marketing, University of Pittsburgh.

Sherman Dallas has been appointed assistant professor, Indiana State Teachers College, Terre Haute.

Lance E. Davis has been appointed instructor in economics at Purdue University.

Karl de Schweinitz has been promoted to associate professor of economics at Northwestern University.

Frank T. de Vyver is retiring from Erwin Mills and is returning to full-time teaching in the department of economics and business administration at Duke University.

Daniel Diamond has been appointed instructor in economics in the School of Commerce, Accounts and Finance, New York University.

D. Lyle Dieterle has been appointed chairman of the accounting department, School of Business, Indiana University, succeeding A. L. Prickett.

William P. Dillingham, of Florida State University, served as a consultant to the Presidential Commission on Veterans Affairs during the summer of 1955.

Evsey D. Domar has been promoted to professor of political economy at the Johns Hopkins University.

Robert Dorfman has resigned from the University of California to take a post as associate professor of economics at Harvard University.

H. M. Douty, chief of the Division of Wages and Industrial Relations, Bureau of Labor Statistics, has received a Rockefeller Public Service Award. He is spending this year abroad, principally at the London School of Economics, engaged in research into problems of wage determination and employment.

C. L. Dunn has been promoted to associate professor of accounting at Louisiana State University.

John S. Dydo, of the University of California, has been appointed instructor in economics at Vassar College for the current year.

Richard A. Easterlin is on leave from the Wharton School, University of Pennsylvania, to serve as research associate at the National Bureau of Economic Research.

Nylen W. Edwards has been appointed assistant professor of transportation at the University of Missouri.

Harry Ernst has been appointed assistant professor of economics at Tufts University

Alexander Firfer is economic consultant to the Administración de Fomento Económico of Puerto Rico on problems of industrial economics, small business and public utilities.

William A. Frank has accepted a position in the office of the executive vice president and general manager, Sperry Gyroscope Company, Great Neck, N.Y.

Charles Gilbert has been promoted from instructor to assistant professor of economics in the School of Commerce, Accounts, and Finance, New York University.

Marion H. Gillim has been appointed executive officer of the department of economics, Barnard College.

William E. Gordon has accepted an appointment as instructor in economics at Marquette University.

Amor Gosfield has been appointed lecturer in the economics department, University of Pittsburgh.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern, University, Evanston, Illinois.

Vacancies

Private and public finance: Ph.D. with emphasis in private and public finance for a large coeducational Catholic university in the Midwest, beginning in fall, 1955. Prefer man with some institutional and some teaching experience. P170

International travel opportunity: The Council on Student Travel invites applications for short-term employment as educational directors on trans-Atlantic ships. Required: educators from the following fields: cultural anthropology, art history, international relations and economics, group work, language, philosophy, recreation, sociology. Conversational ability in one or more of the following: French, German, Greek, Italian. Ability to organize extensive educational program with the help of passenger volunteers. From March to December, 1955, the program will be conducted by the Council for students, tourists and migrants traveling aboard two large passenger ships belonging to one of the major lines. These ships sail regularly from New York to European and Mediterranean ports Job assignments vary from one round-trip sailing to periods of 3-5 months Compensation for these longer periods of service will be regular salary For a single round-trip sailing, full or partial passage, depending upon job requirements. All positions allow for time abroad. For further information, application form, write to. Council on Student Travel, (0-1), 179 Broadway, New York 7, N.Y. REctor 2-0936.

Business administration: Instructor or assistant professor, small Catholic co-educational college in large metropolitan, midwestern center. Salary four to five thousand depending upon qualifications. Should be able to teach management and general business subjects. Ample opportunity for consultation or other outside work if desired. P175

Positions Available at

American Institute for Economic Research, Great Barrington, Massachusetts

Economic Scientist: For continuing advanced research on money-credit and business cycle problems. Should have some knowledge of National Bureau's as well as our work in this area and a background of research. Ph.D. not required provided record of past achievements satisfactory. Successful applicant could be someone still working on Ph.D. thesis or older man who has had extensive experience in the field. Work includes primarily advanced research, some writing, and some seminar guidance of graduate students; no undergraduate teaching. Salary proportionately better than those usual in academic life, because this position requires continuing work entire year except annual 3-week vacation. Unusual long-run opportunity for professional achievement.

Philosopher Scientist: Must be thoroughly grounded in Pierce-Dewey-Bentley line of advance; preferably some experience in analysis of methods evidenced in work of various economists. Job includes continuing critical analysis and basic reconstruction in economics extending Dewey and Bentley's *Knowing and the Known* into description of economic behavior. Some seminar guidance of graduate students in semantics, logic, and the philosophy of scientific method; no undergraduate teaching. Salary proportionately better than those in academic life, because this position requires continuing work the entire year except annual 3-week vacation. Unusual long-run opportunity for professional achievement.

Investment Division: Man qualified in corporate finance, industry studies, accounting, including ratio anaylsis, and investments for our Investment Division. A mature and experienced individual who might be expected to head this aspect of our work in a year or two is sought. This Division prepares the Institute's *Investment Bulletin* and supervises about 200 accounts of individuals; its work is growing rapidly. Some seminar work with our graduate fellows also would be involved.
Note: We wish to find the best men available for the above positions, which are to be filled either this year or in the summer of 1956. Arrangements will be made for conferences with those selected for final consideration. Please send complete statement of education and experience.

Economists Available for Positions

Industrial surveys, personnel management, market research, international economics: Man, 36, Ph.D. Extensive experience with industry, government, advertising, foreign intelligence; various teaching positions; publications; supervisory, editorial, public relations, and lecturing experience. Several foreign languages. Presently employed in New York City headquarters of an international organization. Interested in more responsible position with industrial, commercial company or large university. E450

Business cycles, economic development, public control, transportation: Man, 36, M.A., Ph.D. Ten years of teaching experience at leading institutions; 5 years in industry. Broad familiarity with manufacturing and transport industries; good publication record. Desires teaching and/or research. E528

Economic principles, labor, economic thought, economic history, economic systems, corporation finance, marketing, money and banking: Man, A.M., Northwestern University. Ph.D., Yale University. Fifteen years of economics teaching experience; government experience as price economist. Broad social science background. Project in American economic field completed. Available in September. E536

Economic history, business history, insurance history: Man, 36, Ph.D., New York University. Fourteen years of governmental experience, including those of an advisory and administrative nature; 1 year of teaching experience. Has considerable counseling experience. Desires research, writing, or teaching position. Interested especially in college or university teaching position. Of especial usefulness to life insurance companies as research assistant or historian. E553

International trade, money and banking, investments, market research, labor economics: Man, married; Ph.D. expected this spring. Three years of university teaching numerous fields in economics; 7 years of government research experience in cost and statistical analysis, interindustry relationships, price studies, and labor relations. Interested in teaching position or opening in private industry in management, sales engineering, or foreign trade. Available immediately. E562

International trade, comparative economic systems, urban land economics, marketing, history of economic thought, public finance, money and banking, economic history of Europe: Man, Ph.D. Research fellowships; 7 years of university and college teaching; 4 years of research in federal government. Experience as consultant; multilinguist; extensive foreign travel. Desires teaching or research position. E563

Economic theory, statistics, accounting, money and banking, private and public finance, mathematical economics, international trade: Man, 35; B.S., M.A., Harvard, plus 2 years of graduate study on economic theory and statistics. Now assistant professor of economics and special lecturer of statistics; 6 years of successful college teaching experience. Other experiences include federal government position, university and industry research. Desires better teaching position or responsible statistical research position. E564

Economic history, history of economic thought, economic theory, money and banking, business cycles, international trade and economics, economic geography, corporation finance, investments, marketing: Man, 30, Ph.D., Rotterdam. Has some teaching, industrial, and marketing experience and excellent references. Desires teaching, research, or advisory position in California (San Francisco area). E565

Investment analysis, auditing, budgeting, business finance: Man, 51, J.D. Twelve years of experience in banking, credit and investment transactions; 5 years of experience in auditing large European organizations; 13 semesters of teaching experience as a professor in a fully accredited university in the U.S. Desires position as an investment analyst, controller, or treasurer. Also interested in teaching position. E572

Beginning economics, economic geography, money and banking, credit, retailing, marketing, public utilities: Man, B.S., M.S., plus year of advanced study. Thirty years of experience in teaching and research work; 28 years of teaching in one institution. Being retired under faculty service ruling. Available for part-time, visiting, or supply instructor. Available in September. E573

Economic principles, money and banking, public finance, corporation finance, investments, business cycles, international economics: Man, 37, single; B.S., M.A., requirements for Ph.D. completed and dissertation in progress. Ten years of business experience in commercial banking and insurance underwriting; 2 years of teaching experience at outstanding midwestern schools; currently chairman of department of economics and business at a leading midwestern college. Desires a change to a better position offering greater opportunities for research and development. Stimulating teacher and public speaker. Partial to Southwest (Arizona) or West Coast location. E574

Business statistics: Man, 44, married; Ph.D. Teaching experience in economics and business administration; publications and convention speaking; active in research and consulting. Now teaching in university. Seeks position with greater responsibility. E576

Economic theory and principles, history of thought, public and private finance, and other subjects: Man, under 40, prewar Ph D. Experience in banking, research, government. Listed for years in regional *Who's Who;* contributor to leading journals; trade book on economics of baseball just published; several other books in progress, including theory textbook, but stimulating teaching is chief interest and qualification. Taught 18 years at graduate and undergraduate levels, in several fields, mainly economic theory and finance; 12 years as associate professor; 8 years in present position at large university, with tenure Minimum full professorship. Available now or will negotiate for near future E580

Soviet economy, price theory, national income analysis, economic history, international trade: Man, 34, married; Ph.D. Experience: 4 years of engineering in industry, 2 years of interdisciplinary survey research work at large university, 1 year of interindustry research with private corporation, 1 year of teaching. Publications. Interested in teaching-cum-research position. E582

INTRODUCTION TO BUSINESS

By EDWIN H. SPENGLER and JACOB KLEIN, Brooklyn College. Fourth Edition. 623 pages, $.50

Designed as an introduction to advanced courses in statistics, accounting, management, finance and other offerings in economics. It uses practical situations and illustrative data to give the student a complete, unified picture of all phases of modern business procedure. It acquaints the student with the organization, methods and problems of American industry and helps prepare him for more advanced courses in business and economics.

MODERN MARKETING: Dynamics and Management

By HARRY W. HEPNER, Syracuse University. 599 pages, $6.00

A descriptive orientation to the field which seeks to sharpen the student's awareness of the ways in which the principles of marketing function in new circumstances. It develops an appreciation of the problems of management in regard to modern marketing by integrating student thinking into the larger framework of management's thinking, policies, and programs. Emphasis is on the dynamic forces that affect marketing practices—their basic trends and influences.

ELEMENTARY STATISTICS

For Students of Social Science and Business

By R. CLAY SPROWLS, University of California, Los Angeles. In press.

In this fine new work the author presents a basic and very elementary text for all business, social science, and liberal arts students. Departing from the traditional approach, it follows instead the modern trend toward teaching the principles of statistical inference (or "analytical statistics"), dealing primarily with the formulation of decisions based upon incomplete information. It considers statistics important as a method of inference, and is a course in the scientific method as well as a course in various statistical techniques in common use.

PROBLEMS IN BUSINESS ADMINISTRATION

Analysis by the Case Method

By THOMAS C. RAYMOND, Graduate School of Business Administration, Harvard University. *Harvard Problem Books*. 390 pages, $5.50

The purpose of this distinctive new casebook, which may be used in any undergraduate or graduate college management course, is to let students "learn by doing" how to analyze a business situation and arrive at an intelligent conclusion. The author first leads the student through a sample case, showing him how to analyze it. The cases which follow are organized into four increasingly complex groups: alternatives grow less well-defined, and issues often cross-cut problems in different fields. The fourth and last group places increasing emphasis on detailed programs of action and their implementation.

PROBLEMS OF THE INDEPENDENT BUSINESSMAN

By AUSTIN GRIMSHAW, University of Washington. 428 pages, $6.50

The purposes of this new work are to provide teaching material describing major policy problems actually faced by owner-managers of small businesses; to encourage students and businessmen alike to think their way through to policy recommendations consistent with the facts presented; and to aid students in determining their occupational preferences. Every major segment of the business population, as measured by number of firms in operation, is represented by one or more cases.

MINIMUM PRICE FIXING IN THE BITUMINOUS COAL INDUSTRY

By Waldo E. Fisher & Charles M. James

Two specialists in industry from the University of Pennsylvania set forth the background, problems, and actions of, as well as the conclusions to be gained from, the fullest experiment in minimum price fixing the United States has known—the establishment of minimum prices for coal from 1937 to 1943. As Frederic C. Mills says in his Introduction, "the document they have produced, one may hazard, will occupy a distinctive and enduring place in the literature of political economy."

556 pages. $10

INPUT-OUTPUT ANALYSIS

Studies in Income & Wealth, Volume 18—By the Conference on Research in Income & Wealth

The first systematic and detailed survey of input-output analysis, which is at the same time the newest and most controversial of economic tools. Ten leading authorities on the quantitative analysis of relations among industries present important new findings in their field, suggest the implications of input-output analysis for the entire field of economics, and discuss its usefulness and reliability.

DISTRIBUTION'S PLACE IN THE AMERICAN ECONOMY SINCE 1869

By Harold Barger

An important contribution to our knowledge of a field which only recently has been the subject of careful statistical investigation. The author examines significant changes that have taken place in distribution—in its output of services, its share of the labor force, in productivity, costs, and in the relative importance of wholesale and retail trade and the kind of merchant engaged in each.

Published for the National Bureau of Economic Research.
224 pages. $4.50. Ready in October.
